Mr. Kidd began by showing an irrigating apparatus, with a nickel urethral nozzle and shield. A six-ounce bottle for potassium permanganate solution accompanied it, enclosed in a metal case. For the treatment of gonorrhoea in the male Mr. Kidd regarded this simple portable apparatus as fulfilling the essentials of treatment. In the female, a glass nozzle was substituted and, in addition, the cervix was painted with 2 per cent. flavine. The preponderating majority of cases so treated were cured in six to eight weeks. In the prophylaxis of venereal disease, it was stated that if the urethra was washed out with 1 in 2,000 permanganate solution the morning after exposure to infection gonorrhoea did not develop, while, for syphilis, the use of 33 per cent. calomel cream was practically a certain preventive. Gum elastic catheters were recommended; they should be sterilized by being placed in boiling water for one minute, removed by forceps, and placed on a sterile towel. No oily lubricant should ever be used; "lubafax" was strongly recommended. It was important to desensitize the urethra, but cocaine, on account of its danger, should never be employed. Borocaine (2 per cent.) Mr. Kidd found best, but novocain or stovaine was good. The urethra should be filled with this fluid, a special clip applied to retain it, and four to five minutes allowed for it to act. Permanganate solution was condemned for catheter work, and the lecturer recommended a stock solution of mercury oxycyanide 1 in 30; one drachm of this to one pint of water made a good irrigating solution. The worst cases of cystitis the lecturer had seen were in women on whom a catheter had been passed for retention, following operation, and stress was laid on the inadvisability of leaving catheterization to a nurse. A glass catheter should be used with the urethra in full view. After the bladder was emptied two ounces of oxycyanide solution should be left in. A method Mr. Kidd had found very satisfactory in preventing the persistence of hysterical retention was to inject through the catheter, after washing out the bladder, one ounce of 2 per cent. boroglyceride, and to leave it in; this very frequently induced natural micturition. In acute gonorrhoeal retention the fear was often expressed that the passage of a catheter in this condition might carry the infection to the posterior urethra; there was nothing in this. Infection of the posterior urethra had already taken place; indeed the condition was invariably due to a prostatic abscess. A catheter should be passed at once, and vigorous massage of the prostate would burst the abscess and cure the condition. If sufficient force could not be tolerated at the first attempt it would be successful later. Subsequently Mr. Kidd pointed out that in an ordinary case prostatic massage was frequently overdone; every fifth day was enough, the massage being performed with great gentleness for one to two minutes. An exception was found in gonorrhoeal joint cases, when massage of the prostate every day for ten days would cure the trouble. Stricture was certainly becoming rarer, due to the more efficient treatment of gonorrhoea, but it was a most difficult problem for the general practitioner. The best instrument to try was a whip catheter; if none was available, the next best to try was a fine gum elastic bougie. If one entered successfully, another should be passed alongside it; sometimes three might be inserted together. Urine then trickled past the bougies. As an emergency measure resort might be necessary to suprapubic cystotomy by a hydroceles trocar and cannula, though this was a more dangerous procedure than was generally realized. If facilities were available much the best treatment was immediate internal urethrotomy. Enlarged prostate was probably one of the commonest causes of retention; it occurred after the age of 50, and there were two distinct types. In the ordinary

type—a youngish man who had had symptoms of enlarged prostate—his retention caused him acute pain; that man had good bladder muscle and there was no danger to the kidneys. A gum elastic catheter should be passed (a Marshall's No. 7 was recommended), but it should not be pulled out. It should be tied in and left for two to three days, fitted with a bung, and the bladder washed out once or twice daily with mercury oxycyanide. The dangerous type occurred in older men, who had not complained of difficulty in passing water but had been doing so quite readily every hour or two for some time. The bladder might have reached the umbilicus, but without pain; it had lost all tone. Inquiry would probably elicit a history of "lumbago," and of loss of weight. Such men died like flies if a catheter was passed; the mortality was simply appalling—probably 75 per cent. The bladder should be opened above the pubis, but if all the water was let out the patient would get haematuria and die. Under local, general, or spinal anaesthesia an incision one inch long should be made above the pubis; on separating the muscles the bladder would be seen standing out like a football. A tube should be inserted through a tiny incision for drainage; it should be arranged at such a height that the outflow was really balanced against the kidneys. In this way a gradual emptying, extending over days, would be safely accomplished. *B. coli* infection was common and was invariably a blood infection. It frequently started with rigor, headache, vomiting, a temperature of 104° or 105°, with increased frequency and strangury after four or five days. In men there was often associated infection of the prostate and vesicles. It was common to administer hexamine; this drug irritated and should be avoided at the outset. The treatment consisted in giving potassium citrate in large doses till the urine was alkaline—one drachm every two hours, even in children. If a patient really could not tolerate the citrate alone, then a good combination was potassium citrate, potassium bicarbonate, and magnesium carbonate, of each 20 gr. The patient should be kept in bed and the above treatment continued for ten to fourteen days. When the time came for urinary antiseptics Mr. Kidd recommended hexamine and methylene blue, as being more efficient and more easily tolerated than the former drug alone. The patient should be warned that the urine became blue. Messrs. Burroughs Wellcome and Co. put this combination up in tablets; two of these, four times daily, was recommended. Most cases were cured without vaccines, but these should be tried in cases obstinate to other treatment. In small doses vaccine might be an immunizing agent, but in large doses it was a poison; 5 to 10 or 15 million was an adequate dose, and certainly 20 million should never be exceeded. Mr. Kidd next referred to bladder cases, with an open wound, in which it was necessary to keep the urine acid, to prevent serious infection, and he strongly recommended in preference to acid sodium phosphate boric acid, 5 gr. in a tumbler of water (it dissolved slowly) four times a day. The bladder should be washed out frequently, and hexamine and methylene blue be given, six to eight a day for six to eight weeks.

Reports of Societies.

OVARIAN NEOPLASMS.

A MEETING of the Section of Pathology of the Royal Academy of Medicine in Ireland was held on March 18th, with Professor WIGHAM in the chair.

Dr. DOROTHY H. DOUGLAS showed two specimens of ovarian fibroids. So far as she had been able to gather from the literature ovarian fibroids were infrequent. They were usually unilateral, pedunculated, and torsion of the pedicle was liable to occur owing to their weight, with ensuing oedema and necrosis, but this had not occurred in either of her cases. The etiology of these tumours was uncertain. Among some 960 gynaecological structures removed by operation at the Coombe Hospital since January, 1923, there had been only two ovarian fibroids. The histories were as follows:

A woman, aged 54, had been married thirty-one years, and had had ten children and one abortion. The last pregnancy was a full-term one twelve years previously. She had a normal menstrual

history and the menopause had occurred at the age of 46. She was admitted to hospital complaining of a "swelling in the stomach." At the operation a large hard tumour was removed from one ovary; there was no history of any other abnormality. The tumour, a solid fibroid, weighed 3 lb. There was no sign of any remaining normal ovarian tissue, and the tumour was attached by a broad untwisted pedicle. Microscopically it showed typical oedematous fibroid structure, with myxomatous degeneration in places.

The second patient, aged 63, had been married thirty-eight years and had had one child thirty-seven years previously; no abortions. Her menstrual history was normal and the menopause had occurred at the age of 43. She was admitted to hospital complaining of a "swelling in the stomach" which had lasted for four months; on vaginal examination the tumour could be felt as a hard mobile mass filling up the pelvis. Laparotomy was performed and the tumour removed with the ovary of the opposite side, which was cystic. The tumour had the size of a large Jaffa orange and was attached by a very short pedicle; microscopically it showed the typical fibroid structure, it was very oedematous, and the cell nuclei had almost entirely disappeared. The ovary of the opposite side was small and showed cystic degeneration with commencing papillomatous formation.

Both patients made uneventful recoveries.

Dr. BETHEL SOLOMONS thought that "fibroid" was a bad term, and that evidently these tumours were fibromas, which comprised 2 per cent. of all ovarian tumours. Bearing in mind the fact that there were three classes of this type of tumour described—where the ovary was wholly replaced by the growth, where the growth was confined to a part of the stroma, and where the fibroma was pedunculated—he inquired to which class the present specimens belonged, and if there was any hydroperitoneum or hydrothorax. Usually there were no symptoms, but the diagnosis was easy, except from a pedunculated uterine myoma in the neighbourhood of the ovary.

Dr. J. LAIT showed several specimens of ovarian tumours.

The first was an ovarian fibroma in which torsion of the pedicle had occurred. He then exhibited three specimens of ovarian teratomata. The first was a large ovarian teratomatous cyst, which, when fresh, had weighed 25 lb. and had measured 11 in. in diameter. It had been removed from a woman, aged 46, and the history recorded that the tumour had been palpable at her last confinement thirteen years previously. During the operation for removal the liver was found to contain numerous apparently secondary cancerous nodules, and there was a large mass adherent to the transverse colon, a portion of which was removed. The cyst was a typical teratomatous ovarian cyst, but contained several nodular projections in its wall. On section these showed the same tumour formation—apparently a glandular carcinoma—as the mass removed from the region of the transverse colon. The second of the three specimens was a small cystic teratoma of typical structure; on one side of the cyst, and quite distinct from it, was a small solid mass. Microscopical sections of this revealed the typical picture of a primary alveolar carcinoma of the ovary. Dr. Lait considered that the two tumours were coexistent. The third specimen was a solid ovarian teratoma removed from a girl, aged 11. Sections showed the heterogeneous grouping of tissues common to such tumours. He believed all solid teratomata of the ovary were malignant.

The next exhibit was a large solid ovarian tumour removed from a girl aged 15. It was a solid smooth tumour, and on section had a greyish-white, homogeneous appearance, with patches of haemorrhage and necrosis. Microscopical examination showed it to be sarcomatous. Lastly he showed a large somewhat lobulated ovarian tumour, removed from a woman aged 40. On section it was solid, but apparently was undergoing cystic degeneration. Microscopical examination revealed that it was a solid carcinoma.

Professor WIGHAM said that Dr. Lait had shown three very different teratomata, two being cystic and one solid. In the first specimen it was difficult to say whether the nodules present were those of a primary cancer or not. As regards the second specimen it was unusual to find two entirely different tumours present in one organ.

Dr. BETHEL SOLOMONS said that one of the difficulties in dealing with this class of tumour was the classification. He had to a large extent adopted that of Frankl, who divided true ovarian tumours into epithelioid, stromatoid, and organoid, subdividing the organoid into benign dermoids and teratoids, and malignant dermoids and teratoids. The correct treatment for malignant ovarian tumours had not been decided. It was his practice in the case of a young woman, where the tumour was localized, to remove the whole ovary and to examine the other; if the latter showed any suspicious macroscopic sign of tumour formation he removed it also. In the case of an elderly woman the uterus was removed with the adnexa. He dwelt on the difficulty experienced in giving a prognosis in some cases of ovarian tumour, for occasionally, when

tumours clinically and microscopically benign were removed, malignant metastases followed. This error could only be obviated by cutting sections of every minute portion of the tumour, a procedure practically impossible in some cases.

Dr. R. J. ROWLETTE discussed the classification of ovarian tumours. When a cystic teratoma became malignant it was generally in the nature of a squamous carcinoma.

X-RAY TREATMENT OF EXOPHTHALMIC GOITRE.

At a meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland on March 26th, the President, Mr. R. C. B. MAUNSELL, in the chair, Dr. MATRICE HAYES read a paper on the x-ray treatment of 100 cases of exophthalmic goitre.

Dr. Hayes reviewed the results of radiotherapy in 90 females and 10 males treated by him between 1911 and 1926. Of these, 62 who completed the course of treatment were cured and able to follow their usual occupations; 14 were improved, comprising 8 who left off treatment before they were finally discharged and 6 still under treatment. For various occupational reasons 16 patients abandoned treatment, and the ultimate results of 8 were unknown. There was recurrence in two cases—in one following encephalitis lethargica, and in the other after influenza. Four patients had had previous surgical treatment; three underwent operation shortly after the commencement of x-ray treatment; one died and another had a toxic adenoma. X-ray treatment was given daily or on alternate days for three weeks; after a month's interval this was repeated. Two or three series of applications were usually sufficient. While statistics of the surgical treatment of the disease were copious and reliable, in the case of radiation treatment they were as yet incomplete, but a comparison of the results obtained indicated that x-ray treatment would probably furnish about the same percentage of permanent cures as surgical treatment in the best hands. The advantages of radiotherapy were that there was no mortality resulting from the treatment; patients would submit to it more readily than to operation; and it was applicable also to inoperable and post-operative cases. Its disadvantages were that the treatment was prolonged and that there was some risk of atrophic changes and telangiectases in the irradiated skin. There was ample clinical evidence from the amelioration which followed radiotherapy to justify its employment on rational grounds as a most useful adjunct in the treatment of Graves's disease.

Dr. T. G. HARDMAN said he was an enthusiastic advocate of this treatment. In June, 1925, he read a paper on the subject; he had been able to collect about sixty cases, and follow up their course for several years. On the whole he thought the results were very satisfactory; he had no mortality rate. Some of his patients he had been unable to trace, but he had since learned that two had been successfully treated by operation. Radiologists only advocated the use of x rays as part of medical treatment, and not as the sole method; in fact, the success of the treatment depended very largely on the strictness of the medical régime. The patients who did best were those treated in private, where it was possible for them to have the absolute rest and follow the strict regime which were so essential. In x ray treatment there was no immediate mortality, the treatment was easy to carry out, and there was no scarring such as followed operation. If x rays were not successful this did not prevent patients from being operated on afterwards, although some surgeons said that operation after such treatment was rendered more difficult owing to the formation of fibrous tissue. In his opinion every patient should be given a chance of x-ray treatment before being submitted to the risk (however small it might be) of operation.

Professor J. M. O'CONNOR said that undoubtedly the thyroid gland had its use and significance in the body, but what this use was it was very hard to say. It was thought at one time that exophthalmic goitre was due to excessive adrenaline in the blood, but this had been proved to be wrong. The estimation of basal metabolism seemed to him to be a very heavy weapon to use for investigating a disease

which, as far as he could see, could be investigated by much more simple methods.

Mr. H. STOKES did not think statistics were really of much value in exophthalmic goitre, because it had only recently been recognized that there were two varieties—toxic adenoma and Graves's disease. The mortality in toxic adenoma was just as high as ever; but with the use of iodine in Graves's disease the mortality had come down to 2 per cent. From reading accounts of these cases treated at the American clinics it might be imagined that the patients came in in a very grave condition, were given iodine for three or four days, were then operated on, were up within a week, and within a fortnight were able to leave the clinics, go back to work, and lead a normal life. He had operated on three cases of Graves's disease recently, and in one case, after three months, the patient had been able to go home to England and return to work, and was now perfectly well. There were undoubtedly cases of well marked Graves's disease which recovered in a remarkably short time; but these were apparently a mixture of toxic adenoma and Graves's disease.

Dr. T. G. MOORHEAD said that before one could estimate the value of any treatment in any disease it was necessary to know what the natural course of that disease was when uninfluenced by treatment, or, in the present case at any rate, only treated by the simplest medical methods, such as rest and sedatives. Information on this point was very scanty. As regards actual mortality from the disease, no reliable figures existed showing the mortality incidence. Campbell had studied the death rate throughout Great Britain and Ireland, and concluded that roughly ten persons per million living died of exophthalmic goitre annually, though there was considerable variation in different districts. In 1922, in the Free State, 22 deaths were recorded, and in the following year 18. It was worth noting that of these, 24 deaths occurred above 40 years of age, from which it might be deduced that death usually resulted after many years of illness, inasmuch as most cases of Graves's disease were encountered in the earlier years of life. The Free State figures worked out at roughly seven deaths per million living. It was obvious, however, that none of these figures gave any information regarding the number of deaths in proportion to the number of people who suffered from the disease. Marion Read, who observed 100 cases over a period of about six years, had reported altogether six deaths, and of these four immediately followed surgical treatment. From these scanty figures it might be concluded that the medical death rate was, at any rate, not high. As regards recovery from the disease, it was equally difficult to get reliable figures. It was common knowledge that many patients recovered completely without any treatment, and that, on the other hand, many drifted on as chronic invalids. The general opinion was that about 50 per cent. of recoveries might be expected, and so any treatment that did not improve on that figure might be regarded as of no value. Kessell of New York, indeed, stated that in 82 per cent. of cases that he had observed economic recovery occurred within from four to six months, without any special treatment. He admitted that many of his recovered patients still suffered from considerable disability, and few would agree with his statement that practically all cases tended to recover if left alone. A distinction must be made between the immediate and remote results of surgical treatment. The immediate mortality in some clinics was very low. For example, in the Mayo Clinic, and in Cleveland, the mortality was only about 1 per cent.; but, on the other hand, Kessell and Hyman, in a group of cases collected from various clinics, reported an operative mortality of 9.3 per cent.; and Marion Read, in a small number of cases, had found a mortality as high as 31 per cent. From this it might be concluded that, while surgery under special conditions was comparatively safe, it was by no means safe as a treatment to be universally adopted. The ultimate results following operation were very difficult to determine. Some surgeons would lead one to believe that their cases were completely cured in a month or so after operation; but, on the other hand, in 25 cases, followed for from three to five years after operation,

Marion Read had only reported 2 cases as cured and 9 as improved. The number of cases was, of course, very small to base any statements on, but some importance must be attached to the fact that they were definitely followed up and their condition reported some years after the operation had been performed. Regarding x-ray treatment, the speaker felt most enthusiastic. In a series of 51 private cases reported by him in June, 1925, he had been able to follow up 44. Of these, 2 died badly, showing no response to treatment, and one patient died of influenzal pneumonia. There were 32 complete cures, and 7 very much improved. These figures showed, therefore, 77 per cent. of cures and 15 per cent. improved, or a total of 92 per cent. good results. These results supported those given by Dr. Hayes, and pointed strongly to a combination of medical and x-ray treatment as being the best, and unattended with any danger. Treating cases in this way, he (Dr. Moorhead) had found that acute cases did much better than the milder and more chronic. Private patients, on the whole, did better than hospital patients, presumably because the former were able to obtain more rest and to follow out the details of treatment more thoroughly. The patient should remain in bed, on a restricted protein diet for the first month, and sedatives should be given as required, quinine bromide being particularly useful. He felt strongly that a double course of x rays was all-important. He recommended two periods of treatment, each of about three weeks' duration, with an interval of a month, and he always advised that the thymic region should be radiated as well as the thyroid gland. Of late he had been using Lugol's solution as an addendum to his treatment. It was customary to say that iodine was of particular value in preparing patients for operation. That was doubtless true, but his experience led him to think that it was also of value in hastening recovery by means of x rays. Under iodine the pulse rate came down more rapidly and the thyroid gland became harder. As regards the time required for recovery, he found that in most cases the patients were practically well within six months after commencement of treatment; by well he meant that they had gained weight, had a normal pulse rate, no tremor, no sweating, and were free from nervousness. Traces of goitre often persisted, and often some exophthalmos, but in the absence of other symptoms these were unimportant. All his patients claimed as cures were able to live normal lives and were without disability.

Dr. H. F. MOORE remarked how little was known of the physiology of the thyroid gland, and hoped that the discovery of thyroxin would prove a stimulus to renewed physiological research. The pathology of the gland was in an even worse state of confusion: as a classification of types of enlargement he thought Aschroff's the most suitable. He summarized recent advances in the knowledge of thyroid function, with particular reference to Kendall's work on the thyroxin molecule and its physiological properties. The effect of iodine in hyperthyroidism was of great interest, and any evaluation of treatment should be controlled by clinical observation and estimation of the basal metabolic rate. His patients were all treated under such control by general treatment, iodine, and x rays, but he did not hesitate to have recourse to surgical measures where he thought them necessary.

Sir WILLIAM WHEELER said that the literature on exophthalmic goitre had become quite unwieldy. He traced the progress of surgical treatment of the disease. Of the cases treated between the years 1883 and 1889, Albert Kocher stated that 76 per cent. were cured, and that the mortality was 6.7 per cent. In 1910 the mortality in Kocher's clinic had been reduced to 4.5 per cent. During the last fifteen years immense strides had been made in the surgical treatment, which had brought the mortality in the clinics of Mayo and Crile down to about 1 per cent. Mortality following operation from toxic adenoma was much higher—about 3.48 per cent. The results following surgical operations could be accurately estimated, but figures indicating the ultimate mortality from failure of medical treatment were difficult to ascertain. Sir William Wheeler said he had referred to the

records of seventy-six thyroid cases operated upon since 1910, but his statistics were not accurate owing to the fact that there was confusion between some of the cases of toxic and non-toxic goitre in the hospital records. He had had two deaths from true Graves's disease during this period, one from acute hyperthyroidism in the days before iodine was administered as part of the pre-operative preparation. In this case there was marked exophthalmos, cardiac murmurs, and an irregular pulse. The second case was lost through mechanical difficulties in breathing following an extensive operation; recent technique had eliminated that danger. Nearly all of the cases operated upon by him were those in which medical treatment and radiotherapy had been tried in the first instance, but it was quite possible that a number of these cases had not submitted faithfully to the directions of the physicians. Operations were not shirked in any instance because the disease was advanced and the patients were grave surgical risks, but in such cases the operative procedures were very carefully graded. Graves's disease was a disease of cycles; the stage of development was followed by one of maximum intensity—and then there was retrogression and remission. In the quiescent period an operation was comparatively safe, but during a crisis it should never be performed. He had been impressed by the dramatic improvement which followed a few days after operation in a number of cases. The statistics mentioned in the literature were often faulty owing to the comparison between inefficient surgery and efficient medicine, and efficient surgery and inefficient medicine. To obtain anything like accurate information the statistics of the best authorities—surgical, medical, and radiotherapeutic—should be balanced; if this were done it would be found that the honours were easy. In most cases a combination of methods was desirable. A number of patients were mentioned who had been cured by operation. One, a case of well marked Graves's disease, was operated upon in May, 1911; she was hard at work in a Dublin hotel and had been in perfect health for the last fifteen years. Lugol's solution was an immense help in preparing patients for operation, and would control post-operative remissions; about 5 per cent. of patients did not react to the administration of iodine.

Dr. R. STUMPF said that his experience of treating cases by x rays was that patients considered to be most suitable for operation received a preliminary x-ray treatment about a fortnight beforehand, because it was found that this diminished the operative risk. The majority of cases of exophthalmic goitre were treated by x rays alone, and in 90 per cent. there was either cure or great improvement; if after several radiations there was no improvement then an operation was performed. Ill effects were more likely to occur after radiation by superficial rays than after radiation by deep rays. Cases had been known in which adhesions were present at operation, in spite of the fact that the patients had never been x-rayed; he felt that their presence should not be considered an absolute contra-indication of operation. He always radiated the thymic region, even when the gland was not perceptible. Referring to the frequency of exophthalmic goitre, he said that he treated on an average about five or six cases a month, out of about thirty cases which received ordinary treatment. In simple goitre he always preferred x-ray treatment rather than operation, even in juvenile cases; he had seen several simple goitres in which the tumour had entirely disappeared.

Mr. A. CRANCE referred to the special conditions obtaining in the hospital class of patient which, the discussion had shown, frequently prevented adequate medical or x-ray treatment. In these cases operative treatment showed to advantage. The object of x-ray or surgical treatment was to destroy a portion of the thyroid gland, and if this could be effected safely by surgery it certainly could be so obtained more speedily than by any other method. In certain clinics where these cases were handled by one team, as in the Mayo and Crile clinics, the mortality was in the region of 1 per cent. Given such a mortality, operation was not infrequently indicated in patients who did not respond to x-ray or medical treatment, or in whom, for one reason or another, this could not be carried out.

Dr. O'HEA had treated a large number of cases of exophthalmic goitre by x rays, and thought that his results were roughly about 75 per cent. of cures. Referring to the condition of patients after treatment, he thought that after the first treatment symptoms were exacerbated, but that this was due in the main to fright.

Dr. W. C. STEVENSON said that for a long time now he had not used superficial rays in cases of exophthalmic goitre, because these rays did not affect the pathological cells found in exophthalmic goitre. If deep x rays were given it was impossible for the cells to escape altogether, and these rays tended either to destroy the cells or to stimulate them to return to a more normal condition. The fibrous tissue produced by x rays was not the cause but the result of the cure. Deep x-ray treatment was much more efficient in treating this disease than superficial x-ray treatment, as the former rays penetrated deeper. In some cases he thought that radium had an advantage over x rays, as in cases where very slight but very continued stimulation was required this could be given better by radium than by x rays.

Mr. W. PEARSON said that his experience was that the x-ray treatment in exophthalmic goitre did not make operation any more difficult. Fibrosis was produced, but it was in the stroma of the gland itself, and made no difference so far as operation was concerned. He had never found any difficulty in getting the thyroid gland out cleanly and bloodlessly in cases in which there had been fairly extensive x-ray treatment.

Dr. HAYES, replying, referred to the possible part which thyroxin played in exophthalmic goitre. Referring to antecedent x-ray treatment causing adhesions, and rendering operation more difficult, he said that if this were true it was a thing which radiologists should definitely try to remedy. He did not think that x-ray treatment alone would cure exophthalmic goitre, and the more he saw of the condition the more convinced he was that a radiologist could not cure a case unless he was a good physician. The most essential part of the treatment was the medical regime.

ABDOMINAL ACTINOMYCOSIS.

At a meeting of the Devon and Exeter Medical-Chirurgical Society on March 25th, the President, Mr. R. WORTHINGTON, in the chair, Dr. S. C. SHAW showed a case of abdominal actinomycosis.

Dr. Shaw said that the patient, a man aged 23, had been operated upon two and a half years previously for what appeared at the time to be an ordinary acute attack of appendicitis. The appendix was found to be thick and oedematous, and there was free fluid in the peritoneal cavity. After appendicectomy the man seemed to make a normal recovery, but some two months later a small focus of suppuration showed itself in the scar, and was thought to be a stitch abscess. This did not, however, heal, and subsequently a hard mass was found to be developing beneath the site of the operation incision. Exploration revealed small loculi and matted oedematous tissue, more within than outside the peritoneal cavity. Streptococci only were isolated at first, although actinomycosis was suspected from the nature of the tumour. Eventually a selected nodule was removed under an anaesthetic, and the diagnosis of actinomycosis was confirmed. The mass was now subsiding under large doses of potassium iodide, and the man's general condition was good in spite of the persisting sinus. Vaccine treatment had been of doubtful value in this case.

Dr. R. V. SOLLY gave an account of the infection, and showed the various culture phenomena on the screen. Dr. P. H. SZIKS mentioned a similar case admitted to the Royal Devon and Exeter Hospital many years ago. In this instance there was unfortunately a general infection in addition to that of the appendix, and treatment was of no avail. Dr. W. GONNOR said he believed in pushing the iodide up to extreme doses of even 100 grains three times a day. He also advised that the teeth should receive careful attention. In addition to the use of a specific vaccine, he had often found it of value to give injections

prepared from the complicating organism. For instance, in a case of dysentery with liver abscess, emetino treatment had not been found to clear up the case beyond a certain limit, whereas the pyrexia rapidly subsided after the employment of streptococcal and staphylococcal vaccines. Dr. SHAW mentioned the value of such preparations as thiolistamine and contramine in those conditions which responded as a rule to potassium iodide. Mr. R. WAYLAND SMITH had found contramine of great value in osteo-arthritis, and Dr. W. A. DATE had met with a most promising result after trying manganese butyrate in a case of carbuncle of the face.

Clinical Cases.

Dr. SOLLY gave a pathological demonstration on the following cases, illustrated by microscopic specimens and slides, some of which were projected on the screen. He gave also a short account of the various malignant tumours of the kidney and of the hypernephromata.

1. *Carcinoma of Kidney*.—A man, aged 55, admitted to the Royal Devon and Exeter Hospital in June, 1925, under the care of Dr. F. A. Roper. The man gave a history suggesting that symptoms dated back to 1921, and on admission was practically in *extremis* with cyanosis and dropsy. The liver was much enlarged and there was an extensive tumour in the left loin, distinguishable from the enlarged spleen. At the necropsy in August the primary growth was found to be carcinoma of the kidney arising from the uriniferous tubules, as described by Bland-Sutton; secondary growths were noted in the liver and lungs. The primary growth occupied the greater part of the abdomen and involved both the aorta and vena cava.

2. *Adenoma of Kidney*.—A man, aged 54, was admitted to the Royal Devon and Exeter Hospital, under Dr. Gordon, with a history of under twelve months' illness; he first complained of "swellings in the neck." On admission the symptoms resembled those of the previous case. The necropsy showed an enormously enlarged right kidney with secondary growths in the neck, omentum, and abdominal lymphatics. The growth proved to be a malignant papillary adenoma of the kidney, and to consist of large and small sized cysts, loosely filled with papillary ingrowth of the lining cells. In microscopical section there appeared to be almost an attempt at the formation of tubules.

3. *Hypernephroma*.—From a man aged 40 a large right kidney was removed by lumbar incision (under the care of Mr. Dyball). The tumour showed the well marked capsule of condensed renal tissue characteristic of these growths.

4. *Tuberculosis of the Liver*.—A man, aged 61, was admitted to hospital, under the care of Dr. F. A. Roper, with long-standing tuberculosis of the lungs with asites, oedema of the legs, and enlargement of the liver. The necropsy revealed a much enlarged liver, with many small white nodules and spaces containing green semiliquid material. Nodules were also found in the left loin and in the enlarged glands within the abdomen. This was a tuberculous hepatitis secondary to a primary invasion of the lung.

5. *Endocarditis*.—A man, aged 46, was admitted to hospital under Dr. Gordon. *B. diphtheriae*, or at least a micro-organism closely resembling it, was recovered from the throat. The organism was subsequently considered to be avirulent, and therefore the cause of the progressive cardiac lesion had remained in doubt. The necropsy showed vegetations, probably of recent origin, on the mitral valves only.

The PRESIDENT commented on the doubtful value of vaccines cultivated from the mouth and throat in cases of obscure toxæmia.

Dr. W. GORNON, referring to the cases of renal tumour, said that, as a rule, diagnosis was the only possibility left in these cases, as by the time symptoms showed themselves it was too late to effect a cure. In his own case, quoted by Dr. Solly, the diagnosis of renal tumour was made from a portion of a gland removed from the neck, and in a suspected case of pancreatic tumour the diagnosis had been likewise clinched from the section of a secondary nodule in the skin. Dr. Gordon also reminded the meeting of the reduction in the area of superficial cardiac dullness (Gordon's sign) which was found in carcinoma, but not in sarcoma. In tumours of the bladder it was always well to search carefully for large round vacuolated cells in unstained preparations.

Dr. F. A. ROPER commented on the high figure of the blood urea—537 mg. per c.cm.—in one of the cases of renal tumour, and suggested that the local congestive condition in or near death might have coloured the reading. In the first case quoted by Dr. Solly the man had lived for at least three years and maintained a good general condition, which Dr. Roper attributed to injection of intensive doses of colloidal selenium and copper, continued up to the last few months of the illness.

Reviews.

MOYNIHAN'S "ABDOMINAL OPERATIONS."

THE surgery of the abdomen is of such recent growth that there are still many members of the consulting staffs of London and provincial hospitals who were taught how improper a thing it was to open the sac of a strangulated hernia. Forty years has changed the whole outlook, and Sir BERKELEY MOYNIHAN has been in the advance guard of those who have conquered so much additional surgical territory. He reminds us in the well expressed preface with which he introduces the fourth edition of his great work on *Abdominal Operations* that the book was first published in 1905, and was so immediately successful that a second edition was issued in 1906, and a third in 1915. Rather more than twenty years have thus passed since it first appeared, and in the interval the whole work has been subjected to a very complete revision, but without reducing its size. There is, indeed, only one way to reduce the size of successive revisions of a book on a rapidly progressive science, and that is by rewriting it, not by excising and interpolating. This was the secret of the writers of the time when there were no typists, stenographers, and secretarial assistants. The manuscripts were holographs, and the style was very personal to the writer. Hence the lasting pleasure of Latham's *Clinical Medicine* or Watson's lectures—truly *opera aurea*. But there was perhaps more leisure in those days, and we are thankful that a busy surgeon in the height of his practice should have found time to revise a noble contribution to his own branch of knowledge.

The work deals with the surgery of the stomach, intestines, liver, spleen, and pancreas. Sir Berkeley has deliberately excluded the surgery of such organs as the kidney and bladder, which are partly intraperitoneal and partly extraperitoneal, and he intentionally refrains from discussing the subject of hernia and its operative treatment.

The book is written by a master surgeon, partly for the use and advancement in knowledge of those who, like himself, are engaged actively in the practice of a difficult branch of the art of a general surgeon, and partly for the surgeon who is less experienced and needs guidance in the treatment of conditions which he meets with in the everyday practice of his profession. It is, in fact, an epitome of what is known at the present time of the surgical treatment of abdominal disease. It has the advantage of proceeding from the pen of a single writer—a man of such ripe experience that he has repeatedly performed most of the operations which he describes, and of such sound judgment that he criticizes without bias the various methods which have been proposed, giving satisfactory reasons for the operation he prefers. The work, therefore, will remain as a classic when it has served its immediate purpose. Future generations will read it as an exposition of abdominal surgery in the twentieth century with the same feelings that we now read Paré and Heister, and will perhaps wonder at the variety of methods, the multiplicity of sutures, and the marvellous instruments which were in use in these early days before everything had become standardized.

The first volume opens with a section of "General considerations." These should be read and carefully studied by every operating surgeon, whether he be operating all day and every day in a large general hospital, or only now and again in a small cottage hospital or in the privacy of a nursing home. The section tells of the care to be taken before, during, and after operation, to give the patient the best chance of life and to reduce to a minimum the anxiety, pain, and uncomfortable sequelae which attend all surgical procedures. Everyone is not able to do everything recommended by Sir Berkeley. He counsels perfection, and to carry out all his suggestions would require highly trained assistants, well educated nurses, and the resources of a large and liberally provided institution. It is very useful to have such an ideal presented. It can be striven after even

Abdominal Operations by Sir Berkeley Moynihan. Fourth edition, revised. W. B. Saunders Company, 1926. 239 figures; Vol. II. pp. xvi + 642. (Roy. 8vo 231 figures)

if it cannot be attained, and when it can be followed out even in part much will have been gained by patients whose lot it is to be operated upon in more humble surroundings.

Amongst other "general considerations" is a short chapter on gunshot wounds of the abdomen, in which the experience gained in the war is crystallized in the advice that "the attitude of the surgeon towards a patient who has sustained a severe abdominal crush or blow should be 'look and see' rather than 'wait and see,' unless there is convincing evidence that the lesion is a slight one."

The treatment of tuberculous peritonitis has again become the subject of discussion owing to the claims made by the advocates of the various methods of heliotherapy. Sir Berkeley Moynihan teaches that the disease is usually secondary, and that unless the primary cause be removed in the ascitic fluids, which are alone amenable to operation, a permanent cure will not be obtained. He recommends that in these cases the Fallopian tubes and the appendix be carefully examined, though he speaks figuratively when he says that unless it be removed "no doubt the appendix may continue to pour out its supply of active bacilli into the peritoneal cavity."

"The surgery of intestinal stasis is very carefully considered. Lane's disease is described, and Moynihan concludes his chapter on it with the pregnant words:

"I have thought many hours, read much and worked not a little on this subject of intestinal stasis, and have tried to clear my eyes for the new vision opened to us by Sir Arbuthnot Lane. My experience has been full of surprises; old beliefs so slow to perish have been undermined, and new faiths, so slowly fashioned, have been painfully accepted. And now I do not hesitate to say that the whole question is one which will have to be considered by all of us and to be put to the proof. It cannot be dismissed with a shrug or a sneer, for there is truth in the matter. Amongst much that is dross there lies a nugget of pure gold."

The surgical treatment of gastric and duodenal ulceration and the operation of gastro-enterostomy are considered with great thoroughness and, as might be expected, most lucidly. Sir Berkeley is not content with relying upon his own experience, which is unusually wide, but he takes into consideration the work done by other surgeons in Great Britain, Ireland, the United States, France, and Germany. His account of Finney's operation is made especially clear by the help of some excellent diagrams. Following this are chapters upon the treatment of hour-glass stomach and cancer of the stomach. The first volume ends with a chapter on colotomy and on resection of the small intestine.

The second volume deals with the surgery of the large intestine and intestinal obstruction, as well as operations upon the liver, pancreas, and spleen. Sir Berkeley Moynihan is an acknowledged authority on each of these subjects, but he makes the book more valuable by supplementing his personal knowledge with the literature of the condition about which he is writing. There is no formal bibliography, but the references are scattered throughout the text and are made accessible by a good index of names. The index is accurate, and the references appear to have been verified.

Many of the articles can be read usefully by those who do not profess to be experts in operative surgery; others, like those on the surgery of the liver with its wonderful nomenclature, are only to be read with admiration except by those who are themselves engaged in advancing the confines of surgery. Indeed, Sir Berkeley writes:

"If I might presume to offer any advice to the surgeon who has not great and continued opportunities for practical work, I would suggest to him never to do gastro-enterostomy in the absence of a demonstrable lesion which requires it; and to leave the surgery of the gall bladder alone. The fact that in my own work nearly one-quarter of the patients suffering from cholelithiasis have been operated on before is an argument not against the surgical treatment of the disease, but against an attempt by the inexperienced or untrained operator to deal with conditions which may tax all the energies and call out all the reserves of even the most proficient."

The chapter upon rupture of the intestine is perhaps the most useful, for the surgeon who is not a specialist, in these days when there is an ever-increasing number of accidents from trams and motor cars. The injury is not easy to diagnose. It is apt to be overlooked, and operation is either delayed or is never performed. The result is disastrous, and the figures given by Moynihan are

appalling. Expectant treatment ended, fatally in every instance, and in cases collected by Berry and Paul Giuseppe 17 recovered and 67 died out of 84 patients who had undergone operation. Early operation, therefore, is recommended even when there is considerable doubt as to the exact nature of the injury, and we need not hesitate to conclude that many lives will be saved by following this advice. The chapter on intestinal obstruction is equally valuable, though it shows incidentally a difference between the North Country folk and the people of London. Sir Berkeley says:

"It is still, unfortunately, true that in the very great majority of cases the surgeon is called upon to act in too late a stage of the disease. It is not too much to say that in a consecutive series of 20 cases of average intensity, the condition disclosed at the operation will show that in at least 15 operation has been too long deferred."

This does not happen to a similar degree in London; either the Londoner is more sensitive or nervous about his inside or the North countryman is more long-suffering and of tougher fibre. Possibly it is a relic of the time when Thomas of Liverpool used to treat his cases of intestinal obstruction by an absolute fast of a month. At any rate, Sir Berkeley speaks wisely when he says:

"It is not altogether unsafe to say that an acute abdominal pain which a small dose of morphine does not wholly remove is not rarely due to a lesion within the abdomen that only an operation can relieve. If the condition of the patient is such that a second or larger dose of morphine is speedily called for, the suspicion of the surgeon should be on the alert, and the probability (for it is no less) of the condition being one of mechanical block of the intestine or other grave surgical catastrophe should be borne in mind. It is in no small degree the administration of morphine which is responsible for the disastrous results in cases of acute obstruction."

The last two sections of the book deal with the surgery of the pancreas and the spleen. There is so excellent a word-picture of fulminating pancreatitis that it should be possible for anyone who has read it not only to diagnose this terrible condition, but to distinguish it from acute gastric and duodenal perforation, for which it is so frequently mistaken.

In his prologue to the surgery of the spleen, Sir Berkeley gives a short historical account of early operations. He attributes the first experiments upon the spleen to Malpighi in 1669. Dick Lower at Oxford certainly in 1655, and probably several years earlier, was working at the anatomy, physiology, and surgery of the spleen. It is on record that in 1665 a dirty trick was played upon him, for "a dog's spleen was taken out by Mr. Day and afterwards the same spleen and the dog were stolen by Mr. Hartford and brought up to London and there dissected."

The two volumes are well illustrated with 470 figures, many of them original and drawn by Miss Ethel M. Wright, others copied from various monographs on the subjects of which they treat. The drawings are so clear and helpful as to make the reader forgive the heavy paper on which the book is printed to enable them to be seen to the best advantage. Each volume has two indexes—the one of subjects, the other of persons.

A few points occur for the consideration of the author in any future edition. In volume i (p. 233), is the fluid escaping from a perforated duodenal ulcer mucus, as is stated, or is it the secretion of Brunner's glands, which is not mucus? The French in the reference on page 233 seems to call for revision. Is hedonal (p. 243) still being used at Leeds as an anaesthetic, even "in exceptional circumstances"? It is perhaps hardly necessary to devote nearly a page to the virtues of "isoform" and then to add: "Unfortunately isoform is no longer procurable." Of course, as students are so frequently told, it is unusual for a "patient to complain of no pain," yet the expression is employed on page 79. In the second volume there seems to be no good reason for leaving page 530 blank; if it were necessary to have a blank page at all it should have been 540. Perhaps on the whole it would be better to replace Fig. 356 by Fig. 357, and put 357 where 356 now stands. These are all hypercritical remarks, and such minute blemishes detract nothing from the pleasure and advantage of reading a work which is truly monumental and of the greatest value.

HIP DISEASE.

THE first Robert Jones Prize Monograph augurs well for the success of the scheme which the donor had in mind when he established and endowed the prize. Mr. GEORGE PERKINS's essay on *Tuberculous Disease of the Hip Joint*² forms a valuable contribution to the literature of joint tuberculosis, and should be of practical value to all those who have to treat it. Despite the great improvement which has followed the more general adoption of orthopaedic and gradual methods as opposed to attempts at short cuts to cure by operations, and despite the widespread use of open-air heliotherapeutic treatment, our treatment has not yet reached final perfection.

Since early diagnosis of disease is the first essential of successful cure—which last word we use in its earlier sense—a good many pages are devoted to this branch of the subject and to the distinctions between tuberculous disease and other lesions. Koch's old tuberculin is recommended as a test in doubtful cases, and nearly all cases are doubtful in their early stages, for the transient synovitis or arthritis due to trauma may present all the symptoms of early tuberculosis.

To obtain a movable joint as an end-result it is generally necessary that efficient traction should be maintained during the acute stage, and Mr. Perkins brings forward cogent reasons for preferring fixed traction with body-weight counter-traction to extension with counter-extension against the ischial tuberosity. The benefits of sunshine and fresh air are fully recognized and the precautions necessary in their use are adequately stated.

Mr. Perkins considers carefully the different parts of the articulation to which disease may be limited and the necessary modifications of it that are desirable. Sinuses are not to him such a bugbear as they have been to many surgeons. He has found that there is no great difficulty in preventing secondary infection, and he holds that a sinus only remains open as long as it discharges the useful function of allowing the escape of caseous material and that it will close as soon as no more of this is formed at the focus of the disease.

The slow development of adduction deformity, often taking place long after the patient has been discharged from hospital as an excellent result of treatment, is only possible when the resulting ankylosis is fibrous. Movable joints and those with bony ankylosis in a favourable position are not subject to this late distortion. Hence it is important that the surgeon should be able to diagnose the conditions which allow of fibrous ankylosis. Mr. Perkins shows that it is in cases in which the head of the femur, and not the acetabulum, is affected that fibrous union occurs, and he therefore advocates primary arthrodesis when the diagnosis of this condition is made. Excision of the joint for tuberculous disease may be considered an obsolete method of treatment.

The Pylford splint, a modification of Pugh's modification of Bradford's frame, is preferred to all others by the author, who, however, recommends the plaster spica for certain cases, with the much-needed caution that if it is to fix the hip-joint no padding other than a close-fitting stockinette combination should intervene between the gypsum and the skin of the patient.

A table of end-results in 52 cases will well repay study. From this it appears that in over four-fifths of the cases the head of the femur was affected, and that it was in just these cases that much shortening and adduction were present. The book is illuminated with many excellent radiographic reproductions.

ARTIFICIAL LIGHT TREATMENT.

THE success that has attended the systematic use of sunlight treatment at Leysin, Alton, and Hayling Island, among other places, has turned attention towards the prospect of securing similar advantages from artificial sunlight by means of various forms of electrical radiation. Much use has been made of these artificial means to make up for

² *The Diagnosis, Treatment, and End Results of Tuberculous Disease of the Hip Joint*. By George Perkins, M.Ch.Oxon., F.R.C.S. Eng. Oxford Medical Publications, London. H. Milford, Oxford University Press. 1925. (Demy 8vo, pp. x + 118; 49 figures. 6s. net.)

the lack of natural sunshine which we lament, and which we perversely reduce by the smoky pollution of the atmosphere. The use of these artificial means of securing the remedial influences of sunlight has been attended with unmistakable signs of success, as witness the many papers giving accounts of treatment which have appeared recently in the BRITISH MEDICAL JOURNAL and other medical publications. We have recently received three books which deal with artificial sunlight and its therapeutic uses. The first of these which we shall notice is one by two general practitioners, Dr. ELEANOR H. RUSSELL and Dr. W. KERR RUSSELL, both of Newcastle-on-Tyne. The book, entitled *Ultra-Violet Radiation and Actinotherapy*,³ is well and clearly written, giving a good survey of the subject. Until quite recently this class of work has been done for the most part in large institutions, some specially provided for the purpose, or in general hospitals which have extended existing electrical departments to meet the need. The authors of this book describe the treatment as followed in their own practice, and state their conviction that there is a large field for this work in general practice, and that there is no necessity to relegate it to the specialist. There are chapters on the development of the treatment; on the characters of radiant energy; on the nature and differences of natural and artificial ultra-violet radiation; and on the chemical, physical, and biological properties of these rays. There is an excellent chapter on technique, in which the several types of lamps most commonly used are described and the difficulties that may be met with explained. The descriptions are clear, and can quite well be followed if the reader will take the trouble to examine the actual lamps for himself. Then follow several chapters dealing with the different types of disease which have been treated by the means, including various skin diseases, tuberculosis, nutritional disorders, and so forth. There is a good bibliography. The authors add the warning that "No single therapeutic agent can be a cure-all. Each has its place in medicine, and a new method of treatment is brought into dispute only when extravagant and unsubstantiated claims are made for it."

The second book is a second edition of *Artificial Sunlight and its Therapeutic Uses*,⁴ by Dr. FRANCIS HOWARD HUMPHRIS. The first addition was issued so recently as a year ago, and was then reviewed in our columns. An endeavour has been made in this new edition "to explain the extreme simplicity of the sources and working of ultra-violet radiations, to elucidate the apparent mystery of it, and to explain the details of the treatment so that any ordinary intelligent medical man shall be able to instal an equipment and treat patients with no further instruction than the book contains." The author appears to have well succeeded in his endeavour.

The last of the three books is a little volume of the popular order, written by Dr. EDWIN L. ASH—*Facts about Artificial Sunlight*.⁵ In simple language the character of the spectrum is explained, the nature of that part of it which is put to those special usages, the prospects the treatment holds out, and its limitations. This is followed by an appropriate warning against expecting the treatment to bring about those advantages of general health which can only be secured by all that we mean by good hygiene: light, fresh air, and exercise, which combine to provide that which natural health demands. So far there have been found few dangers in the treatment. Blistering should not occur, except in certain cases where this is designedly aimed at in the treatment of vascular skin lesions. In the hands of the laity there are risks through ignorance of the power of the radiations. Such a case as that published in the BRITISH MEDICAL JOURNAL (April 11th, 1925) by Drs. MacCormac and McCrae is much to the point.

³ *Ultra-Violet Radiation and Actinotherapy*. By Eleanor H. Russell, M.D., B.S.Dunelm, and W. Kerr Russell, M.D., B.S.Dunelm. With Forewords by Sir Oliver Lodge and Sydney Walton. Edinburgh: E. and S. Livingstone. 1925. (Demy 8vo, pp. 262; 77 figures. 10s. 6d. net.)

⁴ *Artificial Sunlight and its Therapeutic Uses*. By Francis Howard Humphris, M.D.Brux., F.R.C.P.Edin., D.M.R. and E.Cantab., etc. Oxford Medical Publications, Second edition. London: Humphrey Milford, Oxford University Press. 1925. (Demy 8vo, pp. xvi + 203; 15 figures. 8s. 6d. net.)

⁵ *Facts about Artificial Sunlight*. By Edwin L. Ash, M.D. London: Mills and Boon, Ltd. 1925. (Cr. 8vo, pp. 62. 2s. 6d. net.)

A patient treated himself, fell asleep during exposure to the radiations, and for a time his life was in danger. Such a case is a warning that these rays are of great power; properly used they are invaluable servants, improperly used they are dangerous. There should be at least medical supervision of the dosage and direction before applications are made.

PYORRHOEA.

Dr. B. GOTTLIEB of Vienna has, in a pamphlet recently published, presented a new outlook on pyorrhoea. A literal translation of its title is dirt pyorrhoea, paradental pyorrhoea, and alveolar atrophy.*

Dirt pyorrhoea connotes for him a chronic suppurative marginal gingivitis without pocketing which rapidly clears up under treatment; paradental pyorrhoea implies suppuration from these pockets, and is to be diagnosed only when, in spite of appropriate treatment, suppuration persists; alveolar atrophy occurs in two forms—atrophy of the alveolar edge, and a diffuse atrophy of the alveolar bone—the chief symptoms being loosening and migration of the teeth. Atrophy of the alveolar edge is generally an accompaniment of dirt pyorrhoea, while paradental pyorrhoea is bound up with diffuse atrophy. With the first of these combinations pocketing and discharge of pus are early symptoms; while in the second migration and loosening are the early symptoms, pocketing and pus appearing only late in the disease. As a general etiological groundwork the author puts forward a theory of progressive eruption of the teeth, according to which the attachment of gum to tooth is slowly but persistently moving towards the apex of the root, while at the same time the alveolar edge atrophies. Disharmony in this process leads to pocketing. He appears to hold that diffuse atrophy depends on an inherent or acquired inability of the bone to withstand the mechanical demands of mastication. Two kinds of mouths are to be distinguished—those capable and those incapable of reaction to use. In the first class cement hypoplasia leads to even firmer implantation, while in the second the periodontal space is widened and the teeth loosened. Treatment centres round the replacement of every lost tooth by bridge work and the establishment of a flat articulation, both measures being intended to secure a general distribution of the stresses of mastication. The internal administration of arsenic is recommended on the ground that arsenic excites the growth of bone. Local cleanliness is insisted on, and if this fails to cure the disease the inference is, not that the cleaning was insufficient, but that the disease was independent of local sepsis. Here, in fact, lies one of the weak points of the argument. Nor will the idea of continuous eruption meet with general acceptance. There are too many elderly people of whom it may be said, as of Moses, *nec dentes illius moti sunt*.

But while we disagree with the author's main contentions, we recommend to all interested in "pyorrhoea" a careful study of his essay. The microphotographs of teeth *in situ* alone will repay the student.

HEREDITY AND CANCER.

DURING the year 1923-24 a series of six lectures were given under the auspices of the Mayo Foundation by authorities on various aspects of heredity and are now published, with a short introduction by Dr. L. B. Wilson, director of the Mayo Foundation for Medical Education and Research, in a book entitled *Our Present Knowledge of Heredity*.⁷ A series of lectures given at the Mayo Foundation and at the Universities of Wisconsin, Minnesota, Nebraska, Iowa, and Washington (St. Louis) is sure to repay study. The first lecture, on the general problem and history of heredity, is appropriately given by a biologist, Professor W. E. Castle of Harvard, and is followed by Professor C. E. McClung of the University of Pennsylvania on the difficult problems of

the heredity of sex. The much-debated question of the inheritance of acquired characters is clearly and impartially set out by Professor John A. Detlefsen of the Wistar Institute, University of Pennsylvania, who in conclusion pleads for an open mind in spite of the lack of convincing evidence for somatic induction.

There are two very interesting lectures on the heredity of cancer; Miss Maud Slye, out of the fullness of fifteen years' experience of breeding mice, maintains that inherited predisposition is essential in determining the appearance of cancer, not only in the individual, but in the organ attacked; she believes that if human cancer statistics, when correctly compiled, were biologically read, they would show, as certainly as do mice statistics, the inheritability of cancer. Professor H. Gideon Wells of Chicago makes it clear how inadequate human statistics are, as compared with the animal observations made by Miss Slye and others; he however, collects a number of examples of family cancer, especially of retinal glioma. With regard to the mechanism of heredity, he notes that Levin, on the basis of his statistical investigation of cancer in man, concluded that resistance to cancer is a dominant character, the absence of which creates the susceptibility to cancer, whereas Davenport, from an analysis of 243 cases, regards the liability to cancer as the dominant factor. This series of attractive lectures, which must appeal in a special way to medical readers, closes with one on eugenics by Professor M. F. Gayer of the University of Wisconsin.

NOTES ON BOOKS.

IN the preface to his book on *Insects and Disease of Man*⁸ Dr. CARROLL FOX states that it is designed "for a student taking up the study of medical entomology" or for the health officer. The latter will certainly find the work useful, for it is of convenient size, and the descriptions of insects in the first part and of preventive measures in the second are interestingly written and, though sufficiently detailed, are not too lengthy. The student, however, will not be able to reap much advantage unless he has previously taken a practical course in the subject. Part I, on medical entomology—a vague term—describes various orders, genera, and species of insects and gives elaborate keys to facilitate their recognition. Most of these descriptions are adequate, an exception being glossina, the account of which is very poor in comparison. We note with surprise that in the bibliography on the subject no mention is made of Professor Alcock's book, which has been for years and still is the constant guide and companion of hundreds of medical officers in the tropics. In Part II we find clearly expressed accounts of the chief species of anopheles, their life-histories and habitats, and anti-malarial measures are interestingly described. *Anopheles punctipennis* is said to be a "proch biter," a term which we have not before met with in scientific literature. Descriptions of the various diseases conveyed by insects are scrappy. In a work directed rather to prevention one must not, perhaps, expect much on this head, but to dispose of the three stages of sleeping sickness in fourteen lines errs on the side of brevity. Among the transmitters of trypanosomiasis *Rhodnius prolixus* receives no mention. Why, in a work on insects, a description of various species of rats finds place and "Diseases other than plague affecting domestic rats," including ehrlichiosis of the liver, hernia, vesicle (*sic*) calculi, and pericardial effusion, we fail to see. It detracts from the value of the book and savours of padding. The work is well produced and the misprints are remarkably few.

Our charwoman informed us with pride on one occasion that her daughter had "learnt all Latin in three weeks." Dr. HUGH C. MULDOON, dean of the school of pharmacy, Duquesne University, Pittsburgh, has now enabled the pharmacist to do the same with the "dog" variety.⁹ In twenty lessons the student may absorb all that is required for a knowledge of pharmaceutical Latin, prescription writing, and interpretation. The course is very thorough, and includes pronunciation, grammar, nomenclature, measures of volume and weight, the writing of prescriptions, and numerous exercises. There is also a Latin-English and an English-Latin vocabulary. The list of abbreviations is most complete: we were particularly fascinated by *ne tr. sin. num.*, which we hope the physician uses in appropriate cases. It means *Ne tradas sine nummo*—in other words, C.O.D.

⁷ *Insects and Disease of Man*. By Carroll Fox, M.D. London: H. K. Lewis and Co., Ltd. 1925. (Med. 8vo, pp. xii + 349; 92 figures, 18s. net.)

⁸ *Lessons in Pharmaceutical Latin and Prescription Writing and Interpretation*. By Hugh C. Muldoon, Ph.G., D.Sc. Second edition, revised. New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd. 1925. (Extra post 8vo, pp. xi + 187. 7s. 6d. net.)

⁹ *Our Present Knowledge of Heredity*. A Series of Lectures given at the Mayo Foundation and the Universities of Wisconsin, Minnesota, Nebraska, Iowa, and Washington (St. Louis). W. B. Saunders Company. 1925. (Po.

The forty-fifth volume of the *Transactions of the Ophthalmological Society of the United Kingdom*¹⁰ is issued in two parts, which are almost entirely devoted to the proceedings of the Convention of English-speaking Ophthalmological Societies last July, of which an account appeared in our issue of July 25th, 1925 (p. 165). Besides information about the constitution of the Ophthalmological Society of the United Kingdom, the volume includes the annual reports of the Midland, North of England, and the Irish Ophthalmological Societies. The various papers are fully illustrated, and the volume provides in particular a valuable record of the important convention held last year.

There is room for a textbook of chemistry for students of pharmacy, and from the title we hoped to find it in BENTLEY and DRIVER'S *Text-Book of Pharmaceutical Chemistry*.¹¹ It proved on examination, however, to be less a treatise on chemistry than a treatise on the chemical technology of materia medica, a class of textbooks already sufficiently provided. It is avowedly prepared to meet the needs of those studying for the Pharmaceutical Society's diplomas, and it seems to have been designed to accomplish the purpose rather by appeal to the exercise of memory than by the development of a good understanding of the subject. Where practical instructions are given the book has the character of a companion to the Pharmacopoeia for those not well versed in chemistry. In this sense it may serve its purpose, but it would appear to be better that the student should approach his work on the Pharmacopoeia with a good foundation in pure chemistry.

¹⁰ *Transactions of the Ophthalmological Society of the United Kingdom*. Vol. xlv, in two parts. London: J. and A. Churchill, 1925. (Demy 8vo: Part I, pp. lxxvii + 441, illustrated; Part II, pp. xlv + 544, illustrated. £2 net the two parts.)

¹¹ *A Text-Book*. J. By Arthur Owen Bentley, Ph.C., and John A.I.C. London: R. Milford, Oxford University, viii + 456; 3 figures. 18s. net.)

PREPARATIONS AND APPLIANCES.

Gas-Oxygen-Ether, etc., Apparatus.

Mr. H. EDMUND G. BOYLE, O.B.E., M.R.C.S., L.R.C.P. (London, W.1), writes: The accompanying illustration depicts the latest improvements in the machine known by my name. The water sight feed for mixing the N₂O and O of the new set of triple bottles is substantially the same as it has always been, but the mounts for the ether and chloroform bottles are worked on a different, and I think an improved, principle. They are also made with twin bottles for those who do not want one for chloroform. In place of the two levers of the older type, one for "on" and "off" and the other for the degree of saturation required, I now have one lever only; this, when moved over a semicircular scale, causes the gases to go either through

a by-pass, or partly through the by-pass and partly into the anaesthetic, or entirely through the anaesthetic as required. By setting the lever to such a position that only a fraction of the gases bubbles out of a small hole drilled near the bottom of the long tube in the anaesthetic bottle, a very lean mixture is obtainable; and on the other hand, even with a full flow and a high pressure, leakage is negligible. This new arrangement of levers enables one to regulate the amount of ether or chloroform with far greater accuracy than was possible formerly. For those who want to use much ether, there is provided a hot-water cup to enclose the ether bottle as a precaution against freezing. The lamp to prevent the gas from freezing,

which was always a source of danger, has been done away with. This has been rendered possible because Messrs. Coxeter are now providing us with non-freezing gas; but in any case I find that a small hot-water bottle placed on the side of the reducing valve of the gas bottle prevents freezing and enables one to get a steady flow of N₂O. I have to acknowledge my great indebtedness to Mr. Wellesley of Coxeter and Son, Ltd., for producing such an effective method of controlling the small amount of ether or chloroform that is used.

Nova et Vetera.

ANCIENT EGYPTIAN PHYSICIANS.

BY

EDITH M. GUEST, M.D., B.S.,

ASSISTANT IN THE EGYPTOLOGY DEPARTMENT, UNIVERSITY COLLEGE, LONDON.

The ancient Egyptian medical writings have been amply put at the disposal of scholars, but very little has been written on the more personal aspect of the physicians of that age and their work. The sources of information are scanty, for all we can do is to gather stray hints from the tomb sculptures or the papyri. All the consecutive information available is that offered by the classical writers, whose date is some thousands of years later than our earliest Egyptian physicians, but even these are enough to show the world-wide respect in which Egyptian medicine was held. We read, for instance, in the *Odyssey*¹ of "the abundant herbs of Egypt, healing and beneficent, used by men more skilled in medicine than any of human kind." Herodotus² tells us that he found in Egypt that all places abounded with physicians, and that their art was divided into distinct parts, each applying himself to the care of one specialty only: some to the cure of the eyes, others to the head, teeth, or abdomen, and so forth. Pliny³ tells us that the physicians were paid from the public treasury, but that in return for this they were forced to study, and were punished if their treatment deviated from the canon. Should a patient die it was a capital offence, but was to be condoned if the physician had applied all the recognized remedies. They might also receive fees, except for patients on a foreign journey or a military expedition.⁴

The chief medical schools were at Sais and Heliopolis, and were in both cases attached to the great local temples. At Sais the ruler is called the *Wr Swnw*, a title meaning "Great One of the physicians," and found as early as the third dynasty (4991-4777 B.C.); he also bears the title Chief Priest of Neith, the goddess of Sais. During the troubled times that preceded the Persian conquest this institution must have fallen into decay, but such was its reputation that Darius sent his body physician to Egypt to re-establish at Sais "The House of Life," and so far as possible to replace all the books and appliances of which it had formerly been possessed. The other great medical school was the temple of the Sun-God at Heliopolis, and its governor also bore a priestly title as well as the medical one, which in this case was "The Great Seer" (*Wr Ma*). This was the "On" at which Moses learnt his medical lore, and of which he became a priest. This school, too, dates back to the early dynasties, and even then had its roll of medical writings at command. One of its early priest-doctors was Hw, whose tomb was found among those of other high priests at Matarije. He is called "the greatest of the Seers," and many hundreds of years later he is recorded in the Ebers medical papyrus as the maker of a famous eye-paint still in high favour.

To discuss what they learnt in the medical schools would be to review the whole subject of Egyptian medicine, which is not the purpose of this paper. They studied the medical papyri, which taught them both diagnosis and treatment, and they must have done some post-mortem work to fit them for their duties afterwards, for, as Pliny tells us,⁵ it was the custom for physicians to examine bodies after death to ascertain the disease of which the person had died. They studied gynaecology (though, judging by the extant prescriptions, this could not have been to much purpose) and midwifery, but the actual obstetrical work seems to have been done by women. They did little surgery and less dentistry, but they perhaps learnt to place themselves in a kindly relation to their patients such as no doubt helped to win them the high honour and esteem in which they were held. Thus we find depicted⁶ a circumcision operation in the Old Kingdom, in which the operator soothes his patient by murmuring "I will make it pleasant." It is worth noticing that he uses a very clumsy knife,

apparently of flint, indicating a ritual aspect of the act. Another wall-relief shows us an operation in progress which requires the holding down of the patient's arms.⁸ Clearly it is very painful, but the kindly surgeon remarks, "I will make it pleasant, my dear." Another patient to whose foot something is being done begs: "Do not let it hurt me"; to which the surgeon replies: "I will do it so that thou praisest it, O King." As he is not operating on a royal person, this epithet seems to be a very human touch—a little sarcasm, in fact, as who should say "Who are you to dictate to the doctor?" As might be inferred from their priestly titles, these physicians had priestly duties as well. An Wab-priest who is also Swnw is recorded in the Ramesseum⁷ as pronouncing on the purity of the sacrificial victims. The same duty was performed in the Middle Kingdom by a priest of the goddess Sekhmet.⁸ The priests of Sekhmet were regarded as specially skilled in medicine, perhaps on account of the connexion between the medical demigod Imhotep and Sekhmet, who is sometimes regarded as his mother. Embalming was not among their regular duties, but in a bilingual inscription of Ptolemaic time an embalmer is termed "syn," which is doubtless identical with "swnw."

Public health was not neglected. Herodotus notes with wonder that the Egyptians had latrines within the house, not outside like the rest of the world, and this must have involved some system of removing refuse. A study of titles occurring on the steles throws not a little light on this subject.⁹ A Middle Kingdom stele commemorates one Senebef, whose title is "Mer per n wda," which means "Superintendent of the House of Health." Another personage is "Palace Superintendent of the Fumigation." This last word is not quite certain, as it is represented by a sign otherwise unknown, but since this has the form of a pot resembling those associated with incense, but not quite identical, the translation "fumigation" seems obvious. Another official is "Rekht n senneter m aba resy"—that is, "he who understands incense in the palace of the South." This last is a very old title, dating from the time of the immediate successors of the builders of the great pyramids. There were also similar methods for keeping the temples healthy, for a stele of about the same date records a "Her seshta senbet m Per Dhwtj," or "Overseer of the Secrets of Health in the House of Thoth"; and yet another official is "Palace Overseer of the health fumigation in the House of Thoth." Some of these intendants or overseers carry a title "Schd." This word means to make bright or clear, and we may perhaps render it "consultant"; it implies that they have a regular staff of health officials under them. We find, for instance, a Palace Consultant of fumigation, and a secretary or scribe of the same department. The Egyptians were indefatigable organizers, and had overseers, scribes, experts, and other officials in overflowing numbers in every department of the State. It is not surprising, therefore, to find that the medical profession was organized even apart from the public health service. In the time of the pyramid builders (fourth dynasty) we find a Mer Swnw, or Chief of the Physicians, and a Per Aa schd Swnw, or Palace Consultant Physician. In the Middle Kingdom there was a Palace Great Physician (Per Aa Wr Swnw) and Palace Consultant Physician, titles which recur in the twenty-sixth dynasty, nearly two thousand years later.¹⁰ Indeed, they seem even to have gone so far as to organize a pharmacological department, for we find a Mer Shena, or "Superintendent of Medicine," and a "Superintendent of the office of the measures of medicine." Nay, we seem to find a foreshadowing of club or insurance practice in the title of one of the personages of the fourth dynasty, "Swnw shet se-w," which means "Physician of the lake men." Perhaps for the lake men an expert in malaria was needed, or the reference may be to a gang working near the lakes. In the Middle Kingdom we discover a "Swnw Sa-w," a "sa" being a gang or guard. One of the organized classes in ancient Egypt was that of the magicians, a highly reputable body, for there was a magician to the king. Egyptian medicine never quite shakes off the association with magic, and in the Middle Kingdom they must have been closely allied. Hence we

find two nobles whose titles run: "Great Physician," and "Chief of the Magicians."

In spite of what Herodotus said, there is little in the titles to indicate special branches of practice. In the third dynasty we read of an "Wr lw swnw," which means Great one of flesh doctoring, and may have reference to surgery; and the title occurs off and on up to the twenty-sixth dynasty, a range of over three thousand years. In spite of the obvious attention paid to the eyes and the large number of prescriptions for them in the medical papyri, there is only one definite mention of an oculist: it is one Ypy, who is called "Palace Consultant of making to see" (Per Aa schd Ma), and he dates from the Old Kingdom. As we have already noted, the title Schd suggests the presence of a body of practitioners under him.

Of the men themselves who carried out these numerous activities we know very little indeed. For the most part all we can gain is a hint from the funeral steles that bear their names or from some story handed down on papyri of a character little connected with medicine. But the very fact that they have such steles and bear the imposing array of titles that they do, proves clearly that their professional rewards were high, unless, indeed, we are to infer that the multiplication of offices borne by them excluded a whole-time devotion to their art. The latter alternative is suggested in the case of the very earliest named Swnw, who is none other than the great Ra-hesry, of the third dynasty, well known to us from his portrait on the exquisitely carved wooden panel found in his tomb. He held more than a dozen high offices of State, and was clearly a man of great wealth and importance.

In the fifth dynasty King Sahura had a chief physician called Sekhmet-n-anub, whose stele is in the Cairo Museum.¹¹ His tomb was found at Saqqara, and from it we may infer that he did not find his profession very lucrative, for it is a poor tomb compared with those around it. It has, however, a very fine false door, which, as we learn from the inscription, was presented by the king. Almost we are tempted to regard it as a tardy reparation for that apparently age-long failing, a want of promptitude in the payment of the doctor's bills. The reign of Nefer-ar-ka-Ra (about 4452-4432 B.C.) presents a little more medical incident. In a tomb at Abusir¹² it is recorded that the king came to visit a certain building, when one Wsekh Ptah fell down apparently dead. "His Majesty saw him that he heard not." Then the solicitous king, determined to leave no stone unturned, sent for "the royal children, companions, kher-heb priests, and chief physicians," who came as commanded with "a ease of writings." But it was too late: "They said to His Majesty that he was lost." The king provided an ebony coffin. The names of many other physicians have been found and recorded by Sir Flinders Petrie,¹³ but for the most part they are merely names so far as their professional aspect is concerned. Coming now to the eighteenth dynasty, we learn that Amenhotep III (1414-1379 B.C.) was accompanied on all his journeys by his physician. Again, very much later, we find Apries (589-570 B.C.), and Amasis (570-526 B.C.) with a physician, Pefnefdineith, who was evidently held in great honour, for his titulary runs: "Sole companion, Chief of the palace, Overseer of the Gold Treasury . . . Local Governor of Dep, Prophet of Horus of Pe." He ruled and restored Abydos, and was evidently quite a man of business, for he says, "I restored the house of the sacred writings. . . I recorded the offerings of Osiris. I put in order his contracts."¹⁴

But it was not on any of these that the fancy of Hellenistic Egypt fixed itself, to make of him an "Egyptian Aesculapius," but, oddly enough, on an individual whose claim to be either a demigod or a physician is both late and dubious. Their choice fell upon one Imhotep, whom they called Imouthes, a man whom the Egyptians of earlier time had apparently held in high honour for his learning and perhaps his magic, for this seems to be the bearing of the few references to Imhotep that occur in the Middle and New Kingdoms. In the "Song for the House of Intef," which was probably written in the era of the Middle Kingdom, though it

comes down to us in a New Kingdom MS.,¹⁵ the poet writes: "I have heard the words of Imhotep and Herdedef: men speak much of them still. But where are their places? The walls are fallen, they have no places more, they are as if they had never been." Now these are not the terms in which a god or a demigod would be spoken of, and this Herdedef with whom Imhotep is coupled was a son of Khufu, the builder of the Great Pyramid, and never had any claim to be regarded otherwise than as a man. In the New Kingdom it is clear that Imhotep was held in great reverence as a man of learning, for a funeral stele¹⁶ of one Amenhotep who lived in the time of Amenhotep III (1414-1379 B.C.) reads thus: "May the Wab-Priests stretch forth for thee their hand with water upon the ground, like that which is done for Imhotep, from the end of the water bowl." Again, Imhotep is regarded, not as a god, but rather as the scribes' spiritual ancestor, for ever to be had in remembrance by this ceremony.

Statuettes of Imhotep are many, but they carry no insignia of godhead before Graeco-Roman times. He is generally represented as seated, with the garments and shaven head of the priest, and in his hand a papyrus roll. Not till Hellenistic times does he carry the ankh (the *crux ansata*), which is the sign of godhead, and even then there is no indication on any of these statuettes that he was a physician. In Ptolemaic times his cult as a demigod rose to its full height, and he was regarded as a personage of superhuman learning and as a great temple architect, the founder of the temple of Edfu. He had a temple near Memphis, and long inscriptions are written about him in the Ptolemaic temples of Edfu and Philae, and are added to the walls of the older temple of Deir-el-Bahri. He is addressed as both god and man. His titles are those of a priest and of a learned man: "rekh khet," which means "knowing things." A manuscript of the period tells how King Zeser of the third dynasty appealed to Imhotep in a year of famine, begging him to reveal how the gods of the Nile could be propitiated and the famine stopped. The information was supplied and prosperity restored to the land. It is here that we find developed a new feature of his career as a god, for he is credited with a divine father, the god Ptah. Later he seems to have been regarded as the son of Sekhmet the goddess, and so takes his place in the divine triad of Memphis—Ptah, Sekhmet, and Imhotep. At an earlier stage he was given a human mother, one Kheredu-ankh, who, as the cult of Imhotep became more firmly established, was entitled a "Mother of the God," while his sister-wife became "Sister of the God," both retaining the human titles proper to the great ladies of the period. But as yet there was no word of his being a physician. In the time of Cleopatra and Caesarion he appears to be accumulating medical attributes, though still they are little more than magical. A dream of the High Priest P-sher-n-Ptah¹⁷ records that Imhotep appeared to him and spoke thus: "Let a great building be made in the holy place of Ankh Tawi (Memphis) at the place where my body is concealed. I will give thee for it the reward of a son."

Not before the Hermetic writings, which Professor Petrie believes date from the time of Darius, but most other scholars place in the first century or two of the Christian era, does Imhotep appear unmistakably as a physician. In the "Asklepios" Hermes is discussing demigods, and mentions, as an example, "Imonthes the first discoverer of the healing art," who "has his temple in the Libyan mountains in the neighbourhood of the banks of the Crocodile [that is, the Nile], in which his earthly part, that is, his body, lies, while the other better part of him . . . has gone back to heaven, where he yet lends all help to weak men, which he used to afford them through his medical art." By this time his temple near the Serapeum at Memphis is called an Asklepeion, and there is some slight evidence that cure by incubation was practised there. This, and his now complete assimilation to Aesculapius, are implied in one of the Oxyrhynchus papyri dating from the second century A.D.¹⁸ which is headed "Praise of Imouthes Asclepius." Here he is called both Imouthes, son of Ptah, and Asclepius, son of Hephaestus. The record states that a roll of his writings was found apparently in his temple at Memphis in the time of the Pharaoh

Neetanebo, who was so struck with its divine qualities and with the antiquity of his worship, which he traced back to Menkaure, the builder of the third pyramid of Gizeh, that he presented to the god 330 acres of cornland and made other gifts to his priests. We are unfortunately told nothing of the contents of the roll, for the writer of the record delayed translating it for three years because he thought it unfitting to write for men the mighty deeds of the gods. But then Imhotep appeared to him in a dream and cured him of fever, at the same time bidding him write the book, saying: "Every Greek tongue will tell thy story and every Greek man will worship the son of Ptah, Imouthes. Mencheres . . . presented to the tombs of Asclepius son of Hephaestus, Horns son of Hermes and Calcoibis son of Apollo, money in abundance . . . The manner in which the god Asclepius bade Mencheres busy himself with his tomb . . ." Here, unfortunately, the papyrus breaks off.

Amid this vague mass of evidence, can we discover who Imhotep really was? Late evidence regarding early persons and things is to be accepted with the greatest caution, but certain strains deserve credence from the fact that they run consistently through all. There can be no doubt that Imhotep was a man of great learning, whose wisdom impressed itself on all generations from the pyramid age to the Christian era. A late and corrupt manuscript seems to attribute to him great fame as a builder at the beginning of the epoch of mighty stone-working to which the pyramids belong. If this is to be so interpreted, Imhotep may well have been King Zeser's architect and the builder of the Step Pyramid of Saggara. On the stele of the High Priest Khnum-ib-re, in the reign of Darius, he is entitled "Intendant of the workmen of King Zeser." This title "Intendant of the workmen" is one regularly applied to the great architects, such as Sennut, who built the temple of Deir-el-Bahri under Queen Hatshepsut, and if indicates a position analogous to that of a high official of our Board of Works. When Ptolemy, many centuries later, credited Imhotep with the foundation of the temple of Edfu, we know that he was wrong as to the fact, but he was right in echoing the fame of a great architect of long before.

There is a Middle Kingdom composition, called now the Westcar Papyrus, which tells some tales of the wonders that happened at the Court of Khufu, the builder of the Great Pyramid of Gizeh. Here are allusions to the deeds of magic performed by a certain Kher-heb-heri-da-da, as the priestly title runs, within the king's own lifetime. Now this is one of the titles of Imhotep as the steles tell us, and if he were truly a wise man of the time of King Zeser this magician may well have been none other than he. God, physician, man of learning, and magician, it was as the last that his fame lived longest, for we can trace him as an astrologer right through the Hermetic books and up into the third century A.D., when the alchemist Zosimus entitled one of his books "Imonth."

1 CHRONOLOGICAL NOTE.

The dating followed in this paper is that of the "Longer Chronology." Some scholars prefer a "Shorter Chronology" which places every date previous to the early eighteenth dynasty one Sothis Cycle—that is, 1,460 years—later. A summary of the principal epochs of Egyptian history is as follows:

OLD KINGDOM: Dynasties IV to VI, 5546-4077 B.C.
Dynasties VII to X, 4077-3733 B.C.

MIDDLE KINGDOM: Dynasties XI and XII, 3733-3368 B.C.
Dynasties XIII to XVII, 3368-1587 B.C.

NEW KINGDOM: Begins with the eighteenth dynasty, 1587 B.C. It is followed after about four hundred years by a period of confusion and decline, culminating in the conquest by Assyria in 670 B.C., by Persia in 525 B.C., by Alexander in 332 B.C., and by Rome in 30 B.C.

British Medical Journal.

SATURDAY, APRIL 17TH, 1926.

THE ETIOLOGY OF ACCIDENTAL HAEMORRHAGE.

THE progress of ante-natal supervision as a fruitful branch of preventive medicine is being slowly appreciated by the medical profession and the public. Any tardiness in its recognition and adoption in practice is probably due to the fact that, outside hospital reports, its triumphs are seen in individual cases rather than in the mass. Steadily, however, the number of the complications and accidents of pregnancy and labour that may be called preventable is increasing. Under adequate ante-natal care eclampsia, for example, can already be regarded as almost wholly preventable, and the great majority of the complications of labour can now be foreseen, and either averted or treated with every expectation of success. To be forewarned in regard to such matters is indeed to be forearmed. Recent experimental work upon "accidental haemorrhage" by Dr. F. J. Browne, of which we publish a preliminary account at page 683, suggests that this serious and baffling complication may also soon be brought within this hopeful category.

It has long been known that accident or injury was but rarely the cause of the premature separation of the normally situated placenta which results in "accidental haemorrhage." The terminology, which dates from the days of Rigby in 1776, is admittedly unfortunate, and is only to be read in the sense that there is no anatomical reason why separation and haemorrhage should occur. In other words, the term "accidental" is merely in contrast to the "inevitable" haemorrhage of placenta praevia. The only clue to the real nature of accidental haemorrhage which we have had is the curious and persistent frequency with which the more serious cases are associated with albuminuria, and sometimes, especially in concealed haemorrhages, with other and more profound symptoms of toxæmia, including even eclampsia itself. The generally accepted view, which was well summarized in one of the last papers by the late Dr. Gordon Ley, has been that the toxin, which produces the toxæmic symptoms and manifestations, acts injuriously upon the capillary walls in the uterine wall and decidua; and that the consequent retroplacental haemorrhage causes the placental separation. Young, on the other hand, has interpreted matters in the light of his placental theory of eclampsia, and regards the toxæmic symptoms and changes as secondary to the placental separation, and due to toxins produced by autolysis in the detached and dying portion of the placenta.

Dr. Browne's research was an attempt to produce accidental haemorrhage experimentally in rabbits by the introduction of toxins. Several most interesting points emerge from his observations. In the first place, he found that nephritis, either chronic or acute, is probably an important, possibly an essential, factor in the production of the haemorrhage. Secondly, the toxins most successfully employed were organismal in nature, the coliform organisms being found to be the most potent. But Browne found that the mere intro-

duction of the organisms failed to produce accidental haemorrhage unless a chronic or acute nephritis had previously been induced in the animal by the repeated injection of oxalates. In all of six animals so treated injection of the organisms on or about the twentieth day of pregnancy (a period corresponding to the end of the sixth month in human gestation) was followed by accidental haemorrhage, by the abortion of dead foetuses, and by the production in some instances of infarction of the placenta and haemorrhagic effusions into the muscular wall of the uterus. The research is not yet complete, but it is strikingly significant that almost the whole gamut of changes associated with serious accidental haemorrhage in a woman should thus have been produced experimentally.

Basing his views upon these experimental results and upon the known clinical phenomena, the author puts forward the thesis that external accidental haemorrhage, concealed haemorrhage, retroplacental haematoma, and placental infarction, are a pathological unity with a common underlying cause. The occurrence of accidental haemorrhage in the human being in the absence of albuminuria Browne endeavours to explain by the statement, also apparently borne out by his experiments, that a considerable degree of kidney damage, as evidenced by a high blood urea reading, may exist without albuminuria. If, for the sake of argument, we assume the correctness of the author's thesis, several interesting speculations present themselves. Is it possible, for example, that eclampsia, which is so frequently associated with the presence of placental infarction, may be due to the same cause as accidental haemorrhage? Eclampsia is predominantly a complication of primigravidity, accidental haemorrhage of multiparity. Is there some factor present in that difference which determines the different effects of a possibly single cause? Again, if the toxin is organismal, what is the source of the organisms? Is it the bowel or the mouth? These are only some of the profoundly interesting and important speculations which this brilliant piece of research work, even in its early phase, suggests to the mind. Obstetricians will watch with interest its further development.

THE ADMINISTRATION OF HEALTH SERVICES.

At its meeting last week the Council of the British Medical Association took action with regard to four matters of health administration which certainly ought to be related to one another, and the separation of which perhaps requires some explanation. It appointed a special committee to deal with questions of the extension of the scope of medical benefit arising out of the Report of the Royal Commission on National Health Insurance; it completed the personnel of a special committee on suggested Poor Law reforms; it approved a recommendation as to the central and local bodies which should administer a medical service of occupational hygiene, including the present factory medical service; and it adopted the Memorandum of Evidence to be given before the Royal Commission on Local Government Areas which was published in the SUPPLEMENT of January 30th, 1926 (p. 36). In support of this oral evidence will be given by Dr. Brackenbury at an early date. All these matters are, at any rate in some of their aspects, concerned with the complete unification of the administration, centrally and locally, of all health services, which is the declared aim of the Association's policy. They have to be

dealt with separately, nevertheless, because they have been referred by the Government to separate bodies or departments. Two Royal Commissions and two Ministries are concerned. Each of the Commissions has been embarrassed by the fact that part of the subject which it had to review has been included in the reference to the other, or does not specifically come within its reference at all; and the Royal Commission on Local Government has actually postponed the taking of certain evidence until it can be made further acquainted with the result of conversations and negotiations at present taking place with regard to Poor Law administration. The British Medical Association is one of the bodies which has been asked to represent its views on the health aspect of this last subject, and this will be the immediate task of the special committee set up.

The other special committee with regard to extensions of scope of medical benefit was considered necessary both by the Council and by the Insurance Acts Committee because, though the matter is technically within the powers of the Insurance Acts Committee, it was felt that there should be a substantial representation of consultants, laboratory workers, and others who would be vitally affected by any arrangement entered into to bring them within the ambit of the National Health Insurance scheme. As now constituted this special committee seems admirably fitted to advise the profession on this very important matter. There are a sufficient number of members common to both these special committees to keep them in touch with one another.

THE "JOURNAL OF NEUROLOGY AND PSYCHOPATHOLOGY."

THE Council of the British Medical Association, at its meeting last week, decided, on the advice of the Journal Committee, to publish the *Journal of Neurology and Psychopathology* as and from the issue of May, 1926. This journal has been in existence since 1920, and was started to take the place of the former *Review of Neurology and Psychiatry*, edited by the late Dr. Alexander Bruce of Edinburgh, which ran with success from 1903 to 1918. Its aim has been to supply, in the form of abstracts and critical reviews, up-to-date information in reference to the whole field of neurology and psychopathology. A major part of each issue, therefore, is entirely taken up with such abstracts from current literature. It is felt that there is a definite need for as complete a summary as possible of the extensive literature dealing with neurology and psychiatry, and it is hoped that by aiming to supply this need the *Journal of Neurology and Psychopathology* will occupy a supplementary position in relation to other publications in English dealing with these two subjects.

Each number includes also short original articles, and in this section an endeavour is made to extend its usefulness by including contributions from foreign as well as British neurologists and psychiatrists. Thus recent issues contain articles by Professors Brouwer and Zeeman of the University of Amsterdam, Professor Ksawery Lewkowicz of Cracow University, Dr. C. E. Reynolds of Los Angeles, Cal., and Drs. George Hall, Laurence H. Mayers, and J. A. Kerr of Chicago. The original articles during the last year have covered a wide range, and dealt with the following subjects: epilepsy as a symptom of disseminated sclerosis; multiple neurofibromata; syringomyelia in association with epilepsy; organic spinal hemianaesthesia; the

operative treatment of gastric crises; myotonia atrophica; diabetes insipidus as a sequel to epidemic encephalitis; the clinical features of scorbutic neuritis; psycho-analysis and psychotic patients; experimental investigations concerning the projection of the retina on the primary optic centres in apes; the psychopathology of lying; meningococcal meningitis; the colloidal benzoin curve in the cerebro-spinal fluid. In addition to the above a section is devoted to short notes on cases of clinical interest. At the inception of the journal it was decided to include in each issue an editorial article dealing with topics of general neurological or psychiatric interest. The following list of the titles of some of these editorial articles may serve to indicate their scope, purpose, and character: cerebral localization of function; social work in psychiatry; subjectivity and objectivity; neurological therapeutics; the value of human evidence; the nature of desire; philosophy and medicine; cortical functions in relation to neuroses.

The general aim of the journal was indicated in an editorial article in the first issue dealing with the present position of psychopathology. It was pointed out that there was a great need for co-ordination in the work of the different schools of psychopathology, which had not yet achieved a solid foundation of universally accepted principles, so that the common ground may be clearly marked out and the divergences accurately defined; and that a further need was for co-ordination between the findings of psychopathology and the facts which have been elicited by other branches of medicine, notably neurology and endocrinology. It was furthermore stated that one of the chief objects of the journal was to help in this co-ordination and correlation, and the hope was expressed that by presenting a review of the work which is being carried out by the various schools the linking together of the different lines of attack would be facilitated, and that it would be found possible to attain to that comprehensive and catholic view which is indispensable to progress.

The problems of nervous and mental disease with which this periodical deals are probably the most obscure and difficult to solve in the whole realm of medicine; they are of the greatest importance, however, and concern, not only the neurologist and psychiatrist, but also the general practitioner, who is called upon to deal with and diagnose morbid nervous and mental conditions in their earliest stages. For such reasons it is hoped that the journal will meet a real need, and find, under the auspices of the British Medical Association, an increasing sphere of usefulness. Dr. S. A. Kinnier Wilson is the chief editor, and he is assisted by a committee consisting of well known neurologists and psychiatrists. The *Journal of Neurology and Psychopathology* appears four times a year. The annual subscription is 30s. post free (single numbers 8s. 6d. net). Orders should be sent to the Financial Secretary, British Medical Association, Tavistock Square, London, W.C.1.

THE ASSOCIATION'S HOUSE IN THE STRAND.

THE Council of the British Medical Association, at its ordinary meeting last week, was informed of the preliminary steps taken in the sale of the Association's valuable freehold property at 429, Strand. The recently vacated house is proposed to be acquired by the New Zealand Government, and further particulars will be published on completion of the transaction. A brief note of the Chairman's statement is published in the report of the proceedings of Council (SUPPLEMENT, p. 124).

THE NATIONAL PHYSICAL LABORATORY.

THE report of the National Physical Laboratory for the year 1925¹ describes quite a bewildering number of investigations. In many of these researches a goal or even a resting point which permits definite conclusions to be stated may take years to reach, and the phrase "to be continued" has to be written as frequently as in a serial story, and, again as in a serial story, at an exciting stage. One gets an impression of hundreds of workers at Teddington occupied in a dozen different departments or divisions on investigations at first sight disconnected, often running off at tangents, and very generally ending for the time being in a confession of incompleteness; yet it cannot be doubted that to the next generation of scientific workers these labours will appear of extraordinary value, carried out, as they have been, during the most expansive years that science—or physics at all events—has ever passed through. The first function of the National Physical Laboratory, however, is not original research, but testing, measurement, and the determination of constants. It exists to apply the yard measure, so to speak, to the scientific work proceeding in Government departments, research associations, and industrial firms, to relate it with work in other countries, and to set up standards without which progress would be impossible. Hundreds of thousands of instruments of one kind or another, from photographic lenses to tuning-forks, and from sextants to vacuum pumps, are tested at the laboratory in the year. During 1925 the number of clinical thermometers tested was about 600,000. In thermometry, by the way, proposals are shaping for an international scale of temperature, and it is hoped to lay something definite with regard to such a scale before the International Commission on Weights and Measures in 1927. Another international matter which it is hoped shortly to resolve is the precise relation between the kilogram and the pound. In volumetric glassware the "millilitre" has now been very generally substituted as the unit of volume for the "cubic centimetre"; almost the whole of such ware submitted to the laboratory for testing in 1925 was graduated in terms of the millilitre. Among other instruments tested were sphygmomanometers, and it is remarked that those of the mercurial type are now more robust than those submitted in previous years, and they have the advantage of greater accuracy over the aneroid type of instrument, but lack its compactness and its convenience in reading. During the year under review sixty-one radium preparations were tested—a decrease on previous figures, possibly due to the facilities available for radium testing in Belgium, where the great bulk of the world's radium is now produced. Hitherto measurements of radium tubes at the laboratory have only been made after an interval sufficient to ensure that the tubes have reached equilibrium—that is to say, a period of about five weeks; but arrangements have now been made for using speedier methods, and radium preparations may be tested in a period of a few days, though the accuracy is only about half that of the standard test. A radium safe with lead walls two inches thick has been installed at the laboratory; the tables where the radium under test is manipulated also afford a protection of one inch of lead, and the observer when using the electroscopist sits behind a lead screen about half an inch thick. Twenty-two x-ray installations have been examined during the year, and reports have now been made on the x-ray departments of some seventy hospitals and institutions. Although the conditions as to protection still leave much to be desired, a general improvement can be discerned as a result of the recommendations of the X-Ray and Radium Protection Committee (formed in 1920 under the chairmanship

of Sir Humphry Rolleston), at whose instance the inspections have been carried out. A number of sections of floors, walls, and ceilings for proposed x-ray departments have been examined at the laboratory. It is pointed out that barium plaster, which is often used as a wall covering, diminishes in protective value when an installation of the higher potentials (200 kilovolts) is put in. The plaster is not always uniformly mixed, and the report urges that more care should be taken to eliminate lighter patches, and that a good margin of safety should be allowed in the thickness of walls so covered. Much other investigation is proceeding on x rays, especially from the point of view of their use in metallurgy. The programme of work for the present year includes the design of an apparatus for the practical realization of a unit of x-ray intensity, also a study of the relations between x-ray and cathode-ray energy. Some useful work has been done on the acoustics of buildings, and the effect of galleries, partitions, and simple obstacles in the transmission of sound in auditoriums is being studied. At the request of H.M. Office of Works some tests on illumination have been carried out to determine the minimum daylight factor which may be considered necessary for clerical work. Work has also been undertaken for the Food Investigation Board with the object of finding out the thermo-physical properties of various refrigerating liquids, and of constructing an apparatus for measuring the heat evolved in the respiration process of fruit. Optical glass has received attention, and an endeavour has been made to detect the changes, if any, which occur with ageing. Other work relates to dental alloys and amalgams; the study of the constitution of the binary alloys of silver and tin has been carried to completion, and a report has been submitted to the Dental Investigation Committee of the Department of Scientific and Industrial Research. Other subjects under investigation are the measurement and control of humidity, the brightness of diffusive glass illumination fittings, and the investigation of impurities in chemicals; this leaves out of account a whole realm of subjects of principal interest to the metallurgist and the mechanical and electrical engineer.

THE OPTICAL CONVENTION.

THE Prime Minister, in opening the Optical Convention at South Kensington on Monday morning, declared that the average man was a stranger to the whole apparatus of optical science except for such interest as he might have in playing with a hand camera. Yet optical science is a necessity of civilization, and Mr. Baldwin instanced particularly the essential part played by the microscope in the war against disease, and said that in this field, as in others, there remained large possibilities still untouched. The Convention will help to popularize optics, for though it is true that the hundred papers, arranged in two sections, are mostly on recondite subjects, such as the measurement of refractive indices or the expansion coefficients of optical glasses, the exhibition, which fills three halls and several smaller rooms in the Imperial College of Science and Technology, has many attractions. For one thing, there is an entertainment section, where all the old optical illusions are forthcoming in new guises—the distorting mirrors, the devices for magnification and minification, and so forth. Here the visitor can lose his head, and watch as an interested spectator his own decapitation. Then there is an historical section in which Newton's experiments are repeated, and an historical collection of optical, especially astronomical, apparatus, and of some ancient books and catalogues. Contrasted with all this is an exhibition of what is being done in the present day in the way of experiment and research in optics—a display to which the National Physical Laboratory and the technical optics

¹ Published by H.M. Stationery Office for the Department of Scientific and Industrial Research. 8s. 6d. net.

departments of certain colleges and polytechnics have made some valuable contributions. Again, the present position of the British optical industry is illustrated by the trade exhibits of nearly a hundred firms. One thing brought home to the visitor here is the energy with which optical glass production has been pursued in recent years in this country. Three firms now produce optical glass whereas only one produced it before the war, and whereas the catalogue of that one firm in 1914 listed only 26 types of optical glass its catalogue to-day has a range of 112 varieties. The latest models of the ophthalmoscope, the retinoscope, the keratometer, and the perimetre are on view. The optical lanterns, polariscopes, polarimeters, and microscopes, with all kinds of accessories, are on view in great numbers, and the microscopes include the complete ultra-violet apparatus made for Mr. Barnard and Dr. Gyo for examining the filter-passing virus. Attention is drawn, in other exhibits, to the importance of industrial photometry, as in the measurement of the total light output of electric lamps, the design of efficient lighting systems from the point of view of proper illumination, and the usefulness of "artificial daylight" in a number of directions, including medicine and dentistry. Two new industrial applications of optics may be mentioned. One of these is the introduction of a third colour into railway signalling. The red light hitherto has served a double purpose—a "warning" on the distant signal and a "stop" on the home signal. Work has been proceeding on a moderately deep orange light to take the place of the distant signal, and this is now being tried on the London and North-Eastern Railway. The orange is distinguishable equally from red and green, and is not to be confused with any stray white or yellowish light which might be seen from the footplate. Moreover, in foggy weather the colour tends to approach the appearance of the red signal. The other development has to do with the problem of eliminating glare or dazzle from motor car headlights. Two recent solutions are offered. One of these is based on the plan of obscuring a part of the lamp bulb with a diffusing yellow coat. The other involves the use of two filaments which can be switched on at will, the one producing a powerful driving beam, and the other a dispersed beam for use at the moment when the oncoming car is close at hand. Ophthalmic optics, of course, is the subject of several of the papers, and sight-testing apparatus and eyeglasses of every kind are shown in the exhibition, including invisibly fused bifocals and trifocals. In the matter of spectacle-making the thing that may strike the visitor is the multiplicity of fashions in "eye-wear." A pair of old-fashioned steel spectacles is hard to find. So-called "tortoise-shell" (real turtle and mock turtle shell), gold, platinum, and rustless alloys are the materials of the modern fitting. Not only so, but if the lenses are to be varied for different uses, it seems to be of almost equal importance that the fittings should be varied also in harmony with the occasion. A certain form of frameless spectacle is recommended for business calls, the comfortable and dignified tortoise-shell for the office, and a pair of gold-rimmed pince-nez for the dinner-table; while ladies have lorgnettes for shopping and the theatre, another kind of eyeglass for evening wear, and still another for driving and sports. The Convention did not begin its general meetings until Tuesday, and we hope next week to give some account of the more noteworthy events in its programme.

THE FLOW OF BILE.

BILE is secreted continuously into the hepatic ducts and passes into the common duct under a pressure of 60 to 70 mm. of bile. But its further progress towards the duodenum is checked by the sphincter which guards the exit from the common duct, for this sphincter, Winkelstein

and Aschner¹ have shown, offers a resistance equivalent to 120 to 130 mm. of saline. Therefore the bile flows into the gall bladder, the current being favoured by the reduced intra-abdominal pressure during expiration. During inspiration the increased pressure in the abdominal cavity forbids the entrance of bile into the gall bladder, and during this phase bile can be expelled through the cystic duct into the common bile duct, and Winkelstein and Aschner think that a little may even be forced past the sphincter into the duodenum. They found that when the sphincter of Oddi was kept patent by means of a small glass cannula the gall bladder did not fill but remained collapsed, all the bile flowing directly into the duodenum. This sphincter then, like the pylorus, may be regarded as a "keeper of the gate." Its work is more onerous than we have been accustomed to think, for estimates show that almost a litre of bile is produced daily by the liver, and most of this, in concentrated form, must pass at regular intervals into the duodenum. In the fasting state the sphincter remains closed, but opens when the sensitive mucous membrane around its opening is bathed with gastric chyme. Thus, when the papilla of Vater is touched with dilute hydrochloric acid, peptone, dextrose, or fat, the tonus of the sphincter relaxes at once. Pilocarpine injected subcutaneously increases this sphincter's tone, and atropine diminishes it. It is probable that stimulation of the vagus nerve excites the gall-bladder musculature as well as the sphincter, and stimulation of the sympathetic inhibits both. As with other sphincters of the gastro-intestinal tract, it seems likely that here also tonus is never completely lost under normal conditions, and experiment suggests that a pressure of 90 mm. of saline at least is necessary to overcome the sphincter, even when its tonus is decreased by substances acting either locally or through the vegetative nervous system. When the sphincter is not relaxed the usual pressure prevailing in the gall bladder and common bile duct is insufficient to overcome it, though during coughing and vomiting some bile might be squeezed through. Reduced to a single sentence, the conception of Winkelstein and Aschner may be expressed as follows. The sphincter which guards the duodenal opening of the common bile duct holds back the passage of bile during the fasting state, but under the local relaxing influence of the gastric chyme, and probably also reflexly through the vegetative nervous system, the tonus of the sphincter is reduced sufficiently so that the rise of pressure in the gall bladder and common duct during inspiration opens the sphincter, and bile from the gall bladder and liver flows into the duodenum.

IMMUNIZATION AGAINST MEASLES.

THE gratifying results which have followed the introduction of the Schick and Dick tests for diphtheria and scarlet fever respectively, together with the discovery of methods of immunizing patients against these diseases, have given rise to strong hopes that similar success might soon be reported in the case of other infectious conditions. An intensive study of measles in this connexion has been in progress, particularly in the United States and Italy, and in both countries organisms have been isolated which seem to have some etiological significance, though absolute specificity could not be demonstrated. In the *Journal of the American Medical Association* for March 27th (p. 932) a preliminary report is published by Drs. N. S. Ferry and L. W. Fisher on the preparation of a measles toxin and its employment in diagnosis and treatment. The authors state that they have isolated a small Gram-positive aerobic streptococcus in pure culture from the blood of patients in the early stages of the disease. This organism is said by

¹ *Amer. Journ. Med. Sci.*, January, 1926, p. 104-111

the authors to differ from that previously described by Tunncliffe, in that it grows luxuriantly in the presence of oxygen, and produces a soluble toxin specific to measles. In an editorial comment in the same issue of the *Journal of the American Medical Association* (p. 955) it is pointed out, however, that the Tunncliffe organism is aerobic in cultures of the second generation, and that the two organisms are probably identical. Ferry and Fisher, who have distinguished their organism by the name of *Streptococcus morbilli*, state that it appears in pairs and chains. Experiments were made with its toxin on various patients, and it was found that those who had had measles previously did not react to intracutaneous injections. Thirty children were so tested without a single positive result; out of thirty adults with histories of measles, two did, however, react positively. Out of thirty-five tests on patients who had not had measles, fourteen gave positive reactions. Patients in the pre-eruptive and early stages of measles gave positive reactions, while those in the later stages, and especially convalescents, gave negative reactions. When the toxin was mixed with a pooled serum of patients convalescing from measles no positive skin reaction was produced in susceptible persons; this is held to prove that the convalescent serum neutralized the toxin; nor was a positive skin reaction obtained when the toxin was mixed with serum from an animal previously immunized with the toxin. It thus appears that this toxin is capable of stimulating the production of an antitoxin with neutralizing properties. The toxin was not neutralized by being mixed with scarlet fever antitoxin or normal horse serum. Two out of four persons with positive skin reactions were given an injection of convalescent serum, and two days later it was found that these two gave negative reactions, while the two controls were still positive. The serum of an animal immunized by the toxin had the same immunizing or neutralizing properties as the serum of a person naturally immune, indicating the etiological nature of the toxin and of the streptococcus with regard to the disease. Suspensions of the streptococcus were found to be agglutinated by the serum of convalescent patients from measles, and intracutaneous injections into rabbits of live cultures of the organism produced severe local infections surrounded by large areas of hyperaemia, which at times resembled a typical measles rash. Although it is not prudent to draw final conclusions from the relatively small number of experiments, yet there certainly appears to be promise of the establishment of a valuable prophylactic treatment of this widespread infection.

FERMENTED MILK.

NOMADIC tribes in nearly all parts of the world have discovered the trick of fermenting milk, and thereby changing it from an easily decomposable food to a refreshing and often mildly alcoholic beverage. This fermentation has, of course, proved a fruitful field for speculation; its initiation is sometimes attended with ritual; the energizing grains by which the fermentation is evoked are regarded, perhaps, as a special gift from Mohammed or a crumb from the festivities of the gods. Bacteriological analysis has torn aside the veil of mystery which for centuries has surrounded the origin and method of action of these particular fermentations. Nearly all the different types of soured milk are due to the activities of the aciduric group of milk-souring bacteria, sometimes aided by yeasts and coliform bacilli. When other methods of food preservation were discovered the custom of drinking fermented milk fell into abeyance, although, of course, butter and cheese have retained their hold on the affections of all civilized countries. But with a curious persistence and periodicity the fashion of drinking soured milk has

returned again and again, and now we are told that some special benefit can be derived from the soured milk which our progenitors consumed in abundance. It may be worth while to recall that some thirty years ago the fashion of drinking koumiss spread far and wide throughout Europe and, we believe, America, from the steppes of Russia. The milk used by the native tribes was mare's, sometimes camel's, and the fermentation was of a mixed character, so that the finished drink contained a small proportion of alcohol (1 to 2 per cent.) and lactic acid (0.5 to 1.5 per cent.). It had an acid flavour agreeable to some persons, and a slight stimulating action on digestion, which was supposed to be good for pyrexia, chronic pulmonary disease, and various cachectic conditions. In Western Europe it was made from cow's milk—a practice introduced from the Caucasus—and the resultant beverage was called kephir. A little later, if we remember correctly, Metchnikoff promised us the prolongation of life if only we ate enough of the Bulgarian bacillus, but this particular microbe did not long enjoy the confidence of sour-milk devotees. *B. acidophilus*, a first cousin of *B. bulgaricus* (and not easy to distinguish), has now stepped forward to take the leading place amongst the sour-milk microbes. Several books have been written about it; one, *Lactobacillus Acidophilus*,¹ by Nicholas Kopeloff, has started this chain of thoughts. The question which critically minded people are sure to ask after reading this book, or the advertisements respecting *acidophilus* therapy which the postman showers upon us, is whether it has any real value. That is a question which medical experience must decide, but it is well, perhaps, to recollect the two following facts before plunging into *acidophilus* therapy. First, *B. acidophilus* is a normal inhabitant of the human intestine. It is there, for good or ill, within every one of us, and the miracle of transforming the intestinal flora is actually nothing more than the making of this microbe sufficiently numerous for the bacteriologist to be able to distinguish it without too much effort. Secondly, all the laboratory experiments which inspire any confidence show that very large quantities of sour milk must be taken to ensure a transformation to a predominantly acidophilic type. At least a litre of sour milk daily, together with 300 grams of lactose (three quarters of a pound), is necessary for most people, and smaller quantities than this are of doubtful value. This point is emphasized by Dr. Kopeloff in his book. We should draw attention also to the fact that he brings forward evidence to show that nearly all the cultures of *B. acidophilus* sold by commercial firms are absolutely worthless.

STATISTICAL INVESTIGATION OF INDUSTRIAL ACCIDENTS.

THE elucidation of the causes of industrial accidents, with a view to accident prevention, is such an important problem that it has naturally attracted a good deal of attention at the hands of the Industrial Fatigue Research Board. The Board has already published two reports on the subject, and report No. 34, which is entitled "A contribution to the study of the human factor in the causation of accidents," represents a further instalment of its labours. It is due to Miss E. M. Newbold, who was advised in her work by the Statistical Committee of the Medical Research Council. This committee is composed of men who are eminent rather for their knowledge of statistics than for possessing a first-hand knowledge of factory life and conditions, and indeed the report in question is entirely statistical from start to finish. By means of a card system accident data relating to 9,000 men and women were collected for periods of three to twenty-four months at thirteen factories, the factories

¹ *Lactobacillus Acidophilus*. By Nicholas Kopeloff, Ph.D. Baltimore: The Williams and Wilkins Company; London: Baillière, Tindall and Cox. 1925. (Roy. 8vo, pp. xii + 211; 4 plates. 22s. 6d. net.)

chosen being mostly those where machinery and other metal objects were made. This work involves numerous trivial accidents such as cuts to fingers, and altogether the number of accidents tabulated came to over 16,000. The data were subjected to a most laborious and skilful mathematical analysis by Miss Newbold, with a view to elucidating the conclusion—previously arrived at by Greenwood and Woods—that accident liability is due largely to a special personal susceptibility inherent in the individual. As is suggested by the Board itself in the preface to the report, it might be thought that the existence of differences in individual susceptibility is so obvious that it is superfluous to prove it by statistical reasoning. At the same time, it is useful to obtain exact information, for the special susceptibility may possibly prove such an important factor in accident causation as to make it desirable to weed out the susceptible workers, and transfer them to other and less risky jobs. Unfortunately, the nature of the statistical material worked upon by Miss Newbold rendered it impossible for her to obtain this exact information. None of the numerous groups of workers studied by her were homogeneous ones. Usually they represented all the workers in a particular department, such as a motor-car assembling shop or a textile machinery fitting shop. In two instances it is said that the workers were more homogeneous than those of the other groups, but no exact observations were made to prove the point. Hence the only conclusion concerning the excessive accident rate of certain individuals that Miss Newbold felt justified in advancing was to the effect that "there are many indications that some part, at any rate, is due to personal tendency." The investigation of the relationship of accident frequency to age and experience likewise proved rather unsatisfactory. It was found, in confirmation of previous investigators, that accidents decrease both with the age and the experience of the worker; but Miss Newbold found in addition that when an allowance was made for age there was no independent association between experience and accidents—that is, experience did not count at all in accident causation. Information obtained by previous investigators, no less than common sense, indicates that this conclusion is erroneous, and presumably it was due to the character of the statistical data used. These data showed only the length of time for which the workers had been employed at a particular factory or department, and gave nothing of their previous history or experience. One interesting point which was established related to minor sickness, for it was found that a definite positive correlation (+0.3) existed between the number of accidents experienced and the number of visits paid to the ambulance room for sickness. We must, however, agree with the opinion expressed by the Board that, so far as this report is an index, "the limits of knowledge that can be acquired solely by statistical methods have now been reached." For the future reliance must be placed partly on the application of psychological and physiological methods to the study of the individual, and partly on the study of accident data when these are accompanied by detailed observations on the conditions of work under which the accidents were incurred.

INSANITY AND THE LAW.

LORD HEWART, the Lord Chief Justice, was the guest of the Hunterian Society at an informal dinner at Simpson's Restaurant, Cheapside, on April 12th, and after dinner he made a few observations on the criminal law in its relation to insanity. As he was evidently under the impression that no reporters were present, and therefore that for once he did not need to measure his words with the precision which should belong to a published utterance, it would be improper to give any extended report. His observations, and those of Dr. T. B. Hyslop, who followed him, illus-

trated the dissonance between law and medicine in relation to this question. It may be, as Dr. Hyslop suggested, that the medical man has his mind directed to the patient—in this case the criminal—while the mind of the lawyer is occupied with the public safety. Lord Hewart quoted a famous predecessor of his, Sir Matthew Hale, who said, "When I am tempted to pity the criminal I remember also that there is a pity due to my country." One remark of the Lord Chief Justice, based on his thirty years' experience as counsel, law officer, and judge, we may be permitted to quote. He said that the defence of insanity in capital cases—cases in which, on a verdict of guilty, the punishment is death—tended to be put forward almost invariably, whereas in the case of other crimes, such as larceny, housebreaking, forgery, and embezzlement, it was rare to have the defence of insanity ever suggested. But it surely might be replied to the Lord Chief Justice, with all respect, that while one can conceive a "reasonable" motive for these lesser crimes—usually the motive of some immediate gain—few murders belong to this category, being mostly crimes of passion, and that in any case the act of murder is so revolting that it almost points of itself to a disordered mind. Lord Hewart, with his accustomed clearness, laid down what a defence of insanity involves, and we give it in our own words, not in his. In law every person is presumed to be innocent until he is proved to be guilty; but equally every person is presumed to be sane, reasonable, and responsible for his acts until the contrary is proved to the satisfaction of a jury. Therefore it is for the defence to prove insanity, not for the prosecution to prove soundness of mind. For a defence of insanity to be sustained in a criminal case it must be proved, first, that at the time of the act the accused person was labouring under a certain defect of reason; secondly, that that defect of reason was due to a disease of mind; and then a third thing must be proved—namely, that because of that disease of mind, manifesting itself in a defect of reason, the person did not know the nature and quality of his act, or (not "and") did not know that what he was doing was wrong. Lord Hewart appeared to think that the word "irresponsibility" begged the question, and to dissent strongly from the doctrine of "uncontrollable impulse," pointing out that, after all, one of the most important functions of the law is to make people control their impulses. He deprecated any relaxation of the stringency of the law which would make insanity an easier defence, though he paid a high tribute to the "delicate and exquisite inquiries" of the mental specialists. Dr. Hyslop took rather a different line. He wanted to know how the M'Naghten rules applied, for instance, to dream states in which crimes were committed. He had known a person commit a crime evidently in a state of post-epileptic automatism, and suffer the extreme penalty; which might be good law, said Dr. Hyslop, but was bad medicine. It must be recognized that there were conditions of irresponsibility not due to certifiable disease. Insanity and irresponsibility were totally different things. Very often in the courts evidence was heard on the question of insanity—evidence which might be relevant to the point at issue or not; but when the jury were charged a totally different problem, that of responsibility, was presented to them, and so judgement was given on a point never tried. Dr. Hyslop's view, that there was any permanent dissonance between medicine and law, was not accepted by the Lord Chief Justice, who said that he hoped to discuss this matter with Dr. Hyslop in the Elysian fields; but he felt bound to point out that truth, which comprehended both legal truth and medical truth, was one and entire. He added that in all his experience he had never known one case of a man who in the largest acceptance of the word was insane being punished as a criminal. That is certainly comforting, even though it must be ascribed to Providence rather than to the law.

COMPLIMENTARY DINNER TO SIR ROBERT BOLAM.

MEMBERS past and present of the Council of the British Medical Association gave a complimentary dinner at the Hotel Victoria, London, on April 7th to their Chairman, Sir Robert Bolam, in order to offer him their congratulations on the honour recently conferred upon him by the King. The PRESIDENT OF THE ASSOCIATION (Dr. F. G. Thomson) was in the chair, and was supported by Dr. Brackenbury, Mr. Bishop Harman, Dr. J. A. Macdonald, Sir Jenner Verrall, and Sir Dawson Williams. Besides those attending the Council meeting, numbering between fifty and sixty, five former members of the Council were present—namely, Sir James Barr, Dr. E. R. Fothergill, Dr. John Goff, Dr. C. Sanders, and Dr. Johnson Smyth. The officials of the Association also joined in the occasion.

The PRESIDENT, in proposing Sir Robert Bolam's health, said that it was always a source of wonder and admiration to him that any man should be able to carry on the active work of his profession at home and at the same time preside over the affairs of the Association in London. This dual existence entailed innumerable nights on the London and North-Eastern Railway, and could only be sustained, whatever the capacity for physical endurance, by a high sense of public duty. Not only had Sir Robert presided over the Council for nearly six years—and they all hoped he would continue to hold the office—(applause)—but he had in some subtle way gained the affection of all the members and was looked upon as their wise and considerate friend.

Dr. BRACKENBURY testified to Sir Robert Bolam's personal kindness to himself on many occasions, both in connexion with the Association's work and with other matters. Of Sir Robert's services and sacrifices for the Association and the profession it was scarcely necessary to say anything in such a company. He would be inclined to describe them as unparalleled were it not that he recalled corresponding services given in years past by Dr. Macdonald and others, who also carried on their practices in some distant town and yet devoted many days in the course of many years to the Association. The Chairman of Council had great gifts of management and persuasiveness. He remembered occasions when Sir Robert and he had tried their persuasiveness upon one another; the process was interesting, and the result, no doubt, was to keep them both on the straight and narrow path. The Chairman was an extremely wise man, in the best sense, that he could be trusted to do the wise and the right thing. Not only had he wound himself into their intellectual concerns, but he had endeared himself to their hearts. The honour bestowed upon him had gladdened them all, and they hoped he would be spared many years to wear it. (Applause.)

Dr. J. A. MACDONALD asked what there was in the British Medical Association to induce men to sacrifice themselves on its behalf—men like the late Sir Victor Horsley, the late Sir Clifford Allbutt, Sir James Barr, Sir Jenner Verrall, Sir Dawson Williams. Whatever might be the make-up, the complex, the divine afflatus which caused such men to spend themselves for the Association, it was certainly most pronounced in the guest of the evening, *primus inter pares* of this very distinguished society. His expenditure of time and energy, his acute business ability, the distinguished success which had attended all that he had attempted to do, made his colleagues grateful. His Majesty had been wisely advised to confer the dignity of knighthood on Robert Bolam, and in so doing had honoured the Association and every member of it. (Applause.)

Sir JENNER VERRALL, the senior member of the Council in respect to length of service, said that when he thought of Sir Robert Bolam he recalled a phrase familiar in his youth, *Totus teres atque rotundus*. Could any epithets be more appropriate, especially *teres*? When they studied anatomy they were introduced to *teres major*, not knowing that they were ever to meet the superlative, but after all these years here it was in the person of their guest—*teres maximus*. Sir Robert Bolam's method of argument

was sound, suave, moderate, and convincing. Many kind thoughts and wise schemes were born in that busy brain, some had been realized, but some must have been put aside for future use. If the Association owed a debt to Sir Robert, he also owed a debt to the Association in that it had given him the chance of doing a labour of love.

Sir DAWSON WILLIAMS, who spoke as representing the staff of the Association, said that when Dr. Bolam (as he then was) took the chair of the Council in the year of the Cambridge meeting everybody anticipated that, coming as he did from sunny Newcastle, he would prove a shrewd judge of men and policies. But they did not wholly anticipate—and they were not always quite pleased to discover (laughter)—how shrewd he was. It was a serious matter to the permanent staff when a new Chairman of Council took office—the more serious in this case because the staff had grown to know and love and rely upon his predecessor. But it was not long before they found that Dr. Bolam was determined, even though he lived at the other end of the country, to enter into all their troubles and difficulties, that he would always take care to understand a particular difficulty, and they came rather to think—at least the speaker did—that if the Chairman, after he had understood it, made little of it, he, the official, and perhaps some of his colleagues, had been making too much of it. They had all been astonished at the way in which he had given time to the Association's affairs. He had frequently attended committee and other meetings in London which lasted a few hours but had cost him two nights in the train. He wished, on behalf of his colleagues on the staff, to thank Sir Robert Bolam for the way in which he had treated the officials. They were sincerely glad when he was honoured by the Crown; they felt that no honour was ever better bestowed, and they were glad also to think that he had received from the Association, in addition to the responsibilities it had cast upon him, the honours which were within its power to confer. But he had something more—the sincere affection and esteem of all the members. (Applause.)

Dr. J. GIBSON, on behalf of the Irish members of Council, and Dr. HUGH MILLER, on behalf of the Scottish, associated themselves very heartily with the congratulations.

Sir ROBERT BOLAM, who was enthusiastically received, said that during the five and a half years of his chairmanship he had had the highest satisfaction that a man could have who set out to do a little work for the good of the profession and for the community generally—namely, the approbation of those best qualified to judge of that work. He was glad to see the President with them that evening; it was only now, after Dr. Thomson's long illness which had debarred him from active participation in the Association's affairs during his year of office, that they had the opportunity of appraising his powers and gifts. Dr. Brackenbury had said some things in the way in which only he could say them, and which he would always treasure. From Dr. Macdonald he had received most generous support; his own work on the Council was only possible in the earlier years of his office by the advice and help of his predecessor. Sir Jenner Verrall, if the oldest in years of service on the Council, was the youngest in spirit, and had been a tower of strength to him. He was grateful also for the kind words that Sir Dawson Williams had spoken. It was the happiest thing in the life of an honorary officer to feel that those who were part of the permanent machine could regard him as a fellow in the work which they really had the heavy burden of carrying through. Like others in medicine, he had gone to the Editor for advice on many subjects and had always received it ungrudgingly. It was a great regret that Alfred Cox was not present. It was from Cox—an old college mate and a dear friend—that he learned some of the things which had made his friends speak of him with such kindness that evening. One of those things was that there was something fine in the ideal of an Association like this; he had been led to understand that, as Kipling said about something very different, "the game is more than the player of the game, and the ship is more than the crew." He had striven after an ideal beyond his accomplishment, but of which he hoped to grasp the skirts, and to understand what measures were best conducive to the greatest

happiness of the greatest number, being careful to act in all things with a large toleration. He had doubtless many times troubled his fellow members of Council, and he knew that many times they had troubled him! But he had been sustained by a rhyme from the same author:

And when they bore me overmuch, I will not shake mine ears,
Recalling many thousand such whom I have bored to tears.
And when they labour to impress, I will not frown nor scoff;
Since I myself have done no less, and—sometimes pulled it off.

With regard to his recent honour, the greatest satisfaction had been the pleasure which it had given to others than himself. He had had to answer between seven and eight hundred letters from members of the Association far and wide, and in all of them the note of affection had touched him most deeply. He thanked them again for their kind expressions. The knowledge of their approval would help him during the rest of his work, and in the time of his retirement, which must fast approach, the kindly affection which had radiated through the speeches that evening, as well as through all the intercourse of these five and a half years, would be cherished very highly. (Loud applause.)

The proceedings closed with the toast of "The President," proposed by Sir RICHARD LUCE, and Dr. THOMSEN, in reply, spoke of the disappointment he had felt in not being able to take part in the work of the Association during his official year.

THE INTERNATIONAL CONGRESS OF SURGERY.

THE seventh International Congress of Surgery was held at Rome from April 7th to 10th, under the patronage of the King of Italy and the presidency of Professor Giordano of Venice. It was attended by no fewer than 355 surgeons from every part of the world, and the total attendance reached 600, thus exceeding that of any previous meeting of the Congress. A meeting held in Rome must in any case be memorable, but certain circumstances have made this meeting unique, and have left upon those who attended it an impression not readily effaced.

We met in the Hall of the Conservators, a magnificent room in one of the great buildings standing on the site of the Capitol. The room itself spoke of the glories of the Renaissance, but its foundations were the cradle of ancient Rome and the very birthplace of our civilization. The room was packed to overflowing with surgeons from every quarter of the globe when the head of the Italian Government, the Governor of Rome, and the officers of the Congress took their seats. The setting was magnificent, the company was not unworthy of its meeting place, but it is no exaggeration to say that both were swept from our minds by the personality of one man—Mussolini. I have never before been conscious of so instant and general an impression. We felt that we were in the presence of one of the great forces which move the world. Quiet confidence, perfect self-control, unlimited power—these were written in every feature of the man before us. We waited for him to speak.

He spoke in Italian with all the easy fluency of a master. He spoke with pride of Italy as the first home of our art, dwelling particularly on Vesalius. He passed on to make a graceful reference to Ambroise Paré, and his work for soldiers in the mediaeval wars, and of all that surgery had done for wounded soldiers, himself included, in the great war. He welcomed us as the guests of the Italian people; and as we listened we began to understand a little, perhaps even to feel in some small degree, the affection of Italy for Il Duce.

The business was largely formal and the meeting short, and we crowded to the windows to see the high officials drive away. Mussolini had just appeared, when suddenly we heard the sharp crack of a revolver, and a moment later we saw his face covered with blood. A crazy woman with a revolver concealed beneath her scarf had fired point-blank from within three feet of his face. The scene that followed was indescribable. Mussolini disappeared into the entrance. None of us knew whether he had been killed, and no one knew what might follow. Happily he appeared a few minutes later, his face bandaged up, but apparently none

the worse, and Rome gave itself up to a day of demonstrations and thanksgiving. Everywhere his escape was the one topic of conversation, and we learnt many things. Perhaps Southern blood is emotional, but that will scarcely explain all that we saw and heard. Mussolini has gained a power over the hearts of his countrymen that can be for nothing for good. Such utter confidence, such implicit devotion, such deep and enduring affection, would be dangerous if they were offered to most men. It is well that we in England should realize that to Mussolini they are offered without measure. In his hands they are safe, and they are the sure foundations of the future of Italy. Without any doubt at all he is at this moment the strongest man in Europe.

The professional meetings of the Congress opened with a discussion on the treatment of cancer of the uterus by radium and x rays. Professor Regaud of Paris, opening the discussion, made a strong plea for the introduction of radium into the uterine canal, as opposed to the use of needles. External radiation may be used separately or as an adjunct, but the best results are obtained by the use of powerful tubes, well filtered, placed at such a distance that the rays pass through a large area of the skin. He stressed the importance of the removal, so far as possible, of microbic infection before the commencement of treatment. Beutner of Geneva was so impressed by the value of radium and x-ray treatment that he advised it even in operable cases. Forsdike of London held a more conservative view, but the immense value of these methods of treatment was universally maintained.

An interesting discussion on the treatment of cerebral tumours was opened by Brun of Lucerne. Basing his remarks on a personal experience of 458 craniotomies, he described his own technique in detail. He laid great stress on haemostasis, considering that collapse in the later stages of an operation was often due to carelessness in stopping bleeding in the very first incision. This he makes an inch at a time, picking up every bleeding point as he advances. He always operates under local anaesthesia, the patient sitting comfortably with his head resting on his folded arms. The bone he divides with Krause's forceps, plugging the slit in the bone with gelatin gauze to stop haemorrhage from this source.

In the discussion which followed the chief points brought out were the importance of early diagnosis, the superior value and the greater safety of a one-stage operation whenever it could be performed, and the great value to the surgeon of a personal training in neurology and of a knowledge which would enable him to diagnose for himself the finer points in the pathology of each case.

Several new instruments of interest were demonstrated, including a most ingenious trephine by Jentzen of Lausanne and a new type of craniotome by Souttar.

Discussions on the surgery of the spleen and of Jacksonian epilepsy, and a valuable paper by Adson of the Mayo Clinic on the treatment of trigeminal neuralgia, were included in a very busy meeting of the Congress. It will be memorable for one other circumstance—that at the general meeting it was decided by an overwhelming majority to admit Germany once more to the meetings of the Congress so soon as she shall have become a member of the League of Nations. The next meeting of the Congress will be in Warsaw in 1929. H. S. SOUTTAR.

THE UNITED STATES ARMY MEDICAL REPORT.

THE annual reports on the health of the United States Army are considerably more voluminous than the reports on the health of the British Army, and are prepared more expeditiously. Thus the annual report for 1925, containing some five hundred pages, has already been published; but it should be noted that for statistical purposes it only relates to the year ending December 31st, 1924, and for administrative purposes to the fiscal year ending June 30th, 1925.

The Surgeon-General, Major-General Ireland, summarizes the report in an interesting letter of transmission, covering the first sixteen pages. This is followed by a detailed

¹ Annual Report of the Surgeon-General U.S. Army, 1925. Washington: Government Printing Office, 1925. (8vo, pp. xvi + 483; 185 tables in text, 9 appendix tables, and 50 figures.)

account of the health of the army, with the usual vital statistics and an account of the incidence of individual diseases, groups of diseases, and injuries. Half of the report is taken up with these details; the remainder contains an account of the administrative work of the medical services and of the dental, nursing, and veterinary corps, all of which come under the Surgeon-General's administration, the various schools of instruction, the work of the medical services in the different commands of the United States and oversea garrisons, and details of the medical services in the eight general hospitals of the United States Army. All these sections of the report are amplified by 185 tables, 50 charts, and, as an appendix, 9 elaborate tables of statistics.

The mean annual strength of the army for the calendar year 1924 was 135,640, exclusive of the Army Nurse Corps, which had a strength of 845. The number of officers was 11,219. The number of the enlisted men was 110,862 white Americans, 4,186 coloured, 7,056 Filipinos, and 2,317 Porto Ricans. They were distributed to garrisons in the Philippine Islands (11,821), Hawaii (12,493), Panama (8,561), China (919), and Porto Rico (1,308), in addition to the garrisons in the United States.

In estimating the ratio of admissions to hospital, the report distinguishes between the admissions for disease and admissions for injuries, and emphasizes the fact that the former, 535.45 per 1,000 of strength, shows a slight decrease over the previous year, whereas the latter shows a very considerable increase—from 107.75 per 1,000 to 120.75. The death rate from disease was the lowest recorded, 1.94 per 1,000, as was also the death rate from diseases and injuries combined, notwithstanding an increase in the actual number of fatal accidents. A remarkable fact, however, is brought out in the report—namely, that the leading cause of death was not infectious diseases, but suicide; as was also the case in the year 1923. Tuberculosis came next as a cause of death, followed by automobile accidents, which advanced from seventh place in the statistics of mortality in 1923 to the third place in 1924. Balloon and aeroplane accidents came next. The increase in deaths from injuries or external causes has resulted during the last three statistical years in a ratio exceeding or equal to the deaths from disease amongst the white enlisted men in the United States. The statistics of suicide and homicide are recorded for the past ten years, and of automobile and aeroplane accidents for the past eight years. During these periods there were 1,015 suicides, the highest rate being amongst officers; 254 homicides, chiefly amongst the coloured troops; 463 deaths from automobile accidents, causing a death rate in 1924 much above the average for the eight-year period and higher than in any previous year; and 874 deaths from aeroplane accidents, excluding battle casualties during the war.

There is little else of special interest in the report regarding the causes of admission and deaths from disease. Amongst the white troops bronchitis heads the list as the chief cause of admission, followed by tonsillitis and gonorrhoea. Amongst the coloured troops in the United States syphilis comes first, gonorrhoea next, and then bronchitis. Malaria and undetermined fevers were the chief cause of admission among the Filipino troops; and bronchitis, tonsillitis, and rhinitis amongst officers in all countries. Only four cases of typhoid fever were recorded, one fatal case having acquired the disease previous to prophylactic inoculation. Alcoholism and drug addiction continue to account for a considerable number of admissions, as many as 23.35 per 1,000 of the white troops in the Philippines being admitted for the former and 2.43 per 1,000 for the latter.

With regard to invaliding, the most frequent cause of discharge was nervous diseases, such as dementia praecox, psychopathic state, mental deficiency, and epilepsy, accounting for 41.3 per cent. of the total discharges.

There is much that is of interest and instruction in connexion with the administrative records of the medical services. There is the same difficulty as here in obtaining medical men for army service, owing, as Major-General Ireland states, to the great demand for young medical men in civil life. The number of medical officers on June 30th, 1925, was 924, or 59 below the authorized strength. The authorized strength of other ranks of the medical department was 6,850 Americans, including 640 for veterinary

service, and 385 Philippine scouts. The actual number on June 30th, 1925, was 6,465. But, in addition to these, 1,307 civilians were employed in hospital service, and 299 in depots and administrative service. Amongst preventive measures that appear to be new are annual physical examinations of commissioned personnel for the early detection of physical defects and the correction of such as are remediable by personal hygiene and medical or surgical treatment; 11,789 officers were so examined during the year and 3,812 found in need of some form of treatment or professional advice.

In the review of the report for the year 1924, which appeared in the *BRITISH MEDICAL JOURNAL* of May 16th last, reference was made to the new "Army Medical Center" near Washington, and to the various courses of instruction for the medical personnel of the United States Army. In the report for 1925 these are again described in detail, and offer much instructive reading to all interested in the training of medical and nursing services and their reserves for military medical duties. It would appear from the report that the whole of the civil medical resources and medical supplies in the United States are being systematically organized for mobilization purposes in the event of war—a somewhat curious comment on the loud-spoken demand for disarmament.

THE HOSPITALS OF NEW ZEALAND.

The report of the Director-General of Health of the Dominion of New Zealand for 1925 contains a section dealing with hospitals. It is of much interest. The Director-General would appear to correspond with the combined offices known in our English Ministry of Health as that of chief medical officer and that of chief secretary. The report is a complex document and corresponds to nothing with which we are familiar in this country, for it covers all the hospitals in the Dominion, and includes the work that is done there in voluntary hospitals; Poor Law institutions; the hospitals of sanitary authorities; central Government institutions, including prison hospitals; homes for aged persons; and "charitable aid, indoor and outdoor," which seems to be much what we know as Poor Law relief; district nurses; and subsidies to doctors in outlying districts. It is therefore difficult to make any just comparison between the hospital system of the Dominion and our own, yet there are some points of contact.

Though in New Zealand the returns of the local hospital boards are prepared on a uniform system, it is pointed out that this gives no basis of comparison between the hospitals. The costs of hospitals for acute surgical or medical cases, for chronic cases, consumptives, homes for old people, maternity and fever wards, cannot be compared. Further, some hospitals are almost self-contained, employing their own staffs for repairs, baking, laundry, and the like; others put these out to contract. The proper basis for comparison would be through a businesslike system of departmental costing. "There is nothing to distinguish the financial administration of a hospital from any other business concern. From the standpoint of financial administration a hospital is an hotel for the sick, and should be subject to the same or even greater business management as would an hotel catering for the same number of guests." The knowledge of this method of costing is stated to be highly beneficial to the staffs of hospitals. "There is, moreover, nothing more stimulating to the staff of an institution than to be furnished with a clear return of the cost of its particular departments, and this especially applies in the case of quantity consumption of certain articles or services in individual wards. Part of every probationer's training should be the encouragement of an intelligent interest in the cost of hospital treatment for which she, together with others of the staff, is responsible." Reference is made in the report to the work of Mr. Stone, the accountant of St. Thomas's Hospital, London, where a complete costing system has been worked out with much success. The revenue of the hospital system is derived from several sources. The rates are drawn upon to the extent of 34 per cent. of the total costs; voluntary contributions furnish 2.9; patients' payments 14.7; charitable

The report for the year 1925 showed that the number of cases treated in the hospital had been 1,854, the highest yet reached in the history of the institution. The total number of cases treated, both as in-patients and out-patients, was 2,934. In addition to this, there had been 5,418 attendances at the ante-natal clinics, of which 1,237 were new cases. An urgent appeal is made that the subscription income should be augmented, because the accounts show a debit balance of £1,161 on the year's working, as compared with a debit of £1,094 in the previous year.

The annual meeting of subscribers to the Glasgow Royal Cancer Hospital was held on March 26th. Sir John M. MacLeod, Bt., LL.D., who presided, moved the adoption of the report, which showed that 300 cases had been treated in hospital during the year 1925, and 26 had attended the out-door department, while the district nurse had made 936 visits. On the ordinary account there had been a deficit of £1,294, but deducting sums expended on the new x-ray department there had been a surplus of £567. Professor Muir, in seconding the adoption of the report, expressed the opinion that a much wider view ought to be taken of cancer research. If regard was had merely to the enormous amount of work which had been done during the last twenty-five years, and the number of men in various countries who were devoting themselves to this work, the apparently small results of a practical nature were apt to be discouraging. Research, however, was directed towards two ends—one to find the cause of the disease and the other to find the cure. In some diseases the cure had been found before the real nature and cause of the disease was known. On the other hand, there were many diseases in which the exact cause was known, but for which no direct cure was yet available. Still, looking at infective diseases, he thought it might be said that in practically every case the discovery of the cause of the disease had brought with it the means, to a certain extent, of controlling the disease and diminishing its ravages. Much had been done in recent years to bring medicine nearer to an understanding of the nature and therefore of the cause of cancer. Sir George Beatson, in acknowledging the vote of thanks to the medical staff, said that the directors were taking steps to obtain a larger supply of radium. The cost of a gram of radium, which was the amount they desired, would be over £11,000, and towards that figure a legacy of £2,000 and some other contributions had already been received.

PRINCESS LOUISE HOSPITAL FOR LIMBLESS MEN.
The ninth annual meeting of the Princess Louise Scottish Association for Limbless Sailors and Soldiers at Erskine, near Glasgow, was held on March 29th in the City Chambers. Lord Provost Sir Matthew W. Montgomery presided. The report stated that the committee was at present considering steps to place the hospital on a permanent footing among the philanthropic institutions dedicated to those who had suffered during the great war. It was hoped in the course of the coming year to formulate a permanent scheme which would attract a sufficient number of deserving cases. The report indicated that at the end of the preceding year 121 men had been working, comprising thirty-eight persons in training under the industrial training scheme and fifty-two men working under the new scheme for the employment of severely disabled men, together with thirty-one journeymen. Fourteen men who had completed training and remained in the boot-making department produced during the year 1,250 pairs of orthopaedic boots and fifty pairs of private orders, together with 5,278 repairs. The hospital was in a satisfactory financial position, as legacies and subscriptions amounting to £5,935 had been received during the year, and the income had exceeded the expenditure by £299.

Dr. A. Logan Turner, President of the Royal College of Surgeons of Edinburgh, referred to the research work done in the hospital and mentioned the question of a site for the proposed new Maternity Hospital. Two requirements were necessary in the selection of a site. The first was the proximity of the hospital to parts of the town from which the patients were drawn. There must, at the same time, be close contact between the hospital and the scientific department of the medical school. One of the attractions of the Edinburgh medical school had been the centralization within a limited area of the various units which went to make up the school. If it were possible to obtain a site for this hospital on the ground obtained by the managers of the Royal Infirmary from George Watson's College, that site would be ideal. Councillor Dr. Nasmyth, chairman of directors of the Maternity Hospital, said that

INFLUENZA AND ENCEPHALITIS LETHARGICA IN GLASGOW.

In the report for March the public health department for Glasgow states that the average death rate for the month was 16.9, as compared with 15.2 in the corresponding month of last year. The increase was due to deaths from respiratory diseases, the result of the widespread prevalence of acute influenza and pneumonia. In one week 116 persons had died from pneumonia, 87 in the preceding week, and 39 in the week before that. A rather disquieting feature was that in a number of cases attacks of influenza had been followed by encephalitis lethargica. The Scottish Board of Health had requested the Glasgow Parish Council to consider the question of providing accommodation for the treatment of forty or fifty patients in the later stages of encephalitis lethargica, and the hospital committee had agreed to give effect to this suggestion.

ANNUAL CONFERENCE OF THE NATIONAL ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS.

The twelfth annual conference of the National Association for the Prevention of Tuberculosis will be held in Glasgow from July 1st to 3rd. The subjects to be considered include provision for the care of non-pulmonary forms of tuberculosis; this discussion will be opened by Dr. A. S. M. Macgregor, medical officer of health for Glasgow, and Mr. James Taylor, consulting surgeon to the Glasgow Corporation hospitals and sanatoriums. Sir Robert Philip and Dr. Lissart Cox (central tuberculosis officer of the Lancashire County Council) will open a discussion on the actual place and function of the tuberculosis dispensary in the tuberculosis scheme. Communications dealing with the recent advances in tuberculosis will be made, and visits have been arranged to representative housing schemes, hospitals, sanatoriums, and to the new laboratories of the Glasgow Corporation. The conference is open to all persons interested in tuberculosis on payment of the fee of one guinea, either as delegates or as private members. It is stated that the Ministry of Health will be prepared to sanction the payment of the reasonable expenses of attendance at the conference of not more than three delegates from a local authority, among whom should be included the medical officer of health, or the chief clinical tuberculosis officer, or both. Further information may be obtained from the Secretary, National Association for the Prevention of Tuberculosis, 20, Hanover Square, W.1.

Ireland.

MEDICAL ORGANIZATION IN NORTHERN IRELAND.

In our issue of April 3rd (p. 632) a paragraph was published in the course of which it was stated that at a meeting of medical men in co. Tyrone a resolution had been passed to the effect that the Belfast Medico-Political Committee did not represent the medical profession throughout the Six Counties. The reply of the Medical Committee of Northern Ireland was published also. Since then Dr. W. Lyle has written a letter on behalf of the co. Tyrone doctors, in the course of which he states that on the Medical Committee of Northern Ireland there were four delegates from co. Tyrone, and this committee was, he understood, formed for the sole purpose of preparing evidence to place before the Poor Law Commission, and, having done so, he, in common with the other members of the Tyrone Local Medical Committee, presumed that it ceased to function. There was, however, previous to its formation in October, 1924, some sort of committee, which was formed in Belfast, which purported to represent the profession throughout Northern Ireland, and which made representations to the Government in the name of the profession; this is the committee to which the resolution of the Tyrone Local Medical Committee referred under the title of the "Belfast Medico-Political Committee." As a matter of fact, at one of the meetings of the Medical Committee of Northern Ireland held either late in 1914, or early in 1915, very great dissatisfaction was expressed by many of the delegates with the inadequate representation of the pro-

fession, outside Belfast, with the result that a list of provincial doctors was chosen, and the secretary to that meeting promised to have these names added to its membership; down to the present time, however, no intimation had been received that this had been done. Further, whilst the president and secretaries of the Medical Committee of Northern Ireland stated in their first letter that the membership of their committee included two representatives from each of the Six Counties, there were four representatives from co. Tyrone duly appointed according to instructions from headquarters and actually present at meetings of the committee held subsequent to October 31st, 1924, and in their letter they gave the names of three representatives of this county, so that the Tyrone doctors might be excused for feeling uncertain as to how, if at all, they were represented on the committee, by whatever name it was called, which spoke to the Government and to the public in the name of the entire medical profession of Northern Ireland. If, however, the president and secretaries of the Medical Committee of Northern Ireland, on which co. Tyrone had three representatives, could assure them that this was the only committee now representing the medical profession in Northern Ireland, he (Dr. Lyle) believed the co. Tyrone doctors would be satisfied.

WOMEN'S NATIONAL HEALTH ASSOCIATION.

At the annual general meeting of the Women's National Health Association, Dr. Barry, in her report on the work of the babies' clubs, said that their aim was to get into touch with the very poor and miserable people. The membership of the clubs was now 3,451, and the attendances at the clubs for the year 27,166 mothers, 17,998 infants, and 20,082 children. There had been 10,946 consultations with doctors, 447 had received medical treatment, and 237 had been sent to fresh-air convalescent homes. Cash for drugs and food distributed at reduced rates by the clubs amounted to £1,818 6s. 0½d., and £348 15s. 7½d. worth of drugs and foods had been issued free. An ultra-violet light lamp for the treatment of children suffering from rickets and malnutrition had been set up during the year, and was working very successfully. The women were taking a great interest in the health lectures. Professor Bigger spoke of the need of a pure milk supply in Ireland. It could not be said that the milk supply of Dublin was very satisfactory, but the demand for bottled milk showed that the people wanted better milk; yet it frequently happened that milk out of a bottle was no cleaner than that out of a can. No producer in Ireland, so far as he knew, could supply milk which would satisfy the grade demanded in England. The public should pay no attention to the claims made by any trader in Ireland who stated that his milk was grade A. The methods used for dealing with food, fruit, and milk all required attention. This was particularly true of bread. Milk was only one of the foods that had to be protected. The following resolution was adopted:

That we strongly urge the public health authorities to make provision for the protection of milk, and to ensure a free supply for children from 1 to 5 years; and also to educate the public as to the value of milk as a food, and the importance of having it hygienically handled.

England and Wales.

PRESENTATION TO DR. JOHN RUSSELL.

DR. JOHN RUSSELL, after forty years' medical practice in North Staffordshire, is about to return to his original home in Scotland, and has recently received various tributes of esteem. On March 31st, at a meeting of officers and members of the Voluntary Aid Detachments, under the presidency of Dr. Charles Reid, county controller for Staffordshire, an inscribed gold cigarette case was presented to Dr. Russell. The chairman described the valuable services rendered by Dr. Russell to the British Red Cross Society, of which he was the vice-president of the Stafford division. During the war Dr. Russell served as assistant county controller of Voluntary Aid Detachments, and was one of the most active and reliable members of the executive committee. His calm judgement and untiring

energy had been associated with a valuable capacity for raising large sums of money for charitable purposes. On April 8th a complimentary dinner was given by the members of the Stoke-on-Trent Insurance Committee to Dr. Russell, its vice-chairman, and Alderman Brookhouse, its chairman, both of whom had been members of the committee since its inception in 1912.

CENTRAL MIDWIVES BOARD.

The Central Midwives Board for England and Wales met on March 31st for a penal session and on April 1st for the ordinary meeting; Sir Francis Champneys, Bt., M.D., presided at both meetings. At the ordinary meeting Sir Francis Champneys was re-elected chairman, and the following re-elections were announced: Dr. Marguerite Douglas-Drummond, Miss Edith Greaves, Miss Olivo Haydon, Dr. F. N. Kay Menzies, by the Ministry of Health; Dr. W. S. A. Griffith by the Royal College of Surgeons; and Dr. C. Sangster by the Society of Apothecaries of London. The Board approved the suggestion of the Minister of Health that since the revised regulations for the notification of ophthalmia neonatorum would not come into force before July 1st, the alterations in the rules which had been submitted should be also deferred till that date. The Board approved for the year ending March 31st, 1927, the revised lists submitted by the secretary of examiners, lecturers, and institutions where lectures are delivered, and the institutions, homes, and midwives at which and under whom midwives may be trained.

Correspondence.

HERBERT JONES TESTIMONIAL.

SIR,—In your issue of March 20th (p. 540) you commended the proposal to present a testimonial to Dr. Herbert Jones. All members of the profession should subscribe to this acknowledgement of the good work of Dr. Jones in raising the status of the profession in the public estimation. Those who belong to the public health services should welcome the opportunity, especially the younger members who now enjoy good salaries owing to the efforts of Dr. Jones and others who in but few instances reaped any benefit for themselves. Subscriptions may be sent to Dr. John Steed, Staunton-on-Wye, Hereford.—I am, etc.,

Chesterfield, April 3rd.

HERBERT PECK.

* * A few days after the receipt of Dr. Peck's letter the preliminary list of subscribers to the testimonial was forwarded by Dr. Steed, who expresses the hope that it may serve as a reminder to others desirous of supporting the testimonial. The names of subscribers and amounts promised are as follows:

43 3s.—The Editor of The Medical Officer.
42 2s.—Messrs. Ainslie and Hepper (Hereford), Drs. L. J. Blandford (Ruddington), John C. McVail, J. E. O'Connor (Leicester), J. J. Paterson (Maidenhead), Herbert Peck (Chesterfield).
11 1s.—Dr. E. H. Baldock, Dr. A. Middleton Brown, Mr. W. B. Butler, Professor J. T. Cash, Mr. E. W. Du Buisson, Drs. S. L. Corry, Hugh Penton, Cyril Francis, J. Oswald Lane, J. H. Lilley, and Peter Lowe (M.D.H.), Mr. F. S. Machin, Mr. E. Wood Power, Mr. J. A. Pritchard, Dr. B. W. Stallard, Dr. F. H. Thompson, Lieut.-Colonel Wanhall (the foregoing are all of Hereford). Drs. Basil Adams (Nieuport Sanatorium), J. Ridley Bailey (Bilston), G. F. Buchan (President, Society of Medical Officers of Health), W. H. Cam (Ross), H. C. Clark (Wellington), W. Allen Daley (Hull), Q. R. Darling (intardine), W. S. Davies (Bristol), G. W. urds (Kington), H. R. R. Fowler (Ledbury), J. H. (Dilwyn), Richard Harding (Kington), Wells), Drs. F. C. H. Home (Tarrington), T. A. Jones (Ledbury), H. V. Lamb (Ledbury), A. W. McMichael (Vowchurch), A. Milner (Kington), W. H. Morgan (Ewyas Harold), Sir Arthur Newsholme, K.C.B., Drs. Norman H. Pike (Cheltenham), E. G. Salmon (Finsbury Park), J. Grimmond Smith (Burgill), E. H. Snell (Coventry), John Steed (Staunton-on-Wye), Gerard Steel (Leominster), A. S. Underhill (Barnes), E. Walford (Walmers), James Wheatley (Shrewsbury), E. G. H. Williams (Colwall), Mary Williams (Colwall).
11.—Professor A. E. Boycott, F.R.S. (London).
10s. 6d.—Dr. A. M. Humphry (Pontillas), Dr. W. Lucas Johnstone.

MURDER AND THE DEFENCE OF INSANITY.

SIR,—In the course of the last few months there have been appearing in the BRITISH MEDICAL JOURNAL certain very interesting contributions on the question of murder and the defence of insanity, and it so happens that in the

course of my service I have had from time to time the duty of performing the work of superintendent of sundry jails. In this way the following cases came to my notice, and I submit them to you as it seems to me not unlikely that they have some bearing on the point at issue.

1. In the year 1919 a man was convicted of the murder of a woman who was six months pregnant, and was sentenced to death. In this case it came to light that this man had been for many years suspected, with good reason, of having been the cause of more than one case of criminal assault on young women of his village tract; it also came out in evidence that he had killed the woman and had thereafter "outraged" her. On the prisoner being committed to jail for execution, and on reading over the judgement of the court and the evidence in the case, I referred it to the chief of the executive, and the prisoner was reprieved.

No sexually sane Burman will rape a pregnant woman, still less will he kill her and then outrage her. The executive had obviously failed for many a year to have sent this man to a lunatic asylum.

2. In the year 1920 B. S. was convicted of the offence of the murder of his superior officer and was sentenced to death. In this case the following facts came to light. (i) A man (B. S.) had served in Mesopotamia and there he had been rather tyrannized over by a certain non-commissioned officer. (ii) There was a good deal of ill feeling between this man and the non-commissioned officer. (iii) On one occasion B. S. went to answer a call of nature while in the line at Sanna-iyat, and on coming back had a drink out of his water-bottle; the water seemed to taste a little worse than usual and B. S. remarked on this, whereupon he was informed amid the jeers of his comrades that the non-commissioned officer in question had urinated into his water-bottle. (Those medical men who served in Mesopotamia will realize that the actuality of this occurrence may be open to question when they remember the chlorinated filth we had to drink there.) B. S. admits frankly that from this time he did try many times to shoot this non-commissioned officer. (iv) He returned from service without being able to carry out his intention, and went to an up-country battalion of the military police. There he found this non-commissioned officer promoted to commissioned rank, and there the tyranny became worse; in the end he shot this commissioned officer stone dead. (v) On the prisoner being committed to jail for execution and on reading over the judgement of the court I referred the case to the chief of the executive and the prisoner was reprieved.

This B. S. was a fairly high caste Hindu; whether the defilement of his water-bottle had or had not actually taken place, there is no shadow of doubt but that this man knew himself to have been defiled for all eternity by the fact of his having drunk this pollution. I have not the slightest doubt in my own mind but that B. S. knew that he was doing a thing which was illegal, but I am equally certain that it was impossible for B. S. to refrain from carrying out the suggestion that he should kill the man who had done him this irreparable injury.

3. In 1920 M. T. N. was convicted of the offence of the murder of his sister-in-law and of her aunt, and of the attempted murder of his aunt. This happened on a boiling hot August afternoon, and I reached the hospital practically synchronously with M. T. N., followed by the dead body of his sister-in-law, by her aunt, and by his aunt. The second died at the entrance to the hospital. The third received immediate attention and lived in the face of all probability. M. T. N. himself was in a condition such as I have never seen before. The man appeared to be shivering with cold; but on noticing him carefully I found that it was not the case—that he was showing rapid contractions of whole muscles but fibrillary contraction of individual groups of fibres in many different muscles in a very irregular manner. He had made a futile kind of attempt to kill himself, apparently by cutting across the back of his neck with the "dah" (something like a meat chopper) which he had used to kill the two women. Otherwise he was quiet—much too quiet.

The simplest way that I can put it is that the man was a rational automaton. He did what he was told to do; he answered questions rationally; he sat down to have his wounds dressed; he helped to hold a dressing tray; but it seemed to me that he did not realize what he was doing. On reading over the judgement of the court when M. T. N. was committed to jail for execution I referred the case to the chief of the executive and the prisoner was reprieved.

The facts in this case were as follows: (i) M. T. N. used to make a thatch material for roofing indigenous people's houses. His wife used to sell odds and ends in the bazaar. His sister-in-law used to do the cooking for the household and used to help in the thatch work. She was one of those women who take a delight in driving a man to the point where she all but hands herself over to him and then refuses him. That this had been happening over and over was proved by a remark of the headman of the quarter, the significance of which was missed absolutely by the court; it was further a matter of common knowledge in the quarter; but wife had been advised repeatedly to get rid of her sister, but would not do so. In the end, between sheer ungovernable sexual excitement and utter hatred of a woman who could persist in acting in this way after he had asked her repeatedly to end the matter either by completing it or else by leaving him alone, M. T. N. killed this woman; unfortunately her aunt rushed up

while he was "seeing red," followed by his own aunt; the former he killed, the latter he very nearly succeeded in killing. I am quite certain in my own mind that M. T. N. knew that he was doing an illegal thing; I am equally certain that he could not refrain from following the suggestion that he should kill this "woman." (ii) The killing of the woman's aunt and the attempted killing of his own aunt were but additional evidence of a state in which the man was unable to control his impulses; they are the acts of a person who is absolutely irrational.

I admit freely that in all of these cases the guilty person appears to be legally responsible for the acts which he committed, but in each case it has appeared obvious from the medical point of view that the guilty person was acting under an impulse which he could not control. The fact that there was considerable justification for this point of view lies in the event that in each case the prisoner was reprieved.

I admit likewise that I am dealing with more or less primitive peoples who are not necessarily fit to be submitted to the legal penalties of the common law of Great Britain; but it seems to me that there is a good deal more to be said about this matter than the merely legal aspect of the question, and that there is wisdom elsewhere than in the *McNaghten obiter dicta*. There are even times when it has seemed to me that many a thing which is illegal is right, and that many a thing which is legal is wrong.—I am, etc.,

HODGKINSON LACK.

University College, Rangoon, March 6th.

DR. YOUNG'S CANCER PARASITE.

SIR,—Recently Dr. James Young brought his "cancer parasite" to the Pathological Section of the Royal Society of Medicine, and it met with such a hostile reception at the hands of several members that we almost hoped to have heard the last of it. Why of all the speakers I should be singled out for a second reply (*BRITISH MEDICAL JOURNAL*, April 10th, p. 675), and why this particular occasion should be chosen, I do not know, unless it be that he wishes to show what a ferocious bully I am, and also to seize the opportunity of hitching his wagonette on to the elusive star of his fellow obstetrician. My contribution to the discussion was an account of a test of his parasite at the Cancer Hospital Research Institute, to which he had referred. This test was conducted at the instigation of a certain committee, who were well aware of the adverse opinions of numerous distinguished pathologists regarding Dr. Young's work, but who considered it desirable, for reasons I may not mention, to let him have a final try-out on as large a scale as he might wish under controlled laboratory conditions. I consented with considerable misgiving, knowing full well that no litigious person ever has a good word to say of a judge who may be compelled by the evidence to decide against him. I doubt if anyone was particularly interested in his views regarding the relationship between leukaemia, pseudo-leukaemia, and cancer; the only point was, would the organism produce anything that we could recognize as a malignant tumour?

Dr. Young therefore cultivated his parasite from material supplied at his request. The parasite, which on this occasion was a mould, one of the common contaminations with which all those with experience in the cultivation of tumours are only too distressingly familiar, was injected intraperitoneally into fifty mice in perfect conformity with Dr. Young's technique. We insisted on controls, which Dr. Young regarded as quite unnecessary, for we knew of the liability there is in some strains of mice to glandular hyperplasias that are not tumours and certainly not cancers, and we wished, further, to exclude the chance of spontaneous tumours, which are not uncommon in mice. Both sets of animals were examined from time to time for evidence of superficial cancer. None appeared in the mice injected with the parasite, but, as luck would have it, a spontaneous mammary carcinoma developed in one of the control animals. As the mice died, *post-mortem* examinations were made on them, but nothing in the least suspicious of neoplasia in any of the organs was visible to the eye of one who has had many years of experience in these examinations.

Dr. Young was, I believe, informed that the results of the test had not been in his favour, and on indirect inquiry

he ascertained that I had made no microscopic examination of all the organs, believing this to be useless. At the end of nine months he visited our laboratory, and he was good enough to express his sad sympathy with me at having so thoughtlessly destroyed the whole value of the experiment. Then I learned, for the first time, that it was "leukaemia" rather than cancer which his parasite had taken a fancy to produce. Recovering from the cruel blow I made haste to assure him that all was not lost, for eleven of his mice still remained alive and we could examine them for his lesion. But hope died when he told me that his experience had shown him that one never got the manifestations after the lapse of seven months. However, to please me, he would have a look at the organs of these mice. Greatly to his joy, two of them showed a certain amount of glandular hyperplasia in the region of the thymus gland, and still more to his surprise and satisfaction the livers of all of them exhibited microscopically his "leukaemic patches," on which he now set such store. He was not interested in, nor did he wish to see, the control animals. Had he been of an inquisitive nature he would have discovered that they also had the "leukaemic patches" in their liver. These appearances are indeed exceedingly common in laboratory mice. They consist of multiple small foci of lymphocytes, and bear no relation to tumours—or even to leukaemia.

That is the whole story, and it is only now disclosed since Dr. Young has so publicly appealed to Caesar against my narrow-minded and unfair prejudice. It only remains for me to say that the authorities whom he cites as having corroborated his work are not regarded as such by anybody I know.

I do not grumble at Dr. Young's poor opinion of me, nor at his controversial methods, but I am genuinely sorry that a man of his abilities should waste his time on his so-called "cancer parasite"—what my old teacher, Professor George Buchanan, would have described as "just a wee lump of dirt."—I am, etc.,

London, S.W.3, April 10th.

ARCHIBALD LEITCH.

THE KASTLE-MEYER TEST FOR BLOOD.

SIR,—I was much interested to read the article on the above subject in your issue of April 10th (p. 650). The test is better known under the designation of the "phenolphthalein test," and it is under this heading that it appears in textbooks of forensic medicine and chemistry. Peterson and Haines, in their textbook of legal medicine, consider the preparations of the reagents in great detail, and show that the zinc converts the phenolphthalein into phenolphthalin. Deléarde and Benoit¹ recognized blood in a dilution of 1 in 1,000,000 by this test, and later, Kastle² in a dilution of 80,000,000; the latter stated that in the event of a positive result being obtained oxidizing substances and salts of the heavy metals must be excluded by chemical means.

Von Czychlarz and Neustadt³ came to the conclusion that the test was unreliable, and found that healthy faeces gave a positive reaction after the oral administration of aspirin and other drugs—an important fallacy when one considers how common the use of aspirin is in this country, and that many of the garments sent for medico-legal examination may be contaminated in this manner.

It is a well known fact that when testing healthy faeces for occult blood by the benzidine test the faeces of a patient on a red meat diet will often give a positive result. Contrary to Dr. Glaister's findings, numerous observers have recorded a similar result with the phenolphthalein test. It is this extreme delicacy that prevents its use as a medico-legal proof of blood. As a means of selecting stains which may repay a more thorough examination it is a good test, ranking with the guaiac (Day's) and benzidine tests, but, as in the case of these latter, it cannot be accepted as a test for blood in a court of law.—I am, etc.,

MALARIA AND MULTIPLE NEURITIS.

SIR,—In the JOURNAL of September 12th, 1925 (p. 461), in a paper opening a discussion on the causation and symptomatology of multiple neuritis, by Dr. T. Grainger Stewart, as well as in a general review in a leading article on multiple neuritis, the word "malaria" does not once occur, and it might be suggested that the causation is included under the term "toxic" or "infective."

My experience of neuritis of malarial causation extends as far back as the later eighties of the last century—a period corresponding with that of M. de Lesseps's attempt to build the Panama Canal. At that time a considerable number of labourers from the West Indies working on the canal became victims of malaria, associated with multiple neuritis of so violent a type as to prevent moving about without help; among these were some Europeans, principally Frenchmen, who were advised by the physicians of those days on their arrival in France to consult Professor Charcot, and I was informed that they usually received a very courteous but humorous inquiry from him asking why these patients had been sent to him, as he could find nothing wrong with them; evidently a sea voyage (I will not add cuisine, as this might complicate matters) had effected the cure.

To say that this complaint is endemic here (Jamaica) might give too exalted an idea of its extent, but cases can always be found. The classic symptoms, as described by the patients themselves, are "pins and needles" and numbness and cramps in hands and feet, with dimness of vision.

Perhaps the most interesting point is the influence of climate on the treatment; cases arising on the sea coast rapidly improve on being transferred to the hills; on the other hand, should the victim acquire his trouble in the country, residence near the sea speedily gives relief.

It would be an unfortunate position for a newcomer to be called to a case of this and be ignorant of its origin.—I am, etc.,

Kingston, Jamaica.

G. F. D.

PHTHISIS A DISAPPEARING DISEASE?

SIR,—I should be glad to believe that we are on the right track, and I am grateful to Dr. Gibson for his pertinent criticism (March 20th, p. 547). But I fear that there is no fallacy if my argument be strictly adhered to.

I maintain that a statesman who would combat phthisis must concentrate on raising real wages—witness the amazing sequel to Peel's daring measures from 1842 to 1846, and the drop in mortality which followed the war wages. It is no refutation to say to me, urging that position after a prolonged rise in wages and consequent fall of mortality, that that fall proves me wrong. But that is what Dr. Gibson says when he quotes the figures of 1920-24. Those figures are part of my case: they reinforce my suggestion that the rise in mortality from 1914 onwards was due to lowered wages.

Real wages rose from the end of 1914, and continued generally high till 1921. British and foreign records abundantly show that 1917 was the last year in which the lowered pre-war wages would be operative, 1918 the first in which the enhanced wages would begin to act on the phthisis death rate. That this would fall in 1918 I foretold; that the rate would continue low till at least 1923 I said publicly at the British Medical Association meeting in 1920; 1917 is therefore the last year which Dr. Gibson ought to use against me; can he maintain his position on that condition? From the life-saving point of view his own figures show that from 1842 to 1895 there were 45.8, from 1896 to 1924, 20.5 lives saved per million each year. From the Registrar-General's reports I will add that from 1896 to 1911 the average rate was 22.1; from 1896 to 1917, 15 per million. The changes are too rapid not to have a basis in hard fact. I submit that in view of the emphasis which, by men like Koch and Newsholme, is laid on infection, and of the generous response in isolation facilities to obviate it, the only possible inference is that some factor is now at work to frustrate the increase of knowledge and communal care.

I am specially grateful to Dr. Gibson for the reference to "vital statistics," wherein I found that, like me though on somewhat differing grounds, Professor Karl Pearson had in 1911 read in the phthisis curve the threat of a rise in 1915. As against me, no curve which ends between 1918 and 1923 is a valid argument; and I respectfully submit that the very logarithmic curve with which Sir A. Newsholme combats Pearson's assertion that the rate of decline had slackened rather tends to show that Pearson was right. For before the war the male curve above diverges from, the female curve below tends towards, a straight line drawn to a record point after the war, conspicuously more in this century than the last. Only once—in 1913—does the male curve reach this line; repeatedly it passes under it in the last century. There are a hundred causes that may make an exceptional year for mortality, one among which is the considerable improvement in the age groups above that at which phthisis deaths are most frequent; and it is a startling reinforcement of my plea that at the end of the second decade of the century the only age groups that show an improved mortality are those of people born before 1900, except the group 0-1, for which everyone will readily admit special causes.—I am, etc.,

Bath, March 26th.

B. G. M. BASKETT.

NON-INFECTIONAL ARTHRITIS IN WOMEN.

SIR,—Dr. Cumberbatch and Dr. Robinson state that the object of their paper under the above heading in your issue of April 3rd (p. 612) is "to put forward the contention that there exist cases of arthritis occurring at either end of menstrual life which are not due to infection." They base this conclusion on the result of the empirical treatment of arthritis by diathermy. They tell us that when diathermy is applied to the pelvic organs arthritis due to gonorrhoea derives benefit, that arthritis due to other prostatic or uterine infections also receives benefit, and lastly, that benefit accrues if there is no infection at all in the pelvic organs. Clearly the curative action of diathermy is not due to its bactericidal effect. Yet the authors argue that because in their third class the pelvic organs are not infected the arthritis in these cases must also be non-infective. They have already shown that the presence of microbes is quite immaterial; therefore either their conclusion falls to the ground, or if it stands it would be equally valid to say that all arthritis cured by diathermy is non-infective, which, in the case of gonorrhoeal rheumatism, is a *reductio ad absurdum*.

As in certain cases there are no pelvic microbes to kill, another explanation of the diathermy effect has to be found. The authors suggest that the stimulation of the ovarian hormone must be the cause of the improvement, as that, they imply, is the only way in which the diathermy could act. The renewal of the menstrual flow supports their view. If, then, an increase of ovarian hormone results in cure, hormone deficiency must be the cause of the arthritis. So the argument runs. This, surely, is equally fallacious. To quote Sir James Berry in another discussion about iodine deficiency in goitre: "It would be just as fair to argue that quinine deficiency is the cause of malaria." Again, if the diathermy stimulates the hormone in one class of arthritis, it presumably does the same in every class. It is then quite as likely that stimulation of the gonadal secretion was the effective factor in the cure of the gonorrhoeal rheumatism. In point of fact, the beneficial effect of the diathermy has no more bearing on the microbial hypothesis than has the effect of any other non-specific cure, such as light treatment, or massage, or Epsom salts.—I am, etc.,

H. WARREN CROWE.

Harrogate, April 5th.

THE FACTS OF SEX.

SIR,—I observe in your issue for March 27th a review of M. Paul Bureau's book, *Towards Moral Bankruptcy*. The reviewer, while appreciative of the author's ethical earnestness, yet clearly does not agree with his diagnosis of the social disease, probably not with his prognosis either, and certainly not with his proposed remedies. In reference, for example, to the author's condemnation of sex teaching in schools, your reviewer says, "We do not accept his belief

that ignorance is the foundation of elasticity." In other words, the reviewer, in consonance with what is certainly a growing body of public opinion, holds that "the facts of sex" should be taught in schools to the young generation.

Will you let me say that I believe a fallacy to underlie this contention? The contention is based on an assumption—namely, that the facts of sex are known; and, further, that these are essentially of an anatomical and physiological order. This assumption I—in common, I think, with M. Bureau, and perhaps with more others than your reviewer may wot of—would dispute. If it be answered that, while there may be other aspects of sex, these do not belong to the realm of "science," then I would suggest that the sooner science begins to realize its limitations the better; if it goes on much longer proclaiming that life is nothing more than anatomy and physiology (with, of course, a little chemistry and physics thrown in), M. Bureau's prognosis will quite likely prove correct.

I maintain, then, that it will be time enough to talk about teaching "the facts of sex" to children when we know them—in their essence—ourselves.—I am, etc.,

Edinburgh, March 27th.

A. J. BROCK.

TUBERCULOSIS AND PREGNANCY.

SIR,—May I amend your report of the joint tuberculosis meeting at Cambridge (April 3rd, p. 629) respecting the opinions attributed to me as to the effect of marriage and pregnancy on tuberculosis?

In 125 women I noted that marriage alone—that is, without child-bearing—left 60 per cent. of patients unaffected; 26 per cent. were better in health, 14 per cent. worse. Now 15 to 20 per cent. of patients may be expected to deteriorate in any period of one or two years, so we must conclude that marriage alone has, if anything, a beneficial effect on tuberculosis.

Pregnancy.—Out of 423 pregnancies in 237 women, 53 per cent. had no effect, 16 per cent. improved the patients' health, 31 per cent. made them worse.

Parturition.—442 labours in 240 patients showed 32 per cent. of patients unaffected, 19 per cent. better, and 49 per cent. worse.

The worst type of case was that in which the first clinical onset of disease occurred during pregnancy or after parturition; of these patients about half have died.

An observer may well be led astray by the consideration of a small number of cases; the figures just given suggest that although widely different effects may be noticed, parturition must, on the whole, be considered a danger to tuberculous women.

The evidence appears to be definitely against artificial interference with pregnancy, for 50 per cent. of cases with miscarriages were made worse—practically the same figures as for full-term labours; and to me such a measure as Caesarean section, advocated by Dr. Marshall, seems most undesirable.

It must be admitted that there are no inflexible rules in medicine, and I have no figures showing the effect on patients of artificial termination of pregnancy by Caesarean section or any other method.—I am, etc.,

Paignton, Devon, April 4th.

E. WARD.

INSURANCE AGAINST ERRORS OF LOCUMTENENTS.

SIR,—A letter from the Medical Defence Union which appeared in your issue of March 27th has led to inquiries as to the attitude adopted by the London and Counties Medical Protection Society where actions are brought against principals who are members of the society in respect of the professional work of locumtenents who are not members of the society. Several years ago a case of the kind came before the council of the London and Counties Medical Protection Society, and it was undertaken on behalf of the member, although the locumtenent from whose work the claim arose was not a member of the society. This did not involve any departure from the rule that one subscription should not be allowed to cover the work of two or an indefinite number of practitioners associated as principals and assistants. The society was advised

that a principal is not legally liable for the default of a locumtenent, provided he has used proper care to make sure that the locumtenent is properly qualified and competent. The case referred to never went into court, but the society has ever since undertaken any cases of the kind, and intends to do so.

The legal position is not as certain as could be wished, but the fact that cases in which the London and Counties Medical Protection Society has challenged legal proceedings have not resulted in proceedings being carried to trial by the other side seems to indicate that the view taken by the society of the legal position was well founded. When a case of the kind does go to trial it is more than probable that it will have to be taken to the House of Lords if a final decision is to be obtained, since the cases bearing on the question in the Court of Appeal are somewhat conflicting.—I am, etc.,

HUGH WOODS,

General Secretary, London and Counties Medical Protection Society, Ltd.

London, W.C.2, April 12th.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons resumed its sittings on April 13th. The House of Lords does not reassemble till April 19th. The principal business of the Commons this week has been further consideration of the Economy Bill. The Judicial Proceedings (Regulation of Reports) Bill came up for second reading on April 16th. April 15th was appointed as the day on which a Standing Committee would consider the Midwives and Maternity Homes Bill which Dr. Fremantle has introduced. The Select Committee on the Registration of Nursing Homes was summoned to meet later on April 15th, and will also sit on April 20th. The second reading of the Bethlem Hospital Bill was moved unsuccessfully on April 13th, and is now put down for May 10th, by which time the notices of objection now entered against it may be withdrawn. The Report stage of the Registration of Births and Deaths Bill is down for June 6th.

R.A.F.M.S.

On April 13th the Secretary for Air told Mr. Hayes that the total cost of the headquarters medical organization of the Royal Air Force was £13,026, including clerical staff. The fullest use was made wherever possible of naval and military hospitals for Air Force patients. There were only three separate Air Force hospitals in this country, and of these two were situated at stations at which large numbers of Air Force personnel were concentrated, but which were remote from any hospitals administered by the other services; the third was a small hospital, with only twenty-five beds, primarily intended for officers suffering from flying disabilities. Conversely, the existence of Air Force hospitals in Iraq and Palestine eliminated the need for maintaining British or Indian army hospitals for the imperial and local ground forces in those countries. During 1925 the admissions of personnel (including families) of the Royal Air Force to naval and military hospitals numbered 3,227, while during the same period there were upwards of 3,000 admissions of personnel of the navy, the British and Indian armies, and local forces in Iraq and Palestine to Air Force hospitals. The possibility of further co-ordination between the Air Force medical service and the medical services of the Navy and Army (as well as the Ministry of Pensions) was kept continually under review by a Joint Medical Services Committee, set up in accordance with the recommendations made by the committee presided over by Sir A. Mond. This joint committee advised on: (1) Important questions of medical policy, such as the construction of new hospitals. (2) Provision of facilities for common training. (3) Specifications for the supply of medical stores and appliances. (4) The use of Navy, Army, and Air Force hospitals for the accommodation of disabled pensioners. (5) All matters in respect of which economies might be effected by co-operation of the four departments. Regular meetings had been held and the committee had been successful in securing the closest co-operation and co-ordination of medical work in the three services.

Economy Bill.

Consideration of the Economy Bill was resumed in Committee. On Clause 2 of Part I (which deals with national health insurance and amends the Act of 1924) Mr. R. J. Davies moved an amendment to omit the provision that any expenses incurred by the Minister of Health in connexion with medical benefit should fall on the approved societies. He said the purpose of the amendment was to challenge the power of the Minister who made agreements on behalf of the insured population with general practitioners acting as panel doctors. The Opposition was not satisfied that the Minister had so far made, or would in future make, the best bargain possible with the doctors in favour of the insured persons. There was a great deal of criticism, not of the attitude of the

Minister of Health, but of the actions of the medical profession, in giving treatment to insured persons. For his own part, on the whole he thought that the panel doctors had done their work admirably under the State insurance scheme. He believed, however, that the doctors had been paid handsomely for their work and that the Minister had not been at all stingy with them. The Minister should pay more attention to the opinions of the approved societies, and his power to veto their proposals should be taken away. The cost of administration ought to fall on the Exchequer.

Sir Kingsley Wood, Parliamentary Secretary to the Ministry of Health, said that the provisions of Clause 2 of the bill were designed to carry out the recommendations of the Royal Commission on National Health Insurance. The Commission came unanimously to the conclusion that medical benefit should be paid for out of the funds of the approved societies. The whole of the clause had received the support of the Consultative Council.

Mr. E. J. Davies asked whether the support of the Consultative Council in regard to Clause 2 of the bill was not contingent on the omission of Clause 1. Sir Kingsley Wood said that that was not so. The Treasury would save, by the proposal, 3d. per member per year in respect of the cost of regional medical officers and of the central index register.

The amendment was rejected, and further debate on the bill followed.

Registration of Nursing Homes.

The Select Committee on the Registration of Nursing Homes resumed at the House of Commons on March 30th. Sir Cyril Cobb in the chair. Dr. J. W. Bone, Dr. Lord, and Dr. Fothergill were examined together in respect of the evidence submitted by the British Medical Association. The Association, in a written memorandum, recalled that the Representative Body of the Association, at the Annual Meeting at Bath last July, considered the Nursing Homes Registration Bill then lately introduced into the House of Commons by Mr. Gerald Hurst, and had instructed the Council actively to oppose any such bill which did not comply with three conditions laid down by the Representative Body. The first condition was that the bill should provide for representation of the local medical profession on any local committee formed by the authority for supervising nursing homes. The Association held that delegation to such local committees should be compulsory, and that doctors and nurses should sit on all such committees. The second condition was that the bill should secure that all case sheets and medical records were strictly confidential, access being only permitted to the medical profession. The third condition was that the bill should not apply to premises under the control of a registered medical practitioner. The memorandum said that the object of receiving patients, often border-line patients, into a doctor's house was to provide for them the privacy and atmosphere of a home of a non-institutional character, whilst ensuring the care, supervision, and treatment of a doctor. There were doctors who took into their private residences several patients of a special class, such as drug addicts, border-line mental cases, or neurasthenics. These patients came purely of their own volition, were often difficult to deal with, and required almost daily to be tactfully handled. If doctors had to have notices outside their houses denoting they were nursing homes, and had to display regulations inside, they would probably discontinue this class of business. The Association held that this would be contrary to the interests of the public. It also felt that registration would be detrimental to hospitals conducted by groups of medical men and to the nursing homes for private patients which were increasingly provided in connexion with voluntary hospitals.

Dr. Bone, answering Sir Cyril Cobb, said that the records of patients were never open to inspection. A member of the Association who had a surgical home in the North of England had told him that if a locally prominent person were in his home and the records were open to inspection by a committee, it would be almost impossible to prevent that patient's medical record from becoming locally known.

Miss Wilkinson asked whether the demand for the exemption of any home run by a doctor was not a little wide.—It is a little wide, but these three points were insisted upon at our meeting at Bath, and we are instructed to oppose any bill which does not meet them.

Dr. Fothergill explained that the medical profession was under the discipline of the General Medical Council. "Our houses," he said, "are where we live with our families, and by inspection the family aspect, so valuable for patients, would be destroyed. We are also inspected in our houses by the Board of Control."

Sir Cyril Cobb remarked that the General Medical Council did not suspect save upon complaint. There might be cases of ill treatment of patients without complaint. Take the case of a sick person in a doctor's house who was, or thought he was, ill treated, and who was too ill to get away. Did the witnesses say that without inspection that sick person must be all right? Dr. Fothergill replied that the patient's friends or relatives would be in touch with the case. Dr. Bone remarked that where a nursing home was conducted by a group of medical men a committee of management would ensure good conduct. He instanced nursing homes thus maintained in association with the Bedford County Hospital and St. Thomas's Hospital. Mr. Gerald Hurst, a member of the Committee, suggested that such homes would have been excepted from the 1925 bill.

The Chairman then asked what was the Association's objection to the inspection of nursing homes by registered nurses. Dr. Fothergill said the homes would be under the control of registered nurses and that the matrons in regard to their conduct would be under the General Nursing Council. What required inspection was the structural condition of the homes, and also whether the home was

staffed by "cheap girls" in nurses' caps. A woman would have to live on the premises before she could say that the nursing given was adequate. If a woman inspector walked into a nursing home, buttonholed nurses on the stairs, and cross-examined everyone down to the kitchen-maid, they would have chaos within half an hour in the best conducted nursing home.

The witnesses agreed that some homes were poorly staffed with too many probationers and that fees might be too large. Dr. Bone gave reasons why the inspection of maternity homes could be regarded as a different question from that of nursing homes in general. Asked if there was any general opinion in the British Medical Association in support of registration, Dr. Bone said that the Association was in favour of registration, but had no evidence of any special need for it.

Dr. Shiels asked if the witnesses would favour the appointment of a special inspecting committee of the British Medical Association or General Medical Council, to undertake the supervision of nursing homes run by doctors, conducted in their own home or not.

Dr. Bone said that at present they were concerned with getting rid of the objections in the bill which came before Parliament during last year. Later they might very well take the suggestion of Dr. Shiels into consideration as doctors were always anxious to manage their own affairs.

Miss Rundle, secretary of the College of Nursing, said training nurses were in favour of registration, on the ground that the public was insufficiently protected; they believed the public was dissatisfied with things as they were. The registration and inspection of nursing homes would lead, she thought, to a higher standard of qualification in nurses. All homes should be subject to some form of registration.

The Committee adjourned till April 15th.

Sight-testing Opticians.—On April 13th Sir Kingsley Wood informed Mr. Kelly that for reasons explained by the Minister of Health to the recent deputation from the Joint Council of Qualified Opticians, which waited on him in regard to sight testing, the Government did not propose to take any action in the matter. The Government was not prepared to grant any facilities for the passage of the proposed bill for the registration of optical practitioners.

Obituary.

J. W. F. RAIT, M.B., B.S. LOND.,

Lieut.-Colonel I.M.S. (ret.).

We have to announce with much regret the death of Lieut.-Colonel John Walter Forbes Rait, Indian Medical Service (ret.), which took place at his home in Radlett Herts, on April 9th, a few days after his 53rd birthday. He was born in Dublin on April 5th, 1873, the son of Henry Rait, and was educated at University College, London, graduating as M.B. Lond. in 1896, and also taking the L.S.A. in 1897. Later on he took the B.S. degree in 1906, and obtained the diploma in tropical medicine and hygiene, with distinction, at the London School of Tropical Medicine in 1909. At the Army Medical School, Netley, he won a gold medal in surgery, and entered the Indian Medical Service as lieutenant on January 28th, 1898. He reached the rank of lieutenant-colonel on July 28th, 1917, and retired on January 24th, 1919. After a few years of military duty, during which he served in the China war of 1900, receiving the medal, he entered civil employ in Bengal, and put in the rest of his service in that province. His appointments included those of resident surgeon at the Calcutta Maternity Hospital, surgeon to the Presidency General Hospital, Calcutta, and surgeon superintendent of the Campbell Hospital and Medical School.

Since his retirement from the Indian Medical Service Colonel Rait had taken a warm and active interest in the central work of the British Medical Association, and was a regular attendant at Council and committee meetings. He had been a representative of the grouped Indian Branches on the Council since 1923, and at the time of his death was a member of the Dominions Committee, the Naval and Military Committee, and of the special committee set up in connexion with the Royal Commission on the Superior Civil Services in India. He was a member of the Journal Committee in 1924-25.

The claims of medical charity made a special appeal to his generous nature, and last year, in conjunction with Mrs. Rait, he made a gift to the Association of certain shares and investments with the object of creating a fund the income from which should be applied by the trustees to benefiting members of the medical profession in need of relief or assistance so that they might be able, if possible,

to continue exercising their profession. The trustees appointed under a trust deed, drawn up by the solicitor for the purpose of carrying out the wishes of Colonel and Mrs. Rait, are the Chairman of Council, the Chairman of the Representative Body, and the Medical Secretary. It was the desire of the donors that the fund should in no way run counter to existing medical charities, and the trustees were given unlimited powers to distribute it for the benefit of individual members of the profession or their dependants as they might think fit. The Chairman of Council, Sir Robert Bolam, in announcing this gift to the Council last June, said that he had suggested to Colonel Rait that it would be suitable to associate such a very excellent departure with his own name and that of his wife, who were the benefactors, but with characteristic modesty Colonel Rait had declined, and had asked that it should receive the name of the "Sir Charles Hastings Fund," after the founder of the Association. The donors expressed the hope that the fund might be augmented from other sources, thereby adding to the means of the Association for giving help in grave emergencies. This benefaction, gratefully accepted by the Council, is recorded on one of the panels in the Council Chamber in the Association's new House.

The funeral service was held on April 13th at Radlett. The Council of the British Medical Association was represented by Sir Richard Luce, K.C.M.G., M.P., and the headquarters staff by Dr. C. Courtenay Lord, Assistant Medical Secretary. The West Hertfordshire Division of the Association was represented by its honorary secretary, Dr. C. D. Hatriek of New Barnet.

MARION VAUGHAN, L.S.A., D.P.H.CAMB.

WE regret to have to record the death on March 29th of Dr. Mariou Vaughan. She continued her work up to the last. Her death was in no way anticipated, except in the fears of a few intimates, who knew the state of her health and the necessity of an approaching operation.

Dr. Marion Vaughan (*née* Hunter) received her early education in America, and later studied medicine at the London (Royal Free Hospital) School of Medicine for Women and also at King's College. She qualified in 1894, and obtained the D.P.H.Camb. in the following year; after holding several appointments at the Royal Free Hospital she became a plague medical officer in India and Egypt, 1898-99. Later on she established herself in general practice in South Street, South Kensington, where her ability, industry, and attractive personality brought her a large practice. In 1909 she married Mr. Percy Cecil Vaughan, barrister-at-law, and enjoyed the happiness of a complete comradeship, which was only severed by the war, when her husband lost his life while on active service. Dr. Vaughan was medical officer to the Anglo-French Military Hospital in France. Last year she helped to start the artificial sunlight clinic in Hertford Street. But the work in which she was greatly interested, and by the continuation of which she would hope to be remembered, was the establishment of an infant welfare clinic in West Islington. In 1916 she herself collected a considerable sum of money, and started a scheme of visiting to prepare the way by interesting the parents. At the first consultation held by Dr. Vaughan fifteen mothers and babies were seen. The need for the work and its immediate success were shown by the fact that the number of attendances during the first year amounted to 2,500. The work grew very rapidly, and in spite of the claims of her private practice Dr. Vaughan devoted time and untiring zeal to its promotion. To such an extent were her efforts rewarded that in 1925 eight clinics a week were held, and the total attendances were 18,000. Not only was preventive work undertaken at this centre, but a ward for ailing babies was established. During her last illness the future of the centre was constantly in her thoughts, and it was her great wish that the work should continue.

Dr. ALEXANDER JOHN FINLAYSON, who died on March 4th, was the elder son of Mr. Alexander Finlayson of Loch Carron, in Ross-shire, and received his early education at

Dingwall Academy. In 1916 he left Dingwall, joining the 7th Gordons at Aberdeen. He served in France with the 51st Division, and was for a period with the Army of Occupation on the Rhine. After demobilization from the London Scottish in 1920 he entered Glasgow University as a medical student, where he was a prominent member of the athletic club; and in the shinty section, of which he was for some time secretary, he received a "blue" in 1922. He graduated M.B., Ch.B. in April, 1925, after which he practised for a short time in his native village, returning to Glasgow in July as assistant to Dr. Campbell MacLean, who writes: "With the energy and buoyancy so characteristic of him, he threw himself wholeheartedly into his work, and soon showed that his reputation for thoroughness was well earned. His patients found him more than a physician, and mourn him as a friend. The high esteem in which he was held was shown by the large attendance of college associates and patients at the funeral service. Deep sympathy is felt for his father, brother, and sisters."

We regret to record the death of Dr. GEORGE EDWARD D'ARCY ADAMS, at Bussage, Brimscombe, Glos., on March 20th, in his 80th year. He was the eldest son of the late Dr. George Adams, who practised for many years at Nailsea, Somerset. Dr. D'Arcy Adams received his medical education at King's College, London, and Aberdeen, and graduated M.B., C.M. in 1867. He proceeded M.D. in 1874, and obtained the D.P.H.Camb. in 1881. For several years he held the appointment of surgeon on the Estancia San Jorge, Montevideo, Uruguay, but owing to his father becoming ill he returned to England and practised with him until 1880, when he purchased a practice in Maida Vale, London, at the same time being appointed medical officer to the Paddington Provident Dispensary and Kilburn General Dispensary. Later he joined Drs. Webb and Walker, who were in practice in the same district. Dr. Webb died and Dr. Walker retired, and Dr. Harold Darwin Hey subsequently joined him in partnership. Dr. D'Arcy Adams retired in 1919, after thirty-nine years in arduous general practice. He was a very well read man, familiar with many European languages, including French, German, Norwegian, Spanish, Italian, and Portuguese; in his earlier days he translated articles in foreign medical magazines for English publications. His favourite hobby was sketching, in which he took great delight. He was greatly beloved by his patients and friends, alike for his courtesy, generosity, and unselfish devotion to his work. He leaves a widow, three sons (of whom two are members of the medical profession), and two daughters, with whom much sympathy is felt. He was a member of the British Medical Association.

Dr. FREDERICK WILLIAM AXHAM, who died on April 8th, at the age of 86, had been a central figure in the recent agitation fostered by certain newspapers against the General Medical Council. He took the diploma of M.R.C.S. Eng. in 1861 and that of L.R.C.P. Edin. in 1867; he had been at one time medical officer of the workhouse of the Westminster Union, and afterwards became associated with Mr. (now Sir) Herbert Barker, for whom he gave anaesthetics. The circumstances which led to his removal from the Medical Register were fully reported at the time in our columns, and were summarized in a letter from the Registrar of the General Medical Council published in the *Times* of December 30th, 1925. In the course of his letter the Registrar stated that during the hearing of an action for damages brought by a patient against Mr. Barker in 1911 it appeared that Dr. Axham was employed by him to assist him in the treatment of the patient by giving an anaesthetic. The report of the trial was brought to the notice of the Council by the statutory declaration of a competent complainant, and an inquiry was ordered; as a result Dr. Axham's name was erased from the *Medical Register* in May, 1911, and subsequently the Royal College of Surgeons of England removed him from membership and the Royal College of Physicians of Edinburgh suspended his licence. The Registrar of the General

Medical Council stated: "I am informed that his association with the unqualified practitioner continued for some ten years, but though this ceased some five years ago, only this autumn did he take steps to have his name restored." Dr. Axham was informed that the Council, until he was again in possession of a registrable qualification, had no power to take any action in his case. Subsequently the Royal College of Physicians of Edinburgh did restore his diploma (in January last), and it was understood that the Council would consider his case at its meeting in June. The Executive Committee of the Council, though pressed to do so, did not consider it expedient to call a special meeting of the Council to consider the case.

Universities and Colleges.

UNIVERSITY OF LONDON.

The following have been recognized as teachers of the University in the subjects and at the institutions indicated:

Guy's Hospital medicine, women, Dr. T. J. Hoskin (medicine).
Mr. Frank Cook medicine, women, Dr. T. J.
Mr. Oswald G. Mc medicine, women, Dr. T. J.
London (Royal) medicine, women, Dr. T. J.
Hoskin (medicine) medicine, women, Dr. T. J.

King's College Hospital Medical School.—Dr. H. B. Day (forensic medicine), Mr. H. A. Colwell (radiology).
National Institute for Medical Research.—Professor Leonard Hill (physiology), Captain S. R. Douglas (experimental pathology and bacteriology), Dr. H. H. Dale (physiology, pharmacology, and biochemistry).

It has been resolved to institute, in accordance with the regulations on University titles, Chairs of (1) Bacteriology and Immunology and (2) Epidemiology and Vital Statistics, both tenable at the London School of Hygiene and Tropical Medicine.

Sir Cuthbert S. Wallace, K.C.M.G., C.B., has been appointed one of the representatives of the Royal College of Surgeons of England on the Senate for the remainder of the period 1925-29, in succession to Mr. James Sherren, C.B.E., resigned.

The ceremony of Presentation Day, to be held in the Royal Albert Hall on May 12th at 3 p.m., will be followed by a service at Westminster Abbey at 5.30, when the Right Rev. F. T. Woods, Lord Bishop of Winchester, will preach. The graduation dinner will take place in the evening at 8, in the Merchant Taylors' Hall, Threadneedle Street.

A course of three lectures on the nature and functions of the fasciae of the human body will be given by Dr. J. Kay Jamieson, Professor of Anatomy, University of Leeds, at King's College on Fridays, April 30th, May 7th and 14th, at 5.30 p.m.

Applications for the Chair of Physiology, tenable at St. Bartholomew's Hospital, salary £1,000 a year, must be sent in to the Academic Registrar by May 20th.

A course of lectures on mental deficiency, supplemented by a course of clinical instruction, will be given at the central buildings of the University from May 31st to June 5th. Full particulars can be obtained from Miss Evelyn Fox, c/o the University Extension Department, University of London, S.W.7.

The election to Beit Fellowships will take place on or about July 15th. Forms of application must be sent in by April 19th; all information may be obtained by letter only from the Rector, Imperial College, South Kensington, London, S.W.7.

UNIVERSITY OF GLASGOW.

The following candidates have been approved at the examination indicated:

FINAL M.B., CH.B.—W. Allan, J. Anderson, May Anderson, W. Anderson, R. D. Balfour, D. K. Ballingall, F. C. Bamford, A. F. Beaton, W. Beattie, A. Bernard, G. G. Blair, W. S. Boyle, J. Brown, J. S. Brown, Katherine R. Brown, Winifred Buchanan, H. Burt, Ada M. Cameron, J. Campbell, Rina B. Campbell, J. Chalmers, D. P. Cothbertson, J. Denholm, Mary E. Devine, A. S. Dick, H. A. A. Doherty, J. Durie, T. C. Findlay, W. H. Fletcher, F. J. Ford, R. S. France, J. A. Fraser, J. Fryer, C. S. Garrett, N. C. Gellatley, Elizabeth H. Gemmell, R. G. Gemmell, Marion W. Gray, R. C. Grieve, Mary A. Griffin, E. W. Graham, W. Haddow, R. Hall, L. E. Hamilton, Margaret C. P. Hamilton, A. Hanton, W. C. Harris, Constance E. M. Herbertson, A. D. Hutchison, J. Innes, M.A., P. G. E. Jolley, R. S. Kerr, D. Kilpatrick, J. L. Kydd, S. I. A. Laidlaw, J. S. Laurie, D. D. Lawson, R. G. Lendrum, W. H. Lindsay, W. A. Lochhead, Miriam K. McAllum, A. McCracken, J. N. McCully, D. Macdonald, G. Macdonald, W. McLeod, A. McManus, A. McMurtry, W. G. MacNaughton, I. H. H. McNeill, Olive C. H. C. MacRae, T. G. H. Martin, A. Mellick, F. G. Meyer, R. B. Miller, Agnes Moncrieff, T. M. Montford, J. Morrison, W. A. Murray, Mary M. E. Mycroft, Agnes S. Nutt, T. S. O'Neill, E. G. Oastler, D. C. Orr, J. S. Orr, D. Prentice, M. S. Purvis, Florence Read, Anna M. Robertson, Catherine Ross, W. Scobie, J. Sharpe, W. Shirkey, A. F. Shirras, T. Sim, J. Stewart, J. H. Thomson, A. Walker, Janet B. C. Wagh, W. Whitley, Helen M. Wightman, W. Wilkie, E. A. Wilson.

* Distinction in surgery.

† Distinction in midwifery.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

At the monthly business meeting of the College, held on April 9th, the following candidates, nominated on January 1st, were duly elected Fellows of the College: Robert Henry Micks, M.D., Andrew Hope Davidson, M.D.

The following candidates, who had passed the Final Conjoint Examination, were admitted Licentiates in Medicine and Midwifery of the College:

L. P. Burns, M. Cusack, C. E. Eccles, W. P. Fowler, M. Gallagher, R. J. Gubbins, Kathleen Keirans, J. Lenten, J. Maguire, J. McCarren, M. McGreal, T. O. B. O'Brien, M. Ryan.

The President of the College was nominated a delegate to be present at the celebration on June 10th and 11th of the bicentenary of the foundation of the Faculty of Medicine in the University of Edinburgh.

Medical News.

THE annual meeting of the British Science Guild will be held at the London Mansion House on Thursday, April 29th, at 4.30 p.m. Lord Askwith, president, will be in the chair, and papers will be read by Sir Richard Redmayne on the coal industry, by Dr. E. F. Armstrong, F.R.S., on dyestuffs, and by Captain P. P. Eckersley on broadcasting and the electrical industry. Cards of invitation can be obtained from the Secretary of the Guild, 6, John Street, Adelphi, London, W.C.2.

THE annual meeting of the Royal Medical Benevolent Fund will be held at 11, Chandos Street, W.1, on Tuesday next, April 20th, at 5 p.m., and not April 22nd as previously announced.

AT the meeting of the Society of Public Analysts on April 7th Dr. J. F. Tocher reported the results of his continued study of the total quantity of the constituents of milk given, on an average, by an individual cow at each milking, and of the relationship of the casein to other factors. He found that the percentage of butter-fat tended to decrease slightly with increasing yield per milking, but that the total amount of butter-fat (and also of solids not fat) increased proportionately with increased yield.

A CONGRESS of spas in the centre of France will be held at Clermont on June 6th under the presidency of Professor Castaigne.

AT the next social evening of the Royal Society of Medicine (Monday, May 3rd) Sir Humphry Rolleston, Bt., M.D., will give an address, at 9.30 p.m., on some worthies of the Cambridge Medical School. The library will be open and various objects of interest will be exhibited. Owing to the popularity of those evenings it has been found necessary to provide that guests, unless accompanied by a fellow, member, or associate, must be armed with a card of invitation, which can be obtained by fellows, members, or associates from the Secretary of the Society, 1, Wimpole Street, W.1.

WE have on previous occasions referred to the publication by the Health Section of the League of Nations of a series of handbooks dealing with the organization of the public health services of different countries. A report in one volume has now been issued on the progress made in public health in twenty European countries, Canada, and the United States of America. It contains statistics published as recently as the early part of last year, and particulars of health legislation. The information as to each country is classified under such headings as campaigns against tuberculosis and venereal diseases, mortality and birth rates, control of food and drugs, hospitals, and medical education. The volume has a good index and is in fact an up-to-date gazetteer of the health conditions of the various countries dealt with.

PROFESSOR R. J. S. McDOWALL will deliver a course of lectures on physiology applied to hygiene at the London School of Hygiene and Tropical Medicine, beginning on May 7th. The course is primarily intended for students preparing for the diploma in public health, and will deal particularly with the physiological basis of public health work; no fee will be charged to D.P.H. students. The syllabus of the lectures may be obtained from the Secretary of the London School of Hygiene and Tropical Medicine, 23, Endsleigh Gardens, W.C.1.

THE late Mr. J. Basil Hall, M.Chir., F.R.C.S., of Bradford, past-president of the British Medical Association, has left estate valued at £29,823.

ON his retirement from practice Dr. Gardiner W. Trouton was presented by his friends with a grandfather chime clock, an easy chair, and a silver salver, as a token of their gratitude and affection after thirty-one years' practice in Rotherfield.

UNDER the will of the late Mr. Alfred Shuttleworth of Lincoln the Lincoln County Hospital receives £4,000 and the Lincoln General Dispensary £1,000.

THE third National Congress of Argentine Medicine will be held at La Plata in July, under the presidency of Dr. Carlos S. Cometto.

It is announced in the *Medical Journal of Australia* for March 6th that the John Irvine Hunter Memorial Fund has now reached the sum of £1,956. Dr. Hunter was Professor of Anatomy in the University of Sydney, and died in London, while on a visit to this country, on December 10th, 1924, at the early age of 26. A memoir of his brilliant career was published in our issue of December 20th, 1924, at page 1181.

DR. C. HARTLEY DURRANT, Chief Medical Officer of the St. Kitts-Nevis Medical Service, has been appointed a member of the Legislative Council of the Presidency of St. Christopher and Nevis.

DR. GEORGE A. PRUE, who retired in January last from the office of medical electrician to the Dundee Royal Infirmary owing to impaired health, has been publicly presented with an inscribed silver salver, a grandfather clock, and a cheque for £1,120, in recognition of his self-sacrifice in the study and practice of radiology.

WE have received a copy of the first issue for 1926 of *Internacia Medicina Revuo*, the organ of the International Esperantist Medical Association, edited by Dr. Vanverts of Lille, which is now in its fourth year. The issue contains articles on the control of venereal diseases in the United States by Dr. Ulman of Prague, immunotherapy and protein therapy by Dr. J. Kozrzewski of Cracow, and the present economic state of medicine by Dr. Leon Zamenhof of Warsaw; abstracts from current literature; and congress intelligence.

THE first two monthly issues for 1926 of the *Philippine Journal of Science* have been combined into one volume, and contains an account of dengue by Lieut.-Colonel J. F. Siler and Majors Milton W. Hall and A. Parker Hitchens of the Medical Corps of the United States Army. The subject-matter, which is illustrated by eight plates and twenty figures in the text, deals in detail with the history, epidemiology, the mechanism of transmission, the etiology, clinical manifestations, immunity, and prevention of this disease. The British agents for this journal are Messrs. Wheldon and Wesley, Ltd., 28, Essex Street, Strand, W.C.2.

WE have received specimen copies of the *Zeitschrift für das gesamte Krankenhauswesen*, which is the continuation on a more extensive scale of the *Zeitschrift für Krankennsstalten*. The journal, which is issued fortnightly under the editorship of Professor A. Gottstein, assisted by Drs. P. Weinstock and J. Wirth, is, as its subtitle indicates, the organ of the leading administrative officials of public hospitals; and contains original articles, abstracts from current literature, society intelligence, and reviews relating to the erection, equipment, and administration of hospitals.

WE learn from the *Times* that a number of bonesetters from the North of England and from London met in Scarborough on Easter Monday and resolved to establish a British Bonesetting Association. A council of five bonesetters, of ten years' standing, was appointed to arrange for a register of bonesetters, of whom it is estimated that there are 200 in the country. Persons so registered must have been in practice as bonesetters for five years and must devote the whole of their time to that occupation. Mr. John Blackburn of Doncaster was elected president of the association, which is stated to be quite distinct from the British Osteopathic Association.

THE Fellowship of Medicine announces that Mr. H. J. Paterson will give a clinical surgery demonstration at the London Temperance Hospital on April 22nd at 2 p.m., free to members and general course ticket-holders of the Fellowship. The Bellingbroke Hospital will hold a course in medicine, surgery, and the specialties from April 19th to May 1st. Also beginning on April 19th is a week's intensive course in proctology at St. Mark's Hospital and a two weeks' course in urology at St. Peter's Hospital. From May 3rd to 22nd a special course in medicine, surgery, and gynaecology will be held at the Royal Waterloo Hospital. The Central London Throat, Nose, and Ear Hospital will provide an intensive course in laryngology, rhinology, and otology from May 3rd to 22nd; the course includes clinical and operative parts, which may be taken separately. The Royal Westminster Ophthalmic Hospital will hold an afternoon course from May 3rd to 22nd, consisting of clinical work and special demonstrations thrice weekly. A comprehensive course in venereal diseases will be given at the London Lock Hospital from May 3rd to 29th. At the Mandslay Hospital there will be a course of lectures and demonstrations in psychological medicine from May 3rd to 28th, an abridgement of the diploma course now in progress there. From May 9th to 22nd the Infants Hospital will hold a special course in infants' diseases for medical officers of welfare centres and others interested. The course is limited to fifteen, and will include lectures, clinical demonstrations, and visits to various institutions. Copies of all syllabuses may be obtained from the Secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

QUERIES AND ANSWERS.

HYPERPYREXIA.

DR. T. J. O'MEARA (Skibbereen) writes in reply to Dr. H. L. McCormick's inquiry about hyperpyrexia (*JOURNAL*, March 20th, p. 554) to report a case of puerperal infection which he attended some years ago. The nurse who sent for him stated that the patient had a rigor and that the thermometer was "as high as it could go." On arrival Dr. O'Meara found that the thermometer registered about 113° F. He checked the reading with his own thermometer in the mouth and found it the same. The temperature fell to 105° during the day, but on the recurrence of the rigor at night it again rose to 113° F. The patient subsequently developed a pelvic abscess, which was opened in the left iliac region. She made a slow recovery, but afterwards bore several children.

LETTERS, NOTES, ETC.

RAW PANCREAS BY THE MOUTH IN THE TREATMENT OF DIABETES.

DR. R. CUNNINGHAM AFFLECK (Edinburgh) writes: Just over eighteen years ago uncooked pancreas was ordered by me to be procured and given to a patient, the widow of an army officer; but it was very necessary, I found, that particular care should be taken, so that what was ingested should actually be the pancreatic gland. If sweetbread was asked for no true sweetbread or pancreas was given by the seller, but the thymus and thyroid glands; these, by the sellers, are known respectively as "heart bread" and "throat bread." The thymus is also known as the "round bread"; to the seller the true pancreas is the "long bread" and also the "gut bread." The true pancreas, I discovered, was often thrown away; sometimes, if the man who slaughtered the animal took the trouble to remove it from the neighbouring intestines, the gland became his perquisite. In the form of bread sandwiches the lady found the "long bread"—that is, the true pancreas—quite pleasant and palatable. I am convinced that at present many experiences and results in dietetic experimentation err grievously, owing to the neglect of taking the precaution that my observation indicates; for example, a national food has been, as a result of recent experiment, condemned. In times past the effects of its consumption were excellent, but at present this particular food is almost invariably prepared differently from the old well tried way.

ANOTHER UNUSUAL PRESENTATION.

COLONEL P. BROOME GILES, C.B., F.R.C.S. (late A.M.S.), writes: Following Dr. W. B. Hunter on Dr. D. J. Malan in your issue of March 13th (p. 476), I well remember a similar case in my early career. A neighbouring practitioner sent a messenger on horseback urgently asking my father's assistance in a case of "locked twins." My father being out, I, who had only a few weeks previously finished being obstetrical assistant at University College Hospital, and keen, scenting a possible Caesarean section, with the usual confidence of youth, went to the case, which, on arrival, I was told was that of twins, the one presenting with the head and the other with a foot. The size of the abdomen, palpation, the stethoscope, and the normal size of the presenting foot negated turning and the necessity of a Caesarean section. After my senior had given chloroform to a full surgical degree,

I was able, with the loop of an ecraseur, to make sufficient traction on the presenting leg, and with combined internal pressure on the head and external pressure on the trunk to obtain a foot and breech presentation; as usual in feet presentation, there was a little difficulty in getting the arms down and rotating the trunk and head, but ultimately we produced a fine 8 lb. boy. To-day the mother is alive and the baby a grandfather.

EVOLUTIONAL MORALITY.

DR. G. D. PARKER (Flackwell Heath, Bucks) writes: The note in your issue of April 10th (p. 682), "Impregnatio mullieris artificiosa," is very interesting, and seems to me to open up a very important question of what one might term "evolutional morality." The law of evolution contains within itself the opposite law—that of degeneration, or reversion to type. It is possibly too little appreciated that this law is in operation coincidentally with the other; and it is a law probably easier of execution than that of evolution—"The descent to Avernus is easy." This artificial process seems to me a flagrant breach of the unwritten laws of eugenics. Why should an arrested individual, part of whose anatomy is in an early foetal condition, be helped and encouraged to propagate a probably degenerate and ill developed progeny? It would be profoundly interesting, but, I think, evolutionally profoundly immoral, to encourage a continuance of this special race of degenerates. Quite possibly, in another few thousands of years, we might get a sort of merman—mermaid race—fish-like people, even with external and patent gill clefts. It seems to me less aesthetically disgusting perhaps, but evolutionally as immoral as, the late German professor's (Peters's) attempt to mate black women with male gorillas. When it has taken us these millions of years to rise even into our present state of superficial civilization, why try to retrace our steps, not only till we become apes (or ape-like individuals) "with foreheads villainous low," but, later, fish-like creatures, and later still, possibly, pus cells, bacilli, fungi, and eventually fade, like the creations of Prospero in *The Tempest*, "into air, into thin air!" Look to it, eugenicists! What will Major Darwin, one of our greatest authorities, think of this?

BROMISM: THE SODIUM CHLORIDE TREATMENT.

DR. D. R. BLUNN (Leytonstone) writes: With reference to Dr. Semon's memorandum in the JOURNAL of February 27th, and the letter of Dr. Nichol in that of April 3rd, I have found the sodium chloride treatment of bromism very successful in two cases seen during the last month; in both the patients were not in the habit of taking salt with their food. In my experience a combination of calcium lactate and potassium citrate produces an even more rapid cure than the sodium chloride treatment. I give (thrice daily) calcium lactate gr. x, potassium citrate gr. xx, aq. ad 3j.

PELLAGRA IN NYASALAND.

SINCE the time when pellagra was first recorded as existing in Nyasaland (by Stannus in 1910) little has been done by way of investigating this disease on the spot, a disease which presents a number of interesting problems. Much might be done to solve them if those who have the opportunities of studying so widespread a condition would devote themselves to special points which still remain obscure. Dr. Shelley, medical officer of the hospital and prison at Zomba, has seen the advantages to be gained by observation of pellagrins who, in prison or hospital, are under control as regards regime and diet, and whose cases can therefore be investigated with thoroughness. A start has been made in a report, a copy of which has been sent to us, containing a brief account of certain points which have been impressed upon him. When a Director of Colonial Medical Services is definitely appointed he will be able to do a vast amount of good by issuing instructions as to the lines on which diseases such as this, found in almost every colony and occasionally in England, should be investigated, in order that the results may be properly correlated. Stray observations without strict controls, though entailing much work, produce little result and are therefore wasteful and uneconomical.

MEDICAL TOUR TO THE SPAS AND CLIMATIC HEALTH RESORTS OF ITALY.

DETAILS have reached us concerning the annual international visit of doctors to Italian health resorts, which, as already announced, will take place this year between September 12th and 25th. Among the places to be visited are Abbazia, the sea bathing resort near Fiume; Grado, also a popular seaside resort on the Northern Adriatic coast; the famous Lido (Venice); Abano, a spa close to Padua; Roncigno and Levice (arsenical waters), in the picturesque Trentino; Morano, the garden resort in the Dolomite region; Riva and Gardone, charming places for winter and summer on Lake Garda; and Salsomaggiore, the well known spa. Interpreters will accompany the party in order to assist at the conferences, discussions, etc., which take place during the tour. A limited number of places are reserved for wives and other relatives of the doctors participating. The fee for the whole tour from Abbazia to Salsomaggiore (fourteen days in all), including travel, hotel accommodation, meals at hotels and en route, tips, transport of baggage, etc., is only 1,600 lire—in all about £13. Moreover, tickets at reduced rates will be issued from any Italian frontier station to the starting point of the tour and from the point where the tour terminates to any Italian frontier station. The tour is accompanied by couriers, who take charge of the baggage, attend to all payments, and relieve travellers of all details incident to the tour. From experience of the previous occasion we have no hesitation in

recommending this tour to any readers who contemplate a trip of this kind. Further particulars may be had from the London office of the Italian State Railways and State Tourist Department, 12, Waterloo Place, Regent Street, S.W.1.

PREVENTION OF PUERPERAL SEPSIS.

AN Irish medical practitioner, in the course of a letter on this subject, writes to suggest that more attention should be paid to vaginal disinfection as a prophylactic measure. Cleansing of the lower part of the body is not easy in houses without baths, where the supply of boiled water is limited to a kettleful. He suggests, therefore, that a small cistern, in which a few gallons of water could be quickly boiled by a Primus stove, in country houses, would be most useful. Another boon would be packets of sterilized bed linen and bedgowns. He thinks it unfortunate that the practice of wearing rubber gloves is not yet general among maternity nurses, especially those of the older school and training. He asks also if there is no way of detecting, prior to labour, patients in whom there is liability to puerperal infection. He considers that vaginal douching after labour might well be combined with intrauterine douching as a preventive of sepsis.

SUPRAPUBIC LITHOTOMY.

DR. D. C. OZA (chief medical officer, Morvi State, India) reports two cases of suprapubic lithotomy—one in a man aged 55, the other in a child aged 5. The first patient required preliminary treatment for acute gonorrhoea; the bladder was found contracted and contained a flat stone the size of a small lemon. Before the operation an attempt was made to fill the bladder with boric solution, but not even half an ounce could be retained. The bladder wound healed completely on the eighteenth day of the operation, function was fully restored, and pre-existing incontinence ceased. Complete recovery also followed in the case of the child.

EPIDEMIC ENCEPHALITIS IN JAPAN.

R. KANEKO contributes an account of the epidemic of encephalitis in Japan during 1924 to the *Japan Medical World* of September 15th, 1925 (p. 237). The epidemic as a whole showed distinct differences from encephalitis lethargica, but many typical cases were encountered. Among these were a lethargic type closely resembling encephalitis lethargica; a myelitic type, in which bladder, motor, and sensory symptoms predominated; and an abortive type, with mild symptoms and no loss of consciousness. The length of the incubation period was not determined, but during the prodromal stage, headache, languor, dizziness, insomnia, and pain in the joints, chest, or hips, were present. A rise of temperature was the first sign of the onset. A characteristic disturbance of consciousness occurred sooner or later, varying in degree from lethargy to coma, and lasting from several hours to one or two days; there might be delirium and tremor, or convulsive movements of the hands. Various meningeal symptoms were seen, such as headache, backache, vomiting, stiffness and pain in the neck and extremities, and Kernig's sign. The cerebro-spinal fluid was turbid and under pressure, containing many leucocytes and a trace of globulin. The disease lasted usually one or two weeks; a few patients died within twenty-four hours, but in most cases death did not occur until after several days. In patients who survived the temperature fell in five to ten days, but recovery was very slow in the senile. The following three types of fever were seen: (1) A sudden rise of temperature, with or without prodromes; the general condition then became very grave and there was no remission or fall of the temperature. (2) A gradual rise for two or three days, the temperature remaining high for another two or three days, after which it gradually fell, the pyrexia extending over seven to ten days. (3) A similar rise as in (2), but the fall was sudden. This type was comparatively rare; it occurred in mild cases. Eye symptoms were seldom observed and complications and Parkinsonian sequelae were rare. This liver functions were very little affected, in contrast with lethargic encephalitis. The mortality was high, ranging from 38.7 to 55.6 per cent. in different places.

MOTOR CAR ACCESSORIES.

THE Lodge standard sparking plug, whose well known excellence is proof against its maker's designation as "Model C3," has recently been altered, so that, while still withstanding a considerable amount of oil or soot, it has even greater powers of resisting heat. As no soft packing is used inside the plug, it is possible to take it to pieces and the internal joint of steel. By oxidizing the body all risk of rusting is engine must now be as nearly perfect as it is possible to make it.

STEPNEY TYRES LTD. announce a reduction of 10 per cent. in their prices of Stepney motor car and motor cycle covers and tubes, both high pressure and balloon types. The reduction came into effect as from March 29th.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 43, 44, 45, and 48 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 46 and 47. A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 132.

A Post-Graduate Lecture

ON

CIRCULATORY CHANGES IN ANAESTHESIA
AND THE USE OF OXYGEN.*

BY

LEONARD HILL, M.B., F.R.S.,

DIRECTOR, DEPARTMENT OF APPLIED PHYSIOLOGY AND HYGIENE, NATIONAL
INSTITUTE FOR MEDICAL RESEARCH, HAMPSHIRE.

In considering the choice of a general anaesthetic we are guided by the fact that ether is far less liable to cause dangerous symptoms than chloroform and ought, therefore, to be always used in preference, excepting only cases where very special circumstances indicate the use of the latter. Chloroform is naturally preferred by those ignorant of its danger because it is less irritant, and, being potent in less concentration, excites less feeling of suffocation. Chloroform may have to be used in cases where excitement is to be avoided and very deep anaesthesia is to be obtained with complete muscular relaxation, in cases of bronchitis where the irritating effect of ether must be avoided, in the case of drunkards in whom ether sometimes fails to produce anaesthesia, and in cases where naked lights are necessary on the actual cautery used (that is, when the inflammability of ether forbids its use), and in very hot climates where, owing to rapid evaporation of ether and want of a proper closed apparatus for inhalation, it is difficult to produce anaesthesia. But in many of such cases the safe anaesthetic nitrous oxide and oxygen, if available, should be chosen, or the new anaesthetics recently introduced: 82 per cent. ethylene and 18 per cent. oxygen, which mixture seems safe apart from its inflammability 1 per cent. with 96 per cent. air forms an explosive mixture, or aethylene and oxygen, which, it is claimed, give fuller relaxation of the muscles and form a safe anaesthetic. Propylene is also said to be a safe anaesthetic. A mixture of 70 per cent. propylene, 25 per cent. oxygen, and 5 per cent. nitrogen induced analgesia in one minute, anaesthesia in two minutes, and respiratory failure only after sixteen to twenty minutes. The animals were easily revived after respiration had ceased for half a minute. Nitrous oxide and oxygen form an ideal anaesthetic, safe during, and leading to no bad effects following, anaesthesia, while in the case of chloroform, even after anaesthesia has been successfully conducted, necrosis of the liver follows in a not inconsiderable percentage of cases. We know that chloroform is a general cell poison; but as the cause of susceptibility of the liver in certain cases is unknown, no precautions can be taken against this accident other than shortening the period of anaesthesia, avoiding want of oxygen, and using a concentration no higher than necessary to secure anaesthesia. Such mixtures as A.C.E. are dangerous on account of the chloroform they contain, and their use should therefore be avoided just as much as that of chloroform. The conclusion reached by the American committee on anaesthesia was that the use of chloroform as the anaesthetic for major operations is no longer justifiable. For minor operations also the use of chloroform should cease. As a means of avoiding the ill effects of a prolonged period of ether excitement—in alcohol and other difficult subjects—the temporary employment of chloroform is, perhaps, sometimes the lesser of two evils. It is justifiable only when nitrous oxide is not available. If a change to chloroform has to be made, it should be made early, as soon as the difficulty of anaesthetizing with ether becomes evident. I wish to emphasize the point that chloroform should never, in any circumstances, be administered after a prolonged period of fifteen minutes or more of ether excitement. Even a small administration of chloroform is then peculiarly liable to induce respiratory or cardiac death. As

soon as full anaesthesia is obtained ether should be substituted.

"Physiological experiment," said Waller, "shows that ether is five or six times safer than chloroform—that is to say, it takes a concentration of ether five or six times greater to produce poisoning of living tissues." The margin of safety in administration of ether is obviously, then, very much greater. Cushing says that no less than thirty-six times more ether than chloroform must be added to the blood in order to bring the frog's heart into a condition of diastolic standstill.

"The moderately healthy patient under ether," says Hewlett, "may be raised into the sitting posture; he may be subjected to an operation before he is very deeply anaesthetized. His air supply may be so restricted that a considerable degree of cyanosis is occasioned; and yet his circulation will not show that liability to comparatively sudden fluctuations and depressions which undoubtedly occur under chloroform." In addition, under ether "respiration usually is so obvious and audible that any alteration in the function of breathing may at once be detected"; the sleep-like and inaudible respiration not infrequently met with under chloroform is almost unknown under ether. Under ether the pulse is full, bounding, and regular, the blood pressure about normal, the face is abnormally flushed, and incised parts, more especially in the neighbourhood of the neck, are very vascular. "With an overdose of ether, the circulation at the moment when breathing ceases is sufficiently satisfactory for remedial measures to be almost invariably successful, early syncope as under chloroform does not occur." It is only in bad subjects with dilated, fatty, or diseased hearts that syncope may occur under the asphyxial strain of inducing ether anaesthesia. But under chloroform the healthiest subjects may die from heart failure.

Ether anaesthesia should be induced quickly and kept as uniform as possible to prevent excessive breathing and consequent washing out of carbon dioxide from the body, which may result in a period of apnoea, the concentration of carbon dioxide in the blood being the natural stimulant of the respiratory centre in the brain. During apnoea want of oxygen ensues until the centre becomes excited by this; but to produce such want of oxygen is unwise. The poisoned centre may fail to be excited.

Want of oxygen by itself, if sufficient, results in anaesthesia. Consciousness is suddenly lost on breathing nitrogen for some fifty seconds, and speedy minor operations, such as extraction of teeth, have been done under such anaesthesia. But we know that prolonged want of oxygen, as in those rendered insensible by breathing carbon monoxide, leads to degeneration of tissues, such as the heart and brain, from which recovery is difficult or impossible.

Want of oxygen has an injurious effect on living cells such as chloroform or ether has, and adds its ill effect to theirs. Diabetics suffer especially from want of oxygen, some degree of which always accompanies the use of these anaesthetics. For them such an anaesthetic as nitrous oxide and oxygen is most necessary. But for all cases want of oxygen should be avoided as much as possible.

Ether and oxygen has been used, but this mixture is highly inflammable. A mixture of such has recently exploded in a patient's throat, probably through overheating of a syringe which was used to dry the teeth in a dental operation.* The trouble about using nitrous oxide and oxygen for a prolonged general operation is that it is impossible to get complete muscular relaxation without bringing into play some want of oxygen by lowering the concentration of oxygen and raising that of nitrous oxide in the inhaled air. A mixture of 40 per cent. air and 60 per cent. nitrous oxide would contain about 8 per cent. oxygen and about 32 per cent. nitrogen, and although the oxygen would just suffice to keep the patient going the 60 per cent. of nitrous oxide would be insufficient to produce tranquil, deep anaesthesia. By using oxygen in place of air we replace nitrogen by nitrous oxide, and the proportion of the latter can be raised to 90 per cent. and better anaesthesia obtained.

* A temperature of 209° C. suffices to effect the explosion.

Being the third of three lectures on general anaesthesia delivered for the auspices of the Dental Board of the United Kingdom in 1925. The two other lectures, which were by Professor Vandell Henderson, were published in the BRITISH MEDICAL JOURNAL on December 19th, 1925 (1170), and January 9th, 1926 (p. 41).

Nitrous Oxide.

By raising the concentration of nitrous oxide still further deep anaesthesia with full relaxation of the muscles is obtainable. Paul Bert effected this by using a pressure chamber as an operating theatre, in which patient, surgeon, anaesthetist, etc., were all contained. A short length of tube railway would do for such a chamber, closed at one end completely, and provided with a suitable air lock for passing in and out at the other end, and an air pump for raising the pressure and maintaining ventilation. The required increase of pressure is very small—for example, half of an atmosphere. In place of, say, 90 per cent. of an atmosphere of nitrous oxide and 10 per cent. of an atmosphere of oxygen, we should then have $90 \times 1.5 = 135$ per cent. of an atmosphere of nitrous oxide and $10 \times 1.5 = 15$ per cent. of an atmosphere of oxygen, which will give deep anaesthesia and enough oxygen. The circulation and respiration are in no way influenced by this anaesthesia, which may be maintained for several hours. If an animal is kept warm it will, as Dr. H. H. Dale and I have found, confirming Bert, at the termination of anaesthesia be in splendid condition without any sign of shock, and able at once to run across the room fully alert. Such a method of anaesthesia is safe even in the hands of students; there is no difficulty in constructing and using such an operating theatre if the demand for it were made. Through the air lock people could pass quickly in and out, and inside everything would be conducted just as in an ordinary operating theatre, the gas and oxygen mixture being administered in the ordinary way, all inside being submitted to a slightly increased atmospheric pressure. The only precaution to take would be opening of the Eustachian tubes by a deep expiration with mouth and nose shut, so as to equalize the pressure within and without the middle ear. People with tubes swollen by catarrh might be troubled in effecting this. Tunnel workers carry out work in pressures up to two, three, and even four atmospheres in the caissons which are used to keep water out when boring under rivers; half an atmosphere extra pressure is, then, of very little account.

Nitrous oxide and oxygen offer an ideal anaesthetic for dental surgery; the average time of inhalation Hewlett found to be 110½ seconds, the average available time 44 seconds, but varying from 21 to 90 seconds. The addition of a small dose of ethyl chlorido is effectual in prolonging the anaesthesia, and appears to be a safe proceeding.

When pure nitrous oxide is administered with the ordinary valved apparatus there results anaesthesia, partly from this gas and partly from deprivation of oxygen. To-and-fro breathing during the last part of the inhalation allows some small amount of oxygen to be retained, and a longer inhalation and period of anaesthesia to be obtained. The exhaled carbon dioxide which is thus re-breathed deepens the breathing. There is, however, a disadvantage in breathing into the bag, because it is difficult to clean and disinfect it for another patient. By using an apparatus such as the Salvus used in mine rescue work, with a caustic soda absorber placed between the mouth mask and the bag, this trouble might be obviated. Each patient would have his caustic soda cartridge to breathe

through. A suitable modification would have to be made to secure sufficiency of oxygen for prolonged anaesthesia.

The circulation is well maintained during nitrous oxide anaesthesia, providing too great a degree of asphyxiation is prevented; the pulse increases in frequency and loses in fullness; flabby, stout patients become deeply cyanosed; the moment air is breathed the pulse becomes less frequent and fuller; the muscular spasms which occur are due to want of oxygen. To obtain the best results, then, it is necessary to eliminate asphyxial symptoms, and mix oxygen with nitrous oxide. All the deaths which occur from use of this gas appear to be due to fright or to want of oxygen, and not to the poisonous nature of the gas. If the air leaks into a mask during inhalation of nitrous oxide, the oxygen in this air is quickly absorbed by the patient, and the nitrogen, which forms four-fifths of the air, remains and dilutes the nitrous oxide; thus want of oxygen increases, and anaesthesia results more from this than from nitrous oxide. It is necessary to have a close-fitting mask to avoid such leaks.

FIG. 1.

FIG. 2.

FIGS. 1 AND 2.—Record of blood pressure in aorta and vena cava of a dog anaesthetized with ether, and placed in the vertical position (head up) with the cannulae inserted in the vessels in the axis of rotation. The vena cava pressure falls and the respiratory waves are heightened; the aortic pressure at first falls and then rises, and compensates the effect of gravity for a time; finally it slowly falls, with variations produced by increased depth of respiration as shown by the vena cava record.

FIG. 3.—Record of aortic blood pressure of a dog under morphine. A, The animal was placed in the vertical posture (head up) and the preliminary fall in blood pressure was largely compensated until B, chloroform was breathed in concentrated doses. The blood pressure then fell sharply. After stopping the administration of chloroform at C, the abdomen was compressed between D and E and the blood pressure thereby largely restored. Placing the animal in the head-down position at F had the same effect.

action, and under certain conditions fibrillar contraction, the cause of sudden syncope and death. Added to oxygenated blood it dilates the blood vessels of surviving organs, but constricts these if the blood lacks oxygen or is replaced by Ringer's solution. It relaxes the skeletal muscles which support the veins, thus enlarging the capacity of these great veins into which the whole of the blood can easily drain from the upper part of the body when the body is put in the upright position. The cross circulatory experiments of Gaskell and Shore showed that chloroform does not affect the vasomotor centre so as to lower the arterial pressure in the early stages. It may even excite this and raise the arterial pressure at first. In very deep anaesthesia the vasomotor centre is depressed in action just as the respiratory centre is, and arterial

dilatation may take place. With ether also, after an hour or so of anaesthesia, progressive dilatation sets in. The respiratory pump helps the circulation greatly, furthering the return of blood by rhythmic compression of the abdomen and rhythmic enlargement of the lungs, in which enlargement the pulmonary vessels share. When the respiration pump is enfeebled by deep chloroform anaesthesia everything tells against the circulation—the dilated, feeble heart, the relaxation of the abdominal veins, and the feeble action of the respiratory pump. Hence there is danger in the upright position of the blood draining into the abdominal veins, the heart almost emptying, and the circulation in the brain almost ceasing. Such conditions help to stop the respiration, the respiratory centre itself being partly poisoned by chloroform and much less responsive to the natural stimuli of breathing.

The capillaries—there are, according to Krogh, some 2,700 in each square millimetre of diaphragm muscle—are supported by the contractile cells of Rouget and by the tissues in which they run. They may become dilated by chloroform, and the blood pool within them as well as in the

Chloroform.

Chloroform is a poison to living cells, acting perhaps on the fatty surface film which controls permeability and adsorption. On the heart it causes dilatation and weak

big veins. In favour of this is an observation of Argyll Campbell that chloroform anaesthesia lowers the tension of oxygen in the tissues, while ether may slightly raise it. Many capillaries in resting organs such as muscle are normally closed. In states of shock the capillaries are dilated, probably by absorption of histamine into the blood from damaged tissues; chloroform and ether increase this effect. Fluid also passes out then from the capillaries into the tissue spaces. The whole body confined by the skin is kept taut and hard, or should be, by the inhibition pressure of the living cells of the tissues. Each organ has its capsule of connective tissue limiting its expansion, in addition to the skin which confines the whole, the brain, spinal cord, and marrow being confined by bone; expansion is thus limited. The tissue cells thus confined, when healthy and in good tone, are swollen with fluid so as to produce a certain tissue pressure, and the capillary pressure is adjusted so as just to balance this and exceed it just to the amount sufficient to cause the flow of blood into the veins, an amount which need be, and is, very small. The conduction of the arterial pulse wave and its driving force depends largely on the tone of the tissues which support the arteries. In shock the tone of the body is generally relaxed, and the blood stagnates in dilated veins and capillaries and sinks to the lower parts of the body. Histamine, a product of tissue damage, dilates the capillaries, and is probably closely associated with the causation of shock. To both pituitrin and adrenaline has been ascribed the function of supporting capillary tone.

Chloroform, by poisoning the tissue cells and relaxing their tone, makes the whole body flabby, turns the circulation from a vigorous one through confined channels in a taut body to a sluggish one in a relaxed body, and the blood in consequence stagnates in dependent parts—hypostatic congestion. The failure of the circulation in deep anaesthesia can be got over by supporting the vascular system, by putting the body horizontal or with the legs and abdomen slightly the higher, or by compressing the abdomen, while failure of respiration can be met by artificial respiration.

Far more dangerous, and the main cause of deaths under chloroform, is cardiac fibrillation, which occurs in the initial stages of anaesthesia, and may be a consequence of too light an anaesthesia and of struggling or sensory excitation. The distinguished medical statistician M. Greenwood has concluded that the condition called status lymphaticus, often made an excuse for fatalities arising from anaesthesia, is a make-believe.

MacWilliam first pointed out that dilatation of the heart occurred, and that this was due to the action of chloroform on the heart itself, and that fall of blood pressure was concomitant with this. In some cases he found the heart thrown into a state of inco-ordinate fibrillar contractions. These waves are quite ineffectual in maintaining a circulation. These facts I confirmed. Goodman Levy has shown that the reapplication of chloroform in concentration of about 2 per cent. or over after an interval may act as a powerful excitant to the upper air passages, and the sensory excitation therefrom may throw a heart, already made irregular by chloroform, into fibrillation. In deeply morphinized dogs inhibition of the heart, reflexly

excited by breathing strong chloroform, may help to embarrass the heart. Prolonged intense stimulation of afferent nerves which reflexly arrest the respiration and inhibit the heart may cause in animals a failure of respiration, to be followed by that of the heart if unrelieved by artificial respiration.

Want of oxygen is another cause exciting the whole sympathetic system, including the accelerator nerves, and causing, probably, increased adrenal secretion, which helps to produce the fibrillation, this being a most powerful cardiac stimulant. An injection of adrenaline may throw the weakly chloroformed heart into fibrillation; but according to MacWilliam, while a small dose has this effect, augmenting excitability, a large dose has the opposite effect, and may be used to stop fibrillation. Direct excitation of the accelerator nerves may provoke fibrillation; painful stimuli in the half-anaesthetized patient reflexly excite these nerves. A cardiac depressant, such as chloroform in full dose, prevents these irritable phenomena—hence the danger of light or irregular administration and safety of deep, full anaesthesia. The latter damps down or cuts out the reflex exciting mechanism, and so protects the heart from any sensory excitation acting reflexly on the accelerator

nerves. Fibrillation is due to a disturbed relation between the conduction time of the stimulus and the refractory period, resulting in the setting up of circulatory excitations in the musculature of the heart. The heart tends to recover spontaneously from fibrillation, but spontaneous recovery in animals does not occur after the first minute or minute and a half. Such spontaneous recovery has even been observed in man by means of an electro-cardiographic record.

Bathing the chick embryo in a suitable nutritive solution to which chloroform is added shows the poisoning action on the heart. So, too, does perfusion of the isolated mammalian heart through

FIG. 4.—Respirations and blood pressure records showing the reaction to adrenaline in a cat under chloroform. *a*, Respiration. *b*, Blood pressure (mercury manometer). *c*, Level of zero pressure. *d*, Signal line. *e*, Time, indicated in seconds. *A*, intravenous injection of half a minim of 1 in 1,000 adrenaline solution when the cat is under 1.5 per cent. chloroform. The blood pressure rises, but the beat remains regular. *B*, A similar injection when the cat is under 0.2 per cent. chloroform. The beat becomes rapid and irregular, and finally ceases abruptly. Following the cardiac collapse the respirations are first greatly

exaggerated and then cease entirely. (Levy.) the coronary vessels with blood to which chloroform is added; Sherrington and Sowton found that the heart is weakened progressively as the strength of the chloroform in the perfusion fluid is raised: finally the heart stops beating and does not recover. The strengths of chloroform used for inhalation, however, do not produce this stoppage, because the respiration fails first when too concentrated a dose occurs, and then the heart can be recovered by artificial respiration. The fatal cases of syncope are due to fibrillation, and these can be recovered, according to MacWilliam, by injecting 0.1 to 1 mg. of adrenaline (using a 1 in 10,000 solution) into the cavity of the left ventricle, or by rhythmic massage of the heart. To effect this massage through the chest wall is very difficult in an adult man. The method then to follow is to make an abdominal incision and through this cut the attachment of the diaphragm to the left costal margin for two inches. The left hand is inserted into the left pleural cavity and the heart grasped through the pericardium and rhythmically squeezed, the wrist preventing air entering the pleural cavity. The rate of compression should be about that of the normal heart. Massage should not be abandoned under an hour, short pauses being allowed at intervals. An occasional intermittent compression of the abdomen to fill the heart helps. Perflation of the lungs by mouth-to-mouth method, or by a stream of air or oxygen blown in by

intubation of the larynx, must be kept up. Artificial respiration can be first tried, but in this desperate condition there must not be more than a very few minutes' delay before direct massage of the heart is begun, because if delay is too long, even though the heart recovers, the nervous system is damaged by prolonged oxygen starvation, and the patient dies from this reason. When the heart gradually fails from overdosage, artificial respiration, conducted by squeezing the chest rhythmically, will recover it by bringing fresh blood into the coronary arteries and through the lungs, and so getting rid of the chloroform and admitting a supply of oxygen. MacWilliam finds that injection of 0.5 gram per kilogram of body weight of urethane beforehand prevents fibrillation in animals during chloroform anaesthesia.

Ether.

When ether is the anaesthetic, the symptoms of poisoning are in general the same, but fibrillation or failure of the heart from overdosage is much more unlikely because of the far lower toxicity of the drug. The anaesthetic partial pressure of ether is 3.7 to 4 per cent. of an atmosphere. The solubility of the brain tissue for ether is practically the same as that of blood. Large pulmonary ventilation and rapid blood flow through the brain results in quick anaesthesia.

In every operating theatre there should be available a cylinder containing oxygen and 5 per cent. carbon dioxide. By using this with ether at the beginning of anaesthetization deep breathing is obtained and quicker narcosis. A lower percentage of ether can be used and less irritation of the bronchial mucosa caused. After prolonged ether anaesthesia the colour and fullness of the veins in the skin are restored by breathing this mixture (Yandell Henderson and Haggard). By using it alone after operation the deep breathing excited by the carbon dioxide washes ether out of the body and introduces oxygen; this greatly lessens the after-effects and helps recovery. It is an advantage to give a liberal dose of morphine half an hour before initiating anaesthesia. This takes away anxiety, lessens the period of excitement, decreases pain after anaesthesia, and is an excellent preventive of shock. The breathing of the oxygen CO₂ mixture

after operation counterbalances the depressive action of morphine on the respiratory centre.

In animals chloralose or urethane (6 c.cm. of a 25 per cent. solution per kg. body weight) injected subcutaneously, or into the rectum, gives narcosis with a high blood pressure, and is very convenient.

Ether in oil introduced into the rectum, after washing this out, produces anaesthesia which may be long lasting. This plan has been suggested for use when no help is at hand to give this anaesthetic by inhalation.

Local Anaesthesia.

Turning to local anaesthesia, we know that cocaine is a general protoplasmic poison, and its poisoning action is exerted on the central nervous system, the symptoms being excitement, convulsions passing into coma, and death from asphyxia. The blood vessels are contracted, blood pressure raised considerably, the heart also being accelerated in the stage of excitement. A local contraction of the vessels is caused by the application of cocaine. The artificial alkaloids used as a substitute for cocaine are much less poisonous, and have not the same constricting effect on the blood vessels. Thus novocain is quickly destroyed in the liver, and is for this reason much safer. Adrenaline increases the toxicity of cocaine according to the findings of the committee of the American Medical Association. This committee believes that local anaesthetics may be applied safely in the following concentrations and total amounts: Cocaine in the mouth 5 per cent., in the nose up to 10 per cent., and in total amounts of from 10 to 15 minims containing at most 1 to 1.5 grain. In the eye not over 5 per cent. should be used. In the larynx 10 per cent. and not over 15 minims, containing 1 to 1.5 grain. Novocain in concentrations not greater than 1 per cent. Adrenaline or epinephrine should not be used with cocaine in concentrations greater than 1 in 10,000, and not more than 10 minims of this—with novocain up to 1 mg. of adrenaline—is allowed; but even this dose may be unsafe in patients suffering with hyperthyroidism (exophthalmic goitre). In poisoning cases the heart must be massaged by artificial respiration to keep up the circulation through the liver; the injection of any other drugs is probably useless, and may increase the danger.

FIG. 5.—Ventricular fibrillation initiated during a fit of struggling in a cat under light chloroform anaesthesia. Upper record: respiratory. Lower record: blood pressure (mercury manometer). Time marked in seconds. The period of struggling is indicated by the irregular respiration record within the dotted bracket. The cardiac collapse is followed by intense dyspnoeic gasps. The heart was in fibrilla left of the graph.

dose may be unsafe in patients suffering with hyperthyroidism (exophthalmic goitre). In poisoning cases the heart must be massaged by artificial respiration to keep up the circulation through the liver; the injection of any other drugs is probably useless, and may increase the danger.

RECOVERY AFTER MASSAGE OF THE HEART.

BY

W. GIRLING BALL, F.R.C.S.Eng.,

SURGEON WITH CHARGE OF OUT-PATIENTS, ST. BARTHOLOMEW'S HOSPITAL.

The following case is one of considerable interest, as it illustrates the value of massage of the heart when it has ceased to beat during the performance of a major surgical operation.

History.

A man, aged 50, was admitted under my care to St. Bartholomew's Hospital on September 28th, 1925. His story was as follows: In October, 1913, he was admitted to the hospital with perforation of a gastric ulcer, which was sutured by myself; a posterior gastro-enterostomy was performed at the same time. He made an uninterrupted recovery, and departed for West Africa, where he has been living up to this time. In 1916 he had a bad attack of dysentery. In 1918 he began to have a grinding pain in the neighbourhood of the umbilicus on the left side of the abdomen, extending towards the left iliac fossa; the pain usually came on about three hours after food and lasted for an

hour or two. From time to time this pain would disappear for a period of two or three months; since 1920, however, it had gradually become more persistent, and as a result thereof his life had become very miserable.

On admission to hospital he looked fairly well, but his facies suggested that of a man suffering from constant pain. His teeth had all been removed, so that oral sepsis was excluded as a cause of his symptoms. There was well marked tenderness to the left of the middle line in the epigastric region; over this point of tenderness there was an area of superficial hyperaesthesia. His pain was only partially relieved by placing him on a convalescent diet. The character of the pain suggested that he might have a gastro-jejunal ulcer, and I decided to explore his abdomen to settle this point.

Operation.

On October 2nd he was anaesthetized by the endotracheal gas-oxygen-ether method. No ulcer or scar could be found in the region of the site of the old perforation, but there was thickening around the gastro-jejunal junction on the proximal side of the stoma, which was involving the transverse colon and was obviously the site of a gastro-jejunal ulcer. The jejunum was divided proximally and distally to the stoma and an end-to-end anastomosis made. The transverse mesocolon was then separated from the anastomosis and its adhesion to the colon divided. The ulcer had not actually perforated into the colon; the point of

attachment, however, was very thin, and as a precaution was sewn over; the hole in the transverso-mesocolon was closed. The omentum and the gastro-hepatic omentum were then separated from their attachments to the stomach.

Massage of the Heart.

At this stage the patient suddenly stopped breathing and his heart ceased to beat. His head was lowered and oxygen only was passed down the intratracheal tube under intermittent pressure. The stomach was rapidly separated, between clamps, from the duodenum and thrown over to the left side of the abdomen. The heart was then gently massaged through the diaphragm at the rate of about sixty to the minute, artificial respiration being kept up meanwhile; 10 minims of 1 in 1,000 adrenaline were injected into the heart muscle through the chest wall. Three minutes elapsed before any sign of heart movements was noticed, when a single forcible contraction was felt; this was followed by fibrillary twitchings for about ten seconds, and was then succeeded by a series of regular, rapid, feeble beats until gradually it beat with its normal rhythm, but at rather a rapid rate. Shortly after the heart began to beat the patient commenced to breathe. Hot packs were placed on the chest wall and the operation was proceeded with, a Billroth No. 1 anastomosis being made, after having excised the distal half of the stomach with the gastro-jejunal anastomosis. This operation took forty minutes to complete, the anaesthesia being continued with pure nitrous oxide-oxygen through the tracheal catheter.

In the excised portion of stomach there was no sign of the old gastric ulcer, but there was a small gastro-jejunal ulcer, a third of an inch in diameter, surrounded by an indurated wall, on the left side of the junction.

After-History.

The patient was returned to bed with hot-water bottles and was given rectal injections of saline and glucose. His pulse rate remained very rapid and its volume was very small, but at the end of three hours he showed signs of recovery and became extremely restless. His temperature remained normal, but the respiratory and pulse rates were raised for about ten days. Some suppurative took place in the abdominal wall.

Ten days after the operation he had a severe haematemesis, which was followed by another two days later. He was put on a modified Lenhart diet. From this time onwards he began to improve and made an uninterrupted recovery. When discharged from the hospital, on November 21st, he was taking a light diet, was free from symptoms, and was putting on weight. He has remained well, without any further symptoms. The wound was healed and the pulse, temperature, and respiratory rates were normal. A barium meal, given just prior to his departure from the hospital, demonstrated that the new channel was working satisfactorily. He saw me on March 17th, 1926, stating that he had no symptoms, was quite fit, and was leaving for Uganda.

There are some points worthy of comment in this case, apart from the recovery of the patient. Up to the moment of his collapse there was no indication that this was about to happen; in fact, only just prior to the moment I had commented to the anaesthetist that he was standing the operation well. In the second place, it is surprising that, in addition to obtaining a recovery of the heart's action, it was possible for me to complete the operation, which took at least another forty minutes. Naturally, the completion of the operation was carried out under a severe stress, and it is my belief that the haematemeses were of the nature of secondary haemorrhages, probably due to faulty technique.

Cases of recovery after massage of the heart are, of course, on record, although in many instances failure occurs; the patients survive the operation, but either never regain consciousness or die of some lung complication. In some cases the abdomen has required to be opened in order to perform necessary manipulations. In this case, however, although some preliminary manœuvres had to be effected, owing to the nature of the operation in hand, in order to reach the diaphragm, very little time was lost before massage was commenced. In addition, it is possible that recovery was naturally aided by the presence of a tracheal catheter in position at the moment of cardiac failure, which permitted the immediate inflation of the lungs with oxygen under pressure; so that while the heart was being massaged the artificial circulation provided sufficient oxygenated blood to the brain to obviate the cerebral anaemia which usually proves fatal in these cases. The production of a pink coloration of the patient's face with each artificial pulsation of the heart was a very noticeable feature. The diaphragm was not incised, but the heart was squeezed by the right hand inserted under the diaphragm while the heart was pressed against the anterior chest wall. So far as could be observed, both before and after the operation there was no heart lesion.

I am indebted to my house-surgeon, Mr. Dodd, and to the anaesthetist, Mr. Hewer, for so ably assisting me to bring about the man's recovery.

Lumleian Lectures ON ENDOCARDITIS.

BY
SIR THOMAS HORDER, Bt., K.C.V.O., M.D.,
PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

LECTURE III.*

I PROPOSE now to deal with the anatomical and bacteriological parts of my subject, and then with considerations of diagnosis, pathogenesis, and treatment.

STATE OF THE ENDOCARDIUM BEFORE INFECTION.

The state of the valves prior to the onset of septic endocarditis is an important point. In my original series of 118 *post-mortem* examinations in 150 cases I found evidence of old valve disease in 80 per cent. The figures of other observers approximate very near to this. But it is to be noted that this figure refers to acute and chronic cases when taken together. If we consider acute cases alone the figure is undoubtedly much smaller. If we take the series of cases of ex-soldiers by themselves we find it smaller still. Thus, out of 13 autopsies in this class Starling found scarring from old rheumatic disease in one only. Carey Coombs's experience is much the same. The inclusion of 20 cases of ex-service men explains why, in a second series of 162 cases at St. Bartholomew's Hospital, the figure is only 50 per cent. You, Sir, in the course of the Lumleian Lectures given by you in 1920, stated that, despite the prevalence of sepsis in the wounded during the great war, infective endocarditis was uncommon; that a number of acute and rapidly fatal cases of the disease occurred in men in whom no primary source of infection could be found *post mortem*; and that in these cases the infection had attacked healthy valves. Summing up, therefore, it may be said that in acute cases generally, and in the chronic ex-service cases, there is a notable absence of pre-existing valvular disease; in chronic civilian cases there is a marked preponderance of pre-existing valvular disease. It has perhaps been too readily assumed that the nature of the pre-existing valve damage found at autopsy is generally rheumatic in origin. Care must be taken, as Libman has pointed out, to distinguish the residues of rheumatic infection from the residues of an old septic endocarditis, since it is now known that this latter process may recur after years of apparent freedom from active infection. The patient's history is therefore of great importance in judging the nature of cicatricial and of sclerotic changes in the valves. Since pericarditis is known to be quite rare in chronic septic endocarditis, evidence of this at autopsy is much in favour of old rheumatic infection. The type of myocardial disease, if this be present, may also assist in a correct interpretation of the findings.

Of the valves affected it is again important to distinguish acute from chronic cases, and civilian chronic cases from ex-service chronic cases. In acute cases the incidence of mitral and aortic disease is probably about equal. Of 34 such cases due to *Streptococcus pyogenes* Thayer found the aortic valve involved in 20 cases, the mitral in 26. Gonococcal infection, however, tends to attack the aortic valve by precedence. Thayer's cases, forming the fullest series of which we have details, showed 66 per cent. aortic and only 19 per cent. mitral. There were right heart lesions as often as mitral in this infection. Of 40 cases of pneumococcal endocarditis, Thayer found the aortic cusps involved in 20, the mitral in 13, and the valves on the right side of the heart in 7 only, thus disposing of the fallacy that pneumococcal infection is prone to attack the right heart chiefly. In chronic septic endocarditis, however, there is a preponderance of mitral infections in civilian cases, and a still greater preponderance of aortic cases in ex-soldiers.

MURAL INFECTION.

Mural infection is, I believe, more common than is generally thought. I found instances of this condition in 52 per cent. of 118 *post-mortem* examinations. Thayer's figure is as high as 84 per cent. in chronic cases. Auricular

* Delivered before the Royal College of Physicians, London, on March 30th.

infection is much more common than ventricular. The occurrence of mural endocarditis is usually attributed to the influence of pre-existing scars from old rheumatic disease. The occurrence of mural lesions without valve lesions must be quite rare. I cannot find any case in the literature which is at all comparable with one which I described in my original series, and where, fortunately, a *post-mortem* examination was possible. The disease had lasted for over two years, the type being very chronic, the fever very mild. There was no sign of valvular disease during life. This patient was for some weeks in a sanatorium on account of pyrexia, sweats, and malaise, it being thought that she might be a case of pulmonary tuberculosis without physical signs. She developed multiple infarction of the spleen, and blood cultures were positive. Eventually she died of cerebral embolism. *Post mortem* there was found a small area of fungating auricular mural endocarditis, situated well above the mitral orifice, the cusps of which were natural. The importance of knowing that such cases exist lies in the fact that the disease may be present in the absence of signs of valvular mischief. But, as already stated, such cases are rare.

PARASITOLOGY.

I pass now to a consideration of the parasitology of endocarditis. I need not dwell upon the infecting agent in the syphilitic cases, except to point out that all the evidence favours the view that the route of infection is by the vasa vasorum to the middle coat of the aorta, and that it is therefore probable that the aortic cusps are infected likewise from the depths rather than from the surface.

Nor must I dwell long upon the old controversy as to the causative agent in acute rheumatism. Of late years there has been a growing tendency to consider the streptococcal origin of acute rheumatism as proved. But clearly this is not so, and it seems to me that we do but obstruct further research by so premature a conclusion. With due deference to Poynton and Paine, whose thorough and masterly work all must admire, it is to be doubted if the real picture of acute rheumatism has yet been experimentally produced in animals by the use of the *Diplococcus rheumaticus*. Nor is there so far anything like unanimity amongst the many observers who have given pains to the question of blood cultures in rheumatic fever and to the bacteriological investigation of fatal cases of the disease. Unfortunately the opportunities for this particular research become less and less with the decrease in incidence of severe rheumatic fever, but when the disease was rife, and even now, when it occurs, the number of negative results in the hands of skilled bacteriologists were, and are, strikingly large; and this, too, when the most approved culture methods are adopted. Such strains of cocci as are occasionally found in these cases seem to possess no special features, and considerable weight must be attached to the fact that the blood in cases of acute rheumatism has failed to yield any specific serological affinity, even for those homologous streptococci that have been isolated from the circulation of rheumatic patients. Such is the experience of Swift and Kinsella, who record the following striking case. A streptococcus was isolated from the blood of a patient in a first attack of rheumatic fever. A relapse occurred after a year of good health, and a second streptococcus was this time isolated. The two streptococci differed culturally and serologically. No complement-fixing antibodies against the first streptococcus could be demonstrated in the blood at the time of the second infection. Clawson and Bell have quite recently claimed to obtain a streptococcus by blood culture in 50 per cent. of cases of rheumatic fever. Yet they, again, failed to find antibodies in the blood at a serum dilution higher than 1 in 50. On the other hand, Clawson considers that he has produced lesions in rabbits' hearts which were morphologically identical with the Aschoff nodule, by the use of rheumatic strains of streptococci. He therefore concludes that streptococci, generally of the *viridans* type, are responsible for rheumatic heart lesions in man. This vexed question must still be considered as undecided.

In acute cases of septic endocarditis the nature of the infection calls for no special comment. Positive blood cultures are forthcoming in nearly all cases, and, as already

remarked, the micro-organisms are of a highly virulent type. Until the role of the streptococcus in acute rheumatism is more clearly defined—whether, for example, it is the primary cause or only present in the disease as a secondary infection—we cannot profitably discuss the question if some of the cases of chronic septic endocarditis may not be justly regarded as cases of "malignant rheumatism." Such a conception is only rendered probable by assuming, with Poynton, that the rheumococcus remains latent in the endocardium for, it may be, many years. This seems less probable than that the disease is the result of a new infection grafted upon the old damaged valve, and this view is the one most generally accepted at present.

Positive blood cultures in the chronic cases are, as already mentioned, by no means invariable. In my early series of mixed acute and chronic cases I found micro-organisms in the blood in nearly 90 per cent. of cases at some stage of the disease. Libman gives the same figure for his cases. But in a second recent series of 162 cases at St. Bartholomew's Hospital the number of positive blood cultures was only 47 per cent. This was largely due to the inclusion in the series of a much larger proportion of chronic cases, and especially of twenty ex-service cases; in these twenty cases the number of positive blood cultures was only 30 per cent. This paucity of positive cultures in the ex-service class corresponds with the experience of other observers. The micro-organisms found in these cultures are almost entirely streptococci; the exception is the strange one of Pfeiffer's bacillus, which crops up with extraordinary constancy in the series of all observers, provided the number of cases in any series be not too small.

There seems little reason to doubt that the cocci recovered from the circulation during life, and also those isolated from the diseased endocardium after death, by various observers, have been of the same type, though called by different names. The difference in names has depended upon the different principles adopted in the segregation of the streptococcus and pneumococcus groups. My original description of these cocci was based upon Gordon's well known work, in which the morphological and cultural characters of these micro-organisms were supplemented by biochemical reactions in various sugars. Working in conjunction with Andrews we were able to trace very close affinities between the streptococci associated with chronic septic endocarditis and the salivary and faecal types as differentiated by Gordon. Schottmüller's nomenclature was based largely upon the fact that these streptococci reacted in a special manner on blood-agar plates; hence his term "*Streptococcus viridans*." Rosenow, on grounds which need not be entered upon here, claimed to have obtained evidence that these comparatively non-virulent cocci are modified pneumococci, and that by frequent passage through animals, and by special anaerobic cultural methods, they could be converted into micro-organisms indistinguishable from pneumococci and possessed of considerable pathogenicity. I am unaware that this work of Rosenow has been confirmed. Libman is content to term the coccus most commonly found in chronic septic endocarditis, "*Streptococcus endocarditidis*." But when we consider questions of pathogenesis it is obvious that the nature and origin of these streptococci become matters of great importance. Too much attention cannot, therefore, be paid by bacteriologists to the life-history of these cocci and to their probable source.

THE BACTERIA-FREE STAGE.

This is perhaps a convenient place in which to refer to Libman's views upon what he terms the "bacteria-free stage" of chronic septic endocarditis. I have already confessed to my inability to accept Libman's concept of the disease we are now considering as being a "subacute" rather than a "chronic" process. I gather that others have the same difficulty. I find that the last edition of Osler and McCrae's textbook of medicine includes two separate paragraphs; one is headed "Subacute bacterial endocarditis," and the other, immediately following it, is headed "Chronic infective endocarditis." But Libman makes it clear that by introducing the term "subacute bacterial endocarditis" he intends it to supersede the older name of "chronic

infective endocarditis," and to include the cases formerly put into this category. I must now confess to another inability to follow Libman when he uses the term "bacteria-free stage" of the disease as being synonymous with "healed stage." This writer speaks frequently of "healed and healing cases" in one and the same term. Now I can understand a "healed" case; there seems no doubt, largely as the result of Libman's own observations, that cases of septic endocarditis do occasionally undergo spontaneous cure, and that the residues of the old infection are found *post mortem*. I can also understand a "healing" case; in many chronic infections we get evidence, both during life and after death, that the lesions show constructive as well as destructive changes—to mention only pulmonary tuberculosis as one example. But to group "healed and healing cases" together under this single term seems to suggest some new type of case the criteria of which have been made by no means clear.

Libman admits that in the so-called "bacteria-free stage" of the disease some degree of pyrexia is often present, that anaemia is marked, that embolism goes on, that Osler's nodes and petechiae appear, that the patients get progressively more and more toxic and eventually die. But is not this passage from a more active stage of the disease to a more passive stage exactly what we see in some, indeed in a good many, other chronic infections?—in chronic pulmonary tuberculosis, again; in lymphadenoma; in chronic *Staphylococcus aureus* pyaemia; in syphilis; in malaria. In chronic septic endocarditis, as in these other diseases, patients not infrequently reach a cachectic stage in which the infection peters out, as it were, at the same time as the patient. The fight has been to a finish and neither party has won. Actually, the micro-organism has won, but only just. It can generally be demonstrated, though perhaps with difficulty, dug in and out of sight; and Libman admits this fact. I instance *S. aureus* infections of a chronic kind in particular as giving us a picture somewhat similar to that which is sometimes seen in chronic septic endocarditis. After a long and tedious illness the patient—cachectic, wasted, anaemic, enfeebled by his prolonged toxæmia—dies exhausted. Blood cultures have been sterile for weeks, even months, and the temperature has been at a much lower level than formerly. At first we were jubilant when these things happened. But they availed nothing, and we became aware that, though the fire of the interaction burned much lower, the disease was still progressing. We make a *post-mortem* examination perhaps; there is no obvious lesion; then, tucked away in some remote corner, we find a collection of inspissated pus—in the sheath of the psoas muscle it may be, or in the centrum ovale of the brain. From these old but still smouldering foci *S. aureus* is recovered in scanty numbers.

We must, of course, distinguish these so-called "bacteria-free" cases from the periods occurring earlier in the disease during which blood cultures are oftentimes negative, yet the patient is obviously in an active stage of his infection. There are possible reasons for these times of relative, or perhaps absolute, abacteriaemia. (1) They may be due to the covering over of the colonized bacteria in the valve cusps by a layer of fibrinous material, which for the time being prevents the paying out of cocci into the blood stream. (2) Or they may be the result of a rise in the bactericidal or other immunizing antibodies in the blood, so that the circulation is rendered sterile within the limits of the amount of blood taken for purposes of the culture. Doubtless there are other causes which are as yet hidden from us. Merryn Gordon has raised the question whether there may not be some filtering mechanism at work; he also reminds us of the great tendency of bacteria to yield to gravity. I should like to add the suggestion that in these cases something akin to the process of centrifugalization may go on, by which the bacteria, which are thrown into the circulation, are sedimented in various peripheral organs, leaving the blood stream relatively free. A close study of the cases makes it more and more apparent how innumerable are the embolic events that take place, and therefore how consonant with actual facts such an hypothesis may be.

DIAGNOSIS.

As the result of my earlier experience I was led to the view that to establish a diagnosis four cardinal points were necessary: multiple embolism, the signs of endocarditis, the isolation of a micro-organism from the blood, and pyrexia. Now that we are more familiar with the clinical picture, and have added certain other well recognized signs, the diagnosis becomes highly probable, though perhaps never quite certain, without the third, and certainly without the fourth, of these features. Thus, signs of multiple embolism, with endocarditis, in a patient having clubbed fingers and an otherwise unexplained anaemia, constitute a syndrome which scarcely admits of any other conclusion. In arriving at a decision, however, it is well to remember what a very grave prognosis a positive diagnosis carries with it in the present state of our ignorance of effective treatment. No doubt we shall be able, in years to come, to detect the disease at an earlier stage of its course, in which case we must be satisfied with less severe criteria. It may even be desirable to treat many patients as suspects, and remain uncertain, in the event of a satisfactory issue, if they were, or were not, larval instances of the disease.

In other words, we must strive to anticipate, rather than merely to recognize when present, the fully developed picture. There are other very suspicious combinations of signs and symptoms than that just given, but, granted that neither pyrexia nor a positive blood culture is essential to the diagnosis, it is impossible at present to construct a syndrome that does not include the feature of multiple embolism; and it is questionable if, once this process is in operation, we are not already too late in our efforts to arrest the disease.

We do not know, unfortunately, if there is an early pyrexial stage in the disease. We certainly do know that, though every case is probably at some time in its course pyrexial, pyrexial periods of one, two, or even three weeks are by no means uncommon during the later stages. Starling tells of an extraordinary instance of prolonged pyrexia lasting seventeen weeks. It is clear, therefore, that the absence of pyrexia at any particular time of observation by no means excludes the diagnosis.

Be the significance of negative blood cultures what it may, it is agreed that the diagnosis can frequently be made without evidence of bacteraemia at the time of examination, and, indeed, even though one or more subsequent efforts are also negative.

Libman has described localized tenderness over the lower end of the sternum with light pressure as a common symptom. I have found this present in several cases, but since I have also found it to be not uncommon in cases of severe anaemia, without evidence of endocarditis, I conclude that its importance in diagnosis depends upon the absence of this latter condition. Such tenderness is sometimes very marked, and very localized, in Addisonian anaemia.

MILD AND RECURRING CASES.

We are beginning to see light on the clinical side, and also on the side of gross morbid anatomy, in relation to the earlier stages of the disease, and this light may soon help in the histological and bacteriological sides by suggesting new lines of research. Several authors have described cases of mild bacteraemia, the cocci being of the same type as those associated with chronic septic endocarditis, and in which the clinical analogies with this latter disease are such as to suggest that they may have been abortive cases of it. Some of the cases have been followed for a period sufficiently long to make sure that they have recovered. It is tempting to consider them instances in which, as it were, the disease, as we usually know it, has missed fire.

Cases of recurrence, too, are being brought to light. I have seen two such cases. In one of these I was very doubtful, when the patient first came under observation, if I was not dealing with a case of septic endocarditis. There were signs of aortic regurgitation, and the patient was admitted to hospital on account of mild pyrexia, purpura, and arthritis. The spleen was palpable. Blood cultures were negative. The man was an ex-soldier with no history of any cause for his valvular disease. After two months' observation he was discharged, being given the benefit of

the doubt. He worked continuously as a postman for twelve months, feeling quite well. He was then admitted again to hospital, pyrexia and joint pains of an erratic kind having returned. The diagnosis of chronic septic endocarditis did not now admit of any doubt. In the other case there was again a clear interval of twelve months of good health between an attack of right hemiparesis associated with mitral regurgitation, slight pyrexia, clubbed fingers, and anaemia, and a second admission on account of a left hemiplegia, which was followed a month later by cerebral haemorrhage. It is possible, of course, that in neither of these cases was the interval between the two periods of observation sufficiently long to exclude the question of very protracted infection with unusually long remissions. But Libman and others have reported cases in which the interval between the attacks has been much longer. So that, unless we again take the view that the coccus can lie dormant in the endocardium over a period of years, we must consider the cases as true reinfections.

THE MECHANISM OF INFECTION.

When we turn to questions of *pathogenesis* we are faced with a whole series of unknown factors. We seem to know a good deal about the mechanism of the disease once the endocardial infection is established, and even our knowledge of the associated bacteria is by no means small, but the initial phases in the process of endocardial colonization are still hidden. We assume, perhaps rather too readily, that the source of the invading and infecting bacteria is one or other of the areas which for convenience we term areas of "focal sepsis." Such areas are conceived of as portals of entry of bacteria into the circulation. These areas have been recorded in many cases of the disease as though the relation between them and the heart infection is actually proved. Blumer has collected these records. It does not surprise us to read that the teeth and the tonsils head the list, that the female generative organs come next, and that the bronchial tract follows. But between the very common finding of salivary streptococci in apical tooth abscesses and the relatively uncommon finding of salivary streptococci in the endocardium there is a wide gulf to bridge. With the whole alimentary tract teeming with streptococci of this and of allied types it is quite a question if the area of focal sepsis is more than an epiphenomenon in the process of deep-seated infection.

If we now consider the mechanism of invasion of the infected valve we are equally in the dark. Does the coccus invade the valve from the coronary route or from the general blood stream bathing the outside of the valve? The argument for and against both routes, though old, is still open. Carey Coombs has quite recently convinced himself that, whereas the rheumatic virus reaches the cusps, and produces a valvulitis from within these structures, the bacteria in septic endocarditis attack them from the blood circulating around the cusps. The author's important work in connexion with the endocarditis of swine erysipelas is adduced in support of his views. But we still lack adequate demonstration of this difference of the modes of invasion in the two diseases. Whereas some authors adduce the fact of extra vascularization resulting from old inflammation as evidence that the coronary route is the likely one in septic endocarditis, others consider the scarring of the tissues resulting from the same process as liable to favour invasion from the surface. Certainly if analogy elsewhere goes for anything, it seems more likely that scarred tissues in this situation would be invaded from the surface rather than from the depths. But this latter hypothesis presupposes an initial septicaemia, or at any rate a bacteraemia, and probably of a massive kind. Of this there does not seem to be any clinical evidence: the disease is very insidious in its onset in nearly every case. Moreover, we are now faced with a difficulty with which the war cases have for the first time familiarized us—namely, that in many of these cases there appears to have been no old valve injury, or none the existence of which was apparent. Yet when we recollect that it is in the hearts which possess minor valve injuries, and not in those in which the valves are seriously damaged, that by preference the disease develops, we must

pause before we conclude that the aortic cusps in these ex-soldiers were above suspicion. In this connexion are to be considered the remarks already made concerning congenital defects, such as fusion of cusps, and the effects of strain upon such mechanically handicapped structures. It is rather a terrible thought, and yet it may well be true, that starting life with two aortic cusps instead of three determines a man's ultimate downfall by means of slow but inevitable sepsis, be the conditions of his life what they may. There are many persons in the possession of relatively good health who have minor degrees of valvular disease with good myocardial tone. Is there any way of ascertaining which of these are to be regarded as candidates for endocardial infection? At present the answer is that there is no such way. It is a point worthy of consideration, for if some observations arose by which such predisposition might be recognized, this would be a matter of great importance.

But if we are still much in the dark concerning the mechanism of the valve invasion and colonization, we are still more in the dark as to why it is that such feebly virulent bacteria gain so firm a foothold and pursue such relentless warfare. Is it mainly the general resistance that is at fault, or is it mainly the local tissue resistance? Does the coccus succeed in immunizing itself against the natural protecting substances of the blood and tissues? These are some of the questions that still await our answers. To which may be added the fact that the process of chronic ulceration in general in the body still holds some mysteries we have never yet explained.

RHEUMATIC AND SEPTIC ENDOCARDITIS COMPARED.

I have spoken of one great contrast between rheumatic endocarditis and septic endocarditis—namely, the great tendency to early and considerable involvement of the heart in the former, and the great freedom from intrinsic disease of the heart in the latter condition. I now turn to another great difference between these two diseases. In rheumatic heart disease we feel convinced that we are dealing with the work of a specific agent, and this conviction is not shaken by some doubt as to the causative nature of the infecting agent in certain cases of mitral stenosis. In septic endocarditis, on the other hand, we appear not to be dealing with a specific disease at all—that is, if we are right in our conclusions that the micro-organisms found to be associated with the disease during life and in the post-mortem room represent the only infecting agents present. I say this because, although I do not know that anyone has advanced evidence for such a view, it is just possible that all the bacteria associated with the pyaemic state in which the endocardium and various peripheral organs are concerned are of the nature of secondary infections, the primary infection being as yet unknown, and hardly suspected. But if we assume that the micro-organisms that we deal with every day in the disease are the sole causes of the infection, then we are faced with this striking fact—that the same disease picture may be produced by a variety of different micro-organisms. Even if it be argued that Rosenow's conclusions relative to the association of pneumococci with the disease are not yet accepted, and that the gonococcus cases are not really chronic (though two patients in Thayer's series lived over six months), there still remain, in addition to the streptococcal cases which bulk so largely in the whole number, the cases due to Pfeiffer's bacillus. Between these last-named cases and those due to streptococci there cannot, so far as I know, be distinguished any difference either clinically or by naked-eye morbid anatomy. And yet we know of no affinities whatever between the streptococcal group of micro-organisms and the group of which Pfeiffer's bacillus is a prominent member. But the lack of specificity in the disease would appear to go further than this. Individual cases within the streptococcal group show a strange lack of uniformity when investigated serologically. Kenneth Stone, working in Gordon's laboratory upon complement fixation in streptococcal infections, found that the serum from cases of chronic septic endocarditis gave positive reactions with the homologous cocci obtained by blood culture, with a titre even as high as 1 in 4,000, but that this same serum gave very little cross-fixation

with heterologous cocci (that is, with cocci obtained from other cases), and frequently no cross-fixation occurred at all. It would almost appear, therefore, as though the cases, far from being specific as a group, are specific only as individuals. The bearing of all this upon the difficulties of immunotherapy is obvious.

There is, it seems to me, still another striking fact in connexion with the bacteriology of the disease, and that is the absence of any evidence that more than one strain of streptococcus is present in the same case. Nor has any case yet been described in which streptococci and Pfeiffer's bacillus have both been present. If the source of the endocardial infection is an area of focal sepsis, as is commonly supposed, it seems strange that there should not occur in the vegetations, and in the circulation, at least occasionally, more than one strain of these common invaders. That this is so strongly favours the view that the streptococci are performing the role not of secondary, but of primary, infections.

TREATMENT.

I shall not stay to deal with the treatment in cases of syphilitic disease. In rheumatic endocarditis the treatment is that of acute and recurring rheumatism. Into this again I shall not go, reserving my time rather for considerations that apply to septic cases.

When faced with a case of acute infective endocarditis the treatment is that of the septic focus, when this is present, and also of the pyaemia complicating it. Immunotherapy has perhaps a slightly better chance of rendering assistance here than it has in chronic cases; it should therefore be given a thorough trial. The rogue at present is the process known as immunotransfusion, and it is perhaps too early yet to say what the results of this method are. All cases should, whenever practicable, be treated in the open air.

I now turn to the treatment of the chronic type of septic endocarditis.

In one of his most recent communications Libman is good enough to credit me with being the first to emphasize the importance of prophylactic measures in the treatment of this disease. Although there is no doubt he is correct in this, he is kind enough not to point out the paucity of the constructive suggestions which I made under this heading in 1909. I dealt almost entirely with the importance of treating the various forms of oral sepsis, and with considering certain methods by which the streptococci of the intestinal tract might be kept from transgressing the barriers which usually suffice to keep them outside the blood stream. That these measures of preventive treatment are of more importance in patients who have residual endocardial lesions, of whatever origin, than in other persons, will scarcely be questioned. Yet it is by no means an uncommon experience to find devitalized teeth with demonstrable apical sepsis in these patients. The well established sequence of a septic endocarditis arising as a direct consequence of the extraction of such teeth under local anaesthesia, together with the isolation of a salivary type of streptococcus from the blood in such cases, should surely lead to a rule of treatment by the observance of which no dead teeth and no obvious pyorrhoea are permitted to be present in such patients. It is unfortunate that a recent obsession in regard to sacrificing all teeth that are in the least degree suspicious in every patient has militated in the public mind against such a preventive measure being followed in selected cases. The question of septic tonsils is much less simple, because the criteria by which we judge these organs are notoriously vague, whether we consider the matter from the point of view of the general physician, the throat specialist, or the bacteriologist. Tonsils are sometimes condemned because cultures taken from them grow streptococci of the haemolytic, long-chained, or pyogenic type, on the ground that this is a more highly pathogenic type than others. But it is obvious, from what has been said, that in the present connexion such a finding should not condemn the tonsils any more than if the cultures yielded the viridans, short-chained, or salivary type; if, indeed, the condemnation should be as strong. The present state of our knowledge of

the streptococcus group makes the statement so often occurring in bacteriological reports, that "cultures from the tonsils give no pathogenic strains of streptococci" of no service when we are considering the prophylactic treatment of endocarditis. Until we have more definite guidance along these lines we shall probably act most wisely by deciding the question of the enucleation of tonsils on their general merits rather than upon their bacteriological content.

In the direction of "intestinal disinfection," so called, prophylaxis gropes in even greater darkness. There are problems here which we have scarcely begun to probe, but to think that security from subinfection lies in merely avoiding constipation, good though such advice may be, is to invite a rude awakening. We do not even know for certain that subinfection from the bowel bears any definite relation to the quantitative content of streptococci in this situation, or to the relative proportions of streptococci to coliform bacilli, though both of these things are generally taken for granted. Is it not a fact that we not infrequently make use of these and analogous findings to support a scheme of therapeutics, when the premises upon which such a scheme is based are quite lacking in proof? The suggestion of Besredka and others, that it might be well to employ antigens by the intestinal route in cases in which it is presumed that the initial interaction resulting from infection takes place in this situation, has scarcely received so thorough a trial as it deserves. We may get some help from such a trial. We may also get some help from well controlled observations relative to the effect of different diets upon the intestinal flora. Up till now very little work has been done on this point.

The injunction against undue strain, both physical and emotional, in persons having evidence of slight valvular defects, though theoretically indicated, is not likely to carry much weight. Yet it becomes our duty to give such advice in view of all the facts.

Curative measures now call for consideration.

Chemotherapy, despite the enormous number of drugs that have been tried at one time or another, and which I will not stay to catalogue, has so far been of little real help; and this is true by whatever route the drugs have been used. Yet it must not be concluded that we shall not ultimately find some remedy of a chemical nature which shall assist the tissues in their interaction with the infecting agent; for the crude notion that a chemical remedy can only help in microbial infections by a direct bactericidal action is, of course, no longer tenable. Of late years new claims have been made on behalf of arsenic, and especially when given intravenously. Needless to say, when the arsenobenzol series of drugs arrived they were given full trial in septic endocarditis, but, so far as I can find, without any permanently good results. Of immediately serious results by way of cerebral embolus I saw not a few, and I gather this is the experience of others. I have given Capps's sodium cacodylate treatment a very thorough trial, but have so far seen nothing to lead me to the conclusion that the patient has benefited more than is usual with so good a haematinic remedy as this proves to be in many infections. Capps gives daily injections of the drug intravenously, beginning with 1 grain and increasing gradually up to 5 grains. In all I have treated twelve cases, and I have in half of these given larger doses than Capps has recommended. I have also, following Capps's suggestion, followed up the treatment for many weeks. There is certainly this to be said for the drug, that it is singularly free from ill effects.

I think it is clear, from all we know of the disease, that recovery, whether by the aid of remedies used or occurring spontaneously, must of necessity be very slow if it is to be safe. When we remember the characters of the vegetations, and the ease with which they separate off as emboli, it is obvious that any remedy which acted as quickly as, for example, a *grand lavage* of the blood stream by some reputed blood antiseptic, would endanger death from cerebral embolism. And when we recollect the deep colonization of the infecting micro-organisms in the valves, it is equally obvious that no such lavage is likely to dislodge or kill these, seeing that they are to a large extent outside the direct blood stream.

As little credit can be given so far to measures of immunotherapy as to those of chemotherapy. And this applies to all the permutations and combinations of antigen and immune serum that the mind of the immunologist—not a mind lacking in fertility and inventiveness—has so far devised. The latest of these is immunotransfusion, which, though it is claimed that this method raises the bactericidal power of the blood, has not so far been more successful than other methods. A method of treatment which raises the bactericidal power of the blood as tested outside the body gives us no guarantee that it will do this inside the body; or, if it does, that the rise in bactericidal power will be sufficient, within the limits of the method, to turn the scale against the infecting agent and in favour of the patient. These things would be very puzzling did we not know of stranger facts—the fact, for example, that, apart from any immunotherapy whatever, the blood in many cases of chronic septic endocarditis is extremely rich in certain antibodies specific to the micro-organism isolated from the patient's circulation. And yet such patients may, all the time, be losing ground slowly but surely.

In opening a discussion upon chronic septic endocarditis at Cambridge in 1920, when speaking of curative treatment, I raised the point as to whether we ought not to deal with these patients on much the same lines as we follow in cases of chronic tuberculosis, bearing in mind, of course, the difference in the organs affected. I have of late years concentrated more and more upon non-specific measures, as for a disease of "low resistance." I treat as many cases as possible in the open air, with sunlight, natural and artificial. I supplement this by a long series of intravenous and intramuscular injections of sodium caedylate. Sometimes I have found, as others have, that simple transfusions of blood are of considerable help. These are the only measures I yet know of that seem to give the patients the best chance of overcoming their usually intractable infection.

It remains for me to thank you, Sir, and the Fellows, for your patience in giving me your attention during the delivery of these lectures.

CHRONIC PYLORIC OR DUODENAL ULCER: POSTERIOR GASTRO-JEJUNOSTOMY WITH JEJUNO- JEJUNOSTOMY.

BY

G. GORE GILLON, F.R.C.S. Ed.,
RYDE, ISLE OF WIGHT.

The operation of a no-loop posterior gastro-jejunostomy has had a long trial, and, although the ulcer heals, the after-history of these patients, as regards well-being and comfort, is in a very large number of cases unsatisfactory.

A-C' = $3\frac{1}{2}$ in.; A-A = 3 in.;
B-B = $2\frac{1}{2}$ in.; C-C' = $1\frac{1}{2}$ in.;
P-V = $3\frac{1}{2}$ in.

The new pylorus is at A,A, and the dotted line along the duodenum from Vater's ampulla (V) to the jejunal opening at C,C' shows the course of the secretions from liver and pancreas to join the food stream issuing from the stomach at A,A. The two tubes of jejunum, marked by

THE MAKING OF A NEW PYLORUS.

A modification of this operation¹ is jejuno-jejunostomy, done at the same time as the posterior gastro-jejunostomy so as to ensure the making of a new pylorus, by which the status quo ante as regards the physiology of the parts concerned is brought about.

The illustration represents a horizontal section of stomach and bowel after the operation is completed; for clearness' sake the gastro-ecolic oval omental attachment is not indicated.

arrows, function at the first part of the duodenum. C' is at a point $3\frac{1}{2}$ in. below the new pylorus (A,A), which is the precise distance that the normal Vater's opening (V) is situated from the normal pylorus (P). A 10-inch loop of proximal jejunum, brought to the surface, gives enough bowel to work with, and no kinking ensues. The extra time required for the second anastomosis is only some fifteen minutes.

In effect, the whole physiological plan of the pylorus and the duodenal exit of the digestive fluids is simply removed some inches to the left. The gastric anastomosis is 3 inches and the jejuno-jejunal $1\frac{1}{2}$ inches long. The patients enjoy very good health afterwards, with no unpleasant after-effects.

I have just learnt that one of the surgeons of the Mayo Clinic has begun to do this operation and intends to report his results.

GANGRENE IN AN INFANT SEVEN DAYS OLD: RECOVERY.*

BY

W. R. GROVE, M.D. Cantab.

A PRIMIPARA, aged 33, who had had no miscarriages and been married two years, was, on January 30th, 1925, confined naturally, after an easy labour of six hours, of a female child. On the morning of February 5th the child's right leg was found blue from the knee downwards. The cord had separated the day before, and the umbilicus was a perfectly clean scar without redness; there was no rise of temperature, and the heart appeared normal. There seemed little pain, only a slight whimpering when the limb was handled. The leg was kept warm in cotton-wool, and the blueness gradually decreased downwards, until in about ten days there was a line of demarcation straight across the dorsum of the foot at the base of the toes, but on the sole of the foot it extended in a triangle nearly to the point of the heel. This gangrenous area was dry. It was decided to leave events to Nature, but, with the experience of gangrene in the old, the parents were told to expect a weary waiting of months for the separation of the slough. The mother was unable to nurse the child, but on undiluted milk it thrived apace, so that in each week from the beginning there was a gain in weight. On March 18th I was amazed to hear that the toes had separated, the factor of the child's growth away from the dead part never having entered my head. Within three weeks afterwards, very little more than two months from the onset, the foot was completely healed, the triangle on the sole of the foot having been only skin.

An attempt to get a photograph in the gangrenous stage failed from movement, an indoors time exposure being necessary. But the accompanying illustration in the healed state, when the child was 7 months old, shows the want of toes and the ridge on the sole of the foot. The separated toes have been placed in the Pathological Museum, Cambridge.

It is almost certain that the gangrene was due to an embolus caught at the bifurcation of the anterior and posterior tibial arteries, and that the circulation was re-established except in the toes and sole of the foot.

As to the origin of this embolus there must be some doubt; it is possible that it came from the umbilical vein, by way of the ductus venosus, inferior vena cava, and the right auricle, thence either through a patent foramen ovale, or into the pulmonary artery and by the ductus arteriosus

* A paper read before the Cambridge Medical Society, October, 1925.

to the aorta, and so to any artery of the body. Osler has recorded a case of hemiplegia *in utero*; the mother had typhoid fever, and the embolus was derived from the placenta and would have taken some such course. While this route in my case is theoretically possible, from a practical point of view I do not think it can hold, otherwise emboli in various parts of the infant's anatomy would be much more common than they are. It seems to me that such a rare occurrence is likely to be caused by some abnormality, and I would suggest an abnormal umbilical artery on the right as the most probable. The normal hypogastric artery arising from the internal iliac gives off several branches before it ends as the umbilical. In the separation of the cord, should that artery become detached from its moorings, a clot against the blood stream could not get beyond one or two branches. But if the umbilical was a separate one, derived from the common or external iliac, the giving way of this might easily shoot out the clot into the stream to the leg, and, being without branches to moor it, the elastic action would be the stronger.

With the help of Neale's *Digest* and the *Index Medicus* I have hunted up the cases of infantile gangrene in English. The great majority are in older children, and occur as part of other diseases, notably sepsis or syphilitic arteritis; or in Raynaud's disease, where the areas are multiple and smaller. One case only have I been able to find that at all approaches this case.¹ In that the child when first seen was 2 weeks old and died the next day. We are not told the date of the first appearance, but it was supposed to have begun below the knee. At the examination the left leg and thigh were affected. *Post-mortem* examination confined to the femoral artery showed no signs of embolus of that vessel.

I am tempted to add one case which, though inappropriate, is worth resurrection.² The doctor was called to see a woman, aged 40, who had three children alive; these births had been followed by three miscarriages, and being now pregnant she was anxious to have a live child, as she thought her health would be improved by nursing. She was obese, but the doctor felt sure he heard a faint foetal heart, so that he was able to reassure the parents. On making a vaginal examination he was surprised to find already a breech presenting, and still more surprised to bring down two gangrenous legs, the integument coming away in his hand. Meantime the woman had one pain, and a baby which cried lustily and lived for twenty-four hours was shot into the world! The address of the recorder is given as New York.

MEDICAL, SURGICAL, OBSTETRICAL.

STRIDOR ACCOMPANYING MEASLES.

DURING epidemics of measles in recent years few serious cases have occurred, but last winter the type was much more severe. Stridor appears to be one of the more rare accompaniments, for the following case has been the only one seen in the last two or three hundred cases. Ker, in his *Manual of Fevers*, mentions the possibility of measles being confused with diphtheria when laryngeal symptoms occur, and Still, in his *Common Disorders and Diseases of Childhood*, quotes a similar perplexity to that which presented itself in the following case.

I first saw X, a boy aged 5, at 5.30 p.m. on March 4th. Ten days previously he had been in contact with a child who subsequently developed a typical measles rash. His eyes were heavy and he looked "measly." His temperature was 101°, pulse 100. There was no abnormality in the throat or chest, no Koplik's spots could be seen, nor was any rash present.

The following day he was much the same, but when seen on March 6th at 11 a.m. the temperature was 102°, pulse 120, respirations 40, and he had developed a croupy cough without pulmonary signs. The tonsils were now considerably enlarged, but no exudation or membrane could be seen. In addition to this he had the seemed stridor, his cheeks were slightly cyanosed, and although he seemed bright in speech he showed no inclination to sit up. At 6 p.m. the stridor seemed more marked and his pulse and temperature were unchanged. As by 10 p.m. there was still no

sign of a rash or confirmatory evidence of measles in the shape of Koplik's spots, 4,000 units of diphtheria antitoxin was injected subcutaneously, hot applications to the throat were given, and a steam kettle ordered.

On the following day at 10 a.m. his temperature was 103.4°, pulse 128; the stridor was, if anything, slightly less marked, and a few macular spots were visible on the face and behind the ears. By 2 p.m. the rash on the face was quite definite and his temperature had fallen to 102.5°, whilst by 9.30 p.m. the temperature had declined another degree and the case was quite obviously one of morbilli.

Subsequent progress was unevenful. Although the breathing continued noisy for some days, the temperature fell to normal on March 8th, and in spite of the severity of the attack he was able to get up ten days from the first onset of his symptoms.

On examination for Klebs-Loeffler bacilli a swab of the throat proved to be negative.

NOVASUROL AND HYPERTONIC SALINE IN CHRONIC OEDEMA.

REFERENCE has been made in these columns to the diuretic properties of novasurol and its beneficial dehydrating effects on oedema of a generalized type. There are certain advanced cardiac cases, with possibly a recurrent attack of "water-logging," where the effect of the drug, given alone, may not be so gratifying—cases where digitalis has done its utmost in steadying rhythm and increased output—and yet the oedema of arms, legs, and cavities persists.

It seems likely that the prolonged malnutrition of the capillary walls makes it difficult for the tissue spaces to yield up their excess of fluid into the "active" circulation under the osmotic conditions prevailing. In such instances I have found that the addition of 20 to 30 c.cm. of 2 per cent. saline to each dose of novasurol (doses gradually increasing from 0.5 to 2 c.cm., given intravenously at intervals of four or five days) produces a markedly increased diuresis. By such means the output of urine—controlled by injections of the drug alone—has been increased by as much as 20 to 30 oz. in the twenty-four hours following injection.

It seems that the hydraemia thus induced is of sufficient duration to enable the kidneys to excrete (under the influence of novasurol) the additional urine before osmotic equilibrium is reinstated in the tissue-capillary areas. Moreover, the common complication of diarrhoea has been absent—a fact which recalls Sir Leonard Rogers's treatment of Asiatic cholera.

POISONING BY THE PRODUCTS OF COMBUSTION OF TOBACCO APPLIED TO THE SKIN.

LATE one evening we paid a visit, urgently requested, to a small girl, whom we found lying in bed asleep; her skin was pallid, and although it was a hot night in June she seemed very cold; the pulse was very weak, and the breathing infrequent and sighing. When aroused the eyes turned upwards, and she was slightly delirious, with gentle retching.

The illness had commenced an hour before with severe vomiting; it followed a vigorous rubbing of her trunk and limbs with a mixture of writing ink and scrapings from an old tobacco pipe (dottle). This her mother had done to cure a very diffuse attack of "ringworms."

Having given the child a quick scrub with hot water and soap, we had the pleasure of seeing a very rapid improvement in vasomotor tone; she would fall asleep as if from intense weariness, but could be progressively more easily aroused. The next day she seemed well, and has remained so.

No doubt most doctors could creditably pass an examination on the physiological action of tobacco, but many, perhaps, will scarcely have realized the great potency of these products even when merely inhaled. Everyone has heard that a dog can be killed by a drop of nicotine placed on the conjunctiva; and one has felt oneself sinking in the swamps of Acheron after embarking upon the adventure of a first smoke, and that of "black shag." Moreover, interest attaches to the phenomenon of absorption of drugs by the skin. Wherefore we feel that this case should be recorded, as it may be appreciated by

pharmacologists, one or more of whom may perhaps be inclined to tell us the name of the essential noxious substance found in the foul bowl of a well used tobacco pipe.

Luff refers to a case of nicotine poisoning by skin absorption, but is nicotine contained in the dottle?

CLINICAL AND SCIENTIFIC PROCEEDINGS.

OXFORD DIVISION.

THE second meeting of the year of the Oxford Division was held in the Radcliffe Infirmary on March 24th. In the absence of the chairman, Dr. DUIGAN presided over an attendance of forty members.

American Methods in British Hospitals.

The administrator of the Radcliffe Infirmary, Mr. A. G. E. SANCTUARY, M.A., read a paper on the development of British hospitals on American lines. He wished to see in-patient hospital facilities for all three classes of the community. At present there were not enough beds for the poorer classes, practically none for the middle classes, while the richer members of the community were not satisfied with the existing extravagant nursing homes. The problem should be tackled as a whole, and the quickest and best solution would be for the voluntary hospitals to provide accommodation for every class. The first class of patient already contributed a good deal; the second class, by an insurance scheme, could pay more than the actual cost of maintenance and treatment; and the third section of the community would be glad to pay an amount for the advantages of a fully equipped hospital that would leave a handsome profit. Mr. Sanctuary gave it as his opinion that this form of development of British hospitals would be good for all classes of the lay community, for specialists, and for private doctors, and would make the hospitals safe for all time.

Pachymeningitis Haemorrhagica Interna.

Dr. WATRS read notes of a case of pachymeningitis haemorrhagica interna which had recently been under his care in the hospital.

The patient was a woman, aged 76, who was quite well until two months before admission. She then began to complain of headache, deafness, giddiness, and defective vision. These continued for about five weeks, when her doctor sent her to the Radcliffe Infirmary. For ten days after the patient's admission to hospital there was very little change in her condition. Persistent and severe occipital headache was the chief symptom; she was quite rational. At the end of this period, however, she became definitely "mental" and rapidly sank into a stuporous condition and died in about a fortnight.

At the necropsy, on opening the skull, the inner aspect of the dura showed a marked haemorrhagic layer. There was oedema of the pia mater, and the dura was in a stage of organization, and both occipital lobes. The dura was : and anterior fossae. The posterior fossa was free. Over the vertex the pia was stained yellow. The middle cerebral arteries were thickened and there was some increase in size of the lateral ventricles.

Dr. MALLAM showed a case of lupus erythematosus and a case of urticaria pigmentosa.

Modern Treatment of Deafness.

Dr. GEORGE CATCANT gave an address on the modern treatment of deafness. He began by remarking that it had to be remembered that otology was one of the youngest branches of science, and only of late years had anything begun to be done for the deaf; the knowledge gained by specialism had still to filter through till it became part of the ordinary curriculum of the medical student. Yet prevention was beginning to play its part. Already there was a great change in the type of case seen in adult life; a few years ago the mastoid operations that had to be done for chronic ear discharge in order to save life were infinitely more numerous than at the present day, and no doubt that was because of the greater care taken of the ears during the course of measles and scarlet fever, and also because of the more frequent removal of adenoids. Chronic catarrhal otitis media was undoubtedly the com-

monest form of deafness, and yet it was the only form which was not hereditary; and might be prevented by the removal of adenoids and enlarged tonsils in childhood; catarrhal otitis media ought to be curable if treated in the early stages. A few years ago the presence of an intact drum and ossicles was considered an absolute essential to hearing, and a large number of the laity, even the well educated, still raised strong objections when the question of paracentesis was mooted. It was now known, however, that the sounds reached the inner ear by means of the round window, and so long as that was healthy it did not matter so much about the drum. For nerve deafness hitherto there had been no treatment. The sufferers were told to try various drugs; to stop smoking; not to worry; to lead a godly, righteous, and sober life in the future, if they had not done so in the past; and, above all, not to waste any more money on doctors, as no one could do them any good. Nor was the prospect any more pleasing when one turned to the treatment of chronic otitis media: Sir William Milligan had given it as his opinion that there had been no substantial progress in the treatment of adhesive catarrh of the middle ear during the past twenty years. Dr. Catheart said that for many years he had been of the same opinion, and had got tired of having to tell so many patients, after the classical remedies had failed, that nothing more could be done for them. A few years ago, however, he heard, through an old patient who had been successfully treated by it, of a new method of treating chronic progressive deafness—namely, the electrophonoid method originated by M. Zund-Burguet of Paris. The electrophonoid was an instrument which reproduced the sound vibrations of the whole gamut of the human voice, and thus gave a physiological stimulus to the ear. The sounds produced were of varying quality and were variable at will; they were transmitted to the ear by telephonic receivers which could be adjusted to the sensitiveness of each ear. Finally, a secondary current, producing a gentle short-wave vibratory massage of the ear, was superimposed on the primary one which made the sounds; it was to this double action that the successful results were attributed. This method of treatment laboured under the disadvantage that it was not possible to tell from any tests made beforehand whether it would be successful or not. There was a factor in deafness as yet unrecognized, the presence—or it might be the absence—of which determined the result. The usual course of treatment consisted of thirty sittings, but on account of this unknown factor it was necessary to give a preliminary course of twelve sittings to find out whether it was worth while to continue or not. The speaker had recently published, in detail, a list of 100 cases, of all ages, treated by this method, 34 suffering from nerve deafness, 33 from chronic otitis media, and 33 from otosclerosis; they had all been pronounced by other otologists to be hopeless and incurable. By the electrophonoid method of treatment 81 per cent. of the cases of nerve deafness improved, 67 per cent. of the cases of chronic otitis media, and 55 per cent. of the cases of otosclerosis. Thirty-six of the 100 cases also suffered from noises in the head, which ceased after treatment in 72 per cent., while in the remainder they were much lessened. Dr. Catheart was strongly of opinion, therefore, that the electrophonoid method, when properly carried out, was the most important advance in recent years in the treatment of chronic deafness and tinnitus.

Reports of Societies.

RICKETS.

At a meeting of the Manchester Medical Society on March 31st, Professor A. H. BURGESS, the President, in the chair, a discussion on rickets was held.

Dr. T. A. GOODFELLOW briefly summarized the research during the past fifteen years, prefacing his remarks with a short statement of the views held upon the etiology and treatment of rickets prior to 1912. He referred to the discovery of the necessary food factors in that year by Gowland Hopkins as the starting-point of the intensive research of recent years, and criticized the various theories as to the causation of the disease. At the present time

these appeared to be concerned chiefly with hygienic and diet, the importance of the former being stressed by the Glasgow school and supported by the work of Margaret Ferguson under the Medical Research Council. Recent work—especially that of the Mellanbys, of the British researchers in Vienna (published in 1923), and of the many observers who had been noting the effects of the ultra-violet rays upon animals and foodstuffs as well as on rickety children—had considerably narrowed the field for discussion. Most observers now agreed with Mellanby that the three essential factors in the etiology of the disease were: an organic factor in the diet which was concerned in the calcification of bone; light, either direct sunlight or radiations from the mercury vapour quartz lamp; and the amount and correct balance in the diet of the salts of calcium and phosphorus. Two recent communications (JOURNAL, March 20th, pp. 515 and 519) by E. Mellanby and L. G. Parsons were cited as producing valuable evidence of the association between rickets and enteral conditions in infancy, and, in the latter, of the part played by irradiated cholesterol in the cure of rickets.

Rickets in the First Two Years of Life.

Dr. CATHERINE CRISHOLM dealt with the manifestation of rickets in the first two years of child life. Theories of the causation of rickets were discussed and attention drawn to the frequency with which child after child in one family, out of proportion to its neighbours living under similar conditions, contracted rickets. She thought, therefore, that attention should be paid to a possible familial tendency. Personal idiosyncrasy, as evidenced by one of the twins developing rickets when housed and fed like its brother, had also to be considered as a factor. The weaning time in 200 cases of rickets entering the hospital at various ages showed a largely predominating number of cases weaned in the first two months. A comparative chart of 75 children showed the ordinary weaning time of the Manchester mother. Of these infants a certain number were weaned before the age of 2 months; 75 per cent. of these early weaned cases developed rickets, as compared with a 26.6 per cent. case incidence in the total number. Whether rickets was primarily a disease of bone, one symptom of an entity, or merely a symptom or sequela of wasting diseases, the bone change was the main feature of the condition found. In considering the diagnosis of rickets emphasis was therefore laid on the need for a combined radiological and clinical examination. The classical clinical symptoms alone were undependable. Two types of cases of rickets were found, and were well described, by Wimberger. Clinically there was a tendency to underestimate the amount of bone change in mild cases of the first or florid type, and radiologically in the second or passive type. As to the general incidence of rickets in the population, Thomson of Edinburgh had stated that between 1895 and 1900 over 50 per cent. of the children attending the Hospital for Sick Children under 3 years of age showed unmistakable signs. Paterson found 1.2 per cent. of active rickets in London in April, 1925; 32 per cent. had had rickets. Helen McKay, in a different investigation, found at least 8 per cent.; all but one, however, were slight cases. In an examination of 75 cases of unselected Manchester children who had never attended infant welfare centres, 26 per cent. of active rickets was found; two-thirds of the cases were well marked, and at least 46 per cent. showed radiological signs of having had rickets. Of Paterson's London patients 52 per cent. were taking oil regularly; of the Manchester district patients only five children—that is, 6 per cent.—were having oil. The treatment of rickets was obviously the supply of the chemical constituents needed in the form or with the medium which helped in their absorption and under conditions which enabled them to be used to the best advantage. Various attempts had been made to irradiate food lacking in vitamins, or to isolate the vitamin factor and add it to the diet. At the Babies Hospital infants had been radiologically examined and watched on different lines of treatment. Unfortunately infants could not be regulated as laboratory animals, and intercurrent troubles were always arising to spoil the experiment. But apparently the results at present were as follows. With a well balanced diet alone, rickets might

be healed, even when advanced, but it took a long time, during which the infant must be given exercise, yet prevented from putting weight on weak limbs. The healing was irregular as well as slow, and relapses occurred. Massage was not of much value in the actual healing of rickets where bone lesions were marked. The muscles might improve and the child learn to walk, progress being apparently satisfactory, but the bones healed but slowly. Cod-liver oil was the most dependable single agent for cure, and in combination with Parrish's food was the most reliable form of treatment. Mercury vapour light certainly helped to cure, particularly the lethargic type with flabby musculature or the small atrophic type. Both types of infants seemed to be stimulated by the rays and to respond well. The use of cod-liver oil with violet rays was an excellent and quick combination. A combination of food, massage, light, and oil certainly produced the quickest and best result in the cases selected in the autumn of 1925. The best treatment was cod-liver oil and natural sunlight, even in Manchester, when the summer was good and the infants were properly fed, clothed, and exposed under suitable conditions.

Rachitic Deformities.

Mr. HARRY PLATT said that to the surgical mind rickets was essentially a problem in the prevention and cure of deformity. Many of the efficient measures used to-day in the treatment of rachitic deformities had undergone little modification since their introduction many years ago. Operative intervention in rickets was now tending to be placed on a sounder basis. A deformity corrected in the stage of florid rickets was always likely to recur, so that some criterion of the activity of the disease was needed. This had now been provided as a result of the study of radiograms of the epiphyses in the various stages. In the infant the radiological index of activity had been completely established, but was not so definite in the older child or adolescent. A more careful clinical examination of patients presenting the syndrome of late rickets had revealed the occasional occurrence of so-called "renal rickets," in which the operative correction of deformities was always followed by disaster. Such experience emphasized the importance of a careful examination of the urine and an estimation of the kidney function. Rachitic deformities which called for the attention of the surgeon usually affected the lower limbs. Of these, there were three main types—bow-legs, knock-knee, and coxa vara. Bow-legs was essentially a deformity which showed a tendency to spontaneous rectification; it was rarely necessary to employ any special measures, and still less necessary to operate. For the extreme degrees of deformity in older children, tibial, or more rarely femoral, osteotomy was occasionally needed. Manual osteoclasis was possible when the bones were soft, but at this stage spontaneous cure could be expected in the majority of cases. Anterior bowing of the tibia was a deformity often better left alone. Its correction by operation in the extreme cases was not easy. Knock-knee, in contradistinction to bow-legs, was usually a progressive deformity, and once initiated tended to increase long after rickets had healed. As it was determined chiefly by weight-bearing, in the early stage this should be prohibited wherever possible. Under the exceptional conditions of an open-air hospital moderate degrees of rachitic knock-knee would disappear without any form of splinting. In ordinary hospital out-patient practice it was usual to apply a corrective walking appliance, the best form being the classical knock-knee brace of Thomas. A great many cases of knock-knee in older children, however, came for operative correction, and on the whole the results of femoral osteotomy were exceedingly good, provided the after-treatment was adequate. In the younger patients, after femoral osteotomy, the limb could be treated by immediate fixation in a plaster-of-Paris spica. In the adolescent and young adult it was desirable, however, to employ traction on a Thomas splint for as long a period as possible. This minimized the angulation and overlapping of the fragments, and helped to ensure rapid union. Refracture after a femoral osteotomy was not an uncommon experience in this operation. In the older patients it was sometimes difficult to reproduce the full mobility of the knee-joint in a short time. Rachitic coxa vara could be

almost ignored, as it was chiefly a deformity appreciable only in radiograms; it invariably underwent spontaneous cure. Deformities of the arm possessed little surgical interest. Deformities of the chest were important, and once fully developed could rarely be corrected, although general benefit was gained from regular gymnastic exercises. In the production of spinal deformities rickets was a subsidiary or negligible factor.

Renal Rickets.

Dr. G. V. ASHCROFT, in a paper on renal rickets, presented the results of an inquiry made at Anecoats Hospital into the association of rickets with renal disease. One typical case was described in detail with the results of urea tests, the deformity and x-ray appearances being demonstrated by lantern slides. In renal rickets the clinical picture was one of the onset at puberty of deformities of the late rickets type, associated with a profound muscular asthenia, pallor, stunting without infantilism, a low specific gravity urine, pale in colour and containing albumin, a notable absence of oedema and cardio-vascular change, and negative Wassermann, Loewi, and Goetsch reactions. The x-ray picture was one of rarefaction and porosis, enlargement and lack of cortex, associated with some rachitic changes at the epiphyseal line. The necropsy showed chronic interstitial nephritis associated with fibrosis of the suprarenal gland and an inactive thyroid gland. The degree of renal involvement roughly paralleled the degree of clinical and x-ray abnormality. It was to the association of the typical clinical picture, the typical x-ray picture, and deficient renal function that the term "renal rickets" had been applied. The risk of uraemia following operation and the poor result obtained by osteotomy in such cases was stressed. In view of the frequency of the condition and the ease with which it might be overlooked, it was suggested that before an adolescent with bone deformity came to operation renal function tests should be performed. Of the 24 adolescents with rickets investigated, 33 per cent. showed definite renal inefficiency and 54 per cent. revealed some renal defect. Sufficient evidence had been found to warrant the suggestion that while the kidney lesion was responsible for certain of the findings, such as albuminuria and death from uraemia, the greater part of the condition might be due to fibrosis of the suprarenal gland.

MANIPULATIVE SURGERY.

At a meeting of the Brighton and Sussex Medical-Chirurgical Society on April 1st, Mr. H. J. WALKER, the President, in the chair, a paper was read by Dr. JAMES MENNELL on the principles and practice of manipulative surgery, followed by a demonstration of technique. Manipulative treatment had, he said, suffered a set-back owing to the too rigid adherence to Hilton's teaching of rest and pain. The mistake had been made in the past of failing to realize the essential difference between movement and function—a distinction ably drawn in the work of Lucas-Championnière. Dr. Mennell dealt with the prophylactic treatment of the results of injury, and then with the treatment of cases where either prophylaxis had not been practised or had failed. He drew attention to the danger of putting a joint through its full range of anatomical movement when limitation of movement was marked and of long standing. The desirability was emphasized in these cases of merely passing the first dead point, and then allowing the patient to regain the increased freedom of movement before an attempt was made to gain a yet wider range as the result of subsequent manipulation. The necessity for after-treatment was also pointed out. Dr. Mennell pleaded for a more scientific consideration of lesions of joints of the back, condemning the practice of dubbing every aching back "neurasthenia."

A case of lichen planus with scalp lesions was shown by Dr. WINKELRIED WILLIAMS, who said that this association was usually considered very rare. Whitfield and others had shown cases at the Royal Society of Medicine recently, and it had been suggested that if lesions in the scalp were looked out for they would be found more commonly. Out of twelve cases recently seen scalp lesions were found in two. The case shown was the most extreme of these.

Reviews.

ARABIAN MEDICINE.

To the philosopher and thinker, as well as to members of the medical profession, the two scholarly volumes on *Arabian Medicine and its Influence on the Middle Ages*,¹ by Dr. DONALD CAMPBELL, will afford much profitable and intensely interesting reading.

The author appears to be little known among medical historians, and describes himself on the title-page merely as captain, late R.A.M.C., and formerly Indian Army Reserve of Officers; but these volumes disclose him to be a profound and erudite student of classical and mediaeval literature, and indeed of literature generally. Although at first one is inclined to regard him as a compiler and nothing more, this impression is soon dissipated, and, from an incidental note in the second volume, one gathers that he is the possessor of a library of Galenic and other classical works on medicine. He writes as an enthusiastic student of the medical literature of ancient times; and expresses his regret that "Galen and the medical philosophers have been abandoned to a mere handful of research workers who are scattered from Leipzig and Vienna on one side to Washington on the other." He feels that an investigation of the individual manuscripts may yet reveal an aspect of the classics and mediaeval thought that up to the present is hidden. For this reason alone he has felt sufficiently enthusiastic to compile data of all the known Latin translations of Galen, which, together with the Latin translations from the Arabic, a short bibliography, and index, form the whole of the second volume.

The first volume opens with a chapter on Greek medicine and its relation to the Arabians, followed by a catalogue of the Arabian medical manuscripts and the libraries in which they are to be found. The author, however, does not tell us of any of these manuscripts being in the famous Karoun library of Fez. Access to it is difficult if not impossible for all except the followers of Islam, although it may be assumed to hold many treasures in the form of Arabian mediaeval documents and books. The works of Hippocrates, Aristotle, Galen, Paulus Aegineta, and others were preserved through the Dark Ages by Syriac translations, from which they were translated into Arabic by the Nestorians and formed the basis of the Arabic influence on mediaeval Europe. In extremely interesting and admirably written chapters Dr. Campbell traces the rise of Islamism and the influence of the physicians and surgeons of the Eastern and Western Caliphates on the culture of the Middle Ages. Many of them were Jews and some Christians—a fact which is evidence of the wide tolerance of the Moslems of that time. They followed the doctrines of Hippocrates and Galen, but the great writers, Rhazes and Avicenna in the East and Albucasis and Averroes in the West, had a more direct and personal influence on medical thought and education—an influence which continued for centuries after their time. Indeed, the establishment of universities and the regularization of medical practice owe their origin to the Arabism of the Middle Ages and to its influence on the intellectual currents of that period.

The reader is next carried in a most illuminating fashion through the transition stages of the transfer of European culture from Arabism to Hellenism during the Renaissance, and after the recovery of the original Greek texts from the libraries of Byzantium. Up till then the scholastics of Europe derived their knowledge of the Greek classics from imperfect Latin translations made from the Arabic; and the great controversy between Hellenism and Arabism arose when Latin translations were made direct from the Greek texts in the fifteenth and sixteenth centuries. Paracelsus, Copernicus, and Vesalius, all of whom were medical men, led the revolt against Arabism, and we are told that Paracelsus, in order to show his contempt for the Arabist school, publicly burnt the works of Galen and Avicenna, whose *Qānūn*, however, continued as a textbook in some of the European universities till the middle of the seven-

¹ *Arabian Medicine and its Influence on the Middle Ages*. In two volumes. By Dr. Donald Campbell. Trubner's Oriental Series. London: George Paul Trench, Trubner and Co., Ltd. 1926. (Extra post 8s.) Vol. I, pp. xv + 228, 2 maps; Vol. II, pp. 235. 21s. net the two volumes.)

teenth century. Arabic pharmacy survived to modern times, and Dr. Campbell remarks that in the nineteenth century we find "Lister with his modern system of treating wounds, as opposed to the salve-surgery of the Arabists, vociferously opposed by his contemporaries who still adhered to the methods commonly practised in mediæval times."

After reading these volumes we confess to an unbounded admiration for Dr. Campbell's literary skill and erudition. We feel sure more will be heard of him as author and scholar; and, unless we are mistaken, he has already shown literary versatility by the publication recently of a novel under a *nom de plume*.

POPULATION PROBLEMS.

PARTLY because of a similarity between our national position and that of our great-grandparents, interest in the manner of growth of population is much keener than at any time within the last fifty years. Both economists and statisticians of the first rank, such as Bonar, Keynes, Pearl, Yule, and Brownlee, have devoted attention to the subject and there has been the usual output of "theories." There was room, however, for an objective study of the growth of population at the beginning of the nineteenth century, and an assessment of the importance of the factors defined by Malthus and, rather uncritically, accepted or rejected by general historians. Mr. G. TALBOT GRIFFITH has provided such a study, in a book, *Population Problems of the Age of Malthus*,² which thoroughly repays perusal.

The task Mr. Griffith set himself was not an easy one. He had to face, not only all the ordinary difficulties of an historian but the special difficulties imposed by the fact that for the elucidation of a problem essentially statistical the data are extremely imperfect. It was not to be expected that a young writer would conquer all these difficulties. In places, Mr. Griffith perhaps seeks to deduce more than the data can fairly be made to yield. Sometimes—for instance, in his remarks on page 193 respecting phthisis—he betrays lack of acquaintance with relevant technical literature, and his narrative style has not the smoothness which comes by practice. These, however, are blemishes which experience is sure to remove, and we have seldom read a first book on a difficult subject which not only showed so much promise but actually achieved so much.

Although Mr. Griffith is not critical of Malthus in any hostile sense, the general trend of his argument is to show that Malthus overestimated the importance of various possible factors of population growth. In the first place, Mr. Griffith argues, we think correctly, that a decline of the death rate at the end of the eighteenth century and the beginning of the nineteenth went for much more in the increase of population than a rise in the birth rate, that diminished destruction rather than increased production was really at work. He then shows that, in all probability, the effect of the old law of settlement in checking, and of the Poor Law allowance system, inaugurated by the famous resolution of the Berkshire magistrates, in promoting, growth of population have been greatly exaggerated. Mr. Griffith's study of the effects of the allowance system is, we think, the most original and most important part of his book. By comparison of both actual growths and natural increases in counties affected much or little by the allowance system, together with a comparison of the rates of growth in England and Scotland, he makes it appear that both Malthus himself and the commissioners of 1834 much exaggerated the stimulus given to reckless propagation by the "Speenhamland Act." A study of the statistics of enclosures, if not equally convincing, at least shows that there is a doubt which may be the horse and which the cart.

In a chapter on the health of towns and factories, Mr. Griffith has collected a good deal of information, and concludes that although the difference between the death rate and the birth rate in towns was less than in the agricultural districts, it can hardly be said that town life was a serious check upon the growth of population. A chapter on

alcohol as a factor of mortality should be agreeable reading to the advocates of a dry England. Here, perhaps, not quite sufficient attention is directed to the probable unreliability of *per caput* consumption figures based upon official data, in the good old days of Smuggler Bill. But, with all reservations, the case against free trade in alcoholic liquors is obviously strong. The last chapter but one, dealing with the influence of our professional activities upon the death rate, is interesting. Of course, opinions must differ as to the emphasis which should be put upon this or that medical reform. On the whole, without any desire to depreciate Jenner, we believe that Mr. Griffith attributes too much to the beneficent influence of vaccination. Many first-rate authorities, however, would certainly agree with Mr. Griffith, and, so far as we can see, his sketch of medical history contains none of the "howlers" which a non-medical writer can so easily commit.

We think this a valuable book, congratulate the author on his achievement, and shall look forward with pleasurable anticipation to his next contribution to historical literature.

PUERPERAL SEPTICAEMIA AND INDUSTRIAL ACCIDENTS.

Dr. GEORGE GEDDES of Heywood has published in book form his monograph on *Puerperal Septicaemia*,² with which he won the Nicholls prize awarded by the Royal Society of Medicine in June, 1924, for the best essay upon this subject. This award of itself compels the serious attention of the profession to his observations. Many of our readers will recall his earlier work on the same subject—*Statistics of Puerperal Fever and Allied Infectious Diseases* published in 1912. The present volume is an elaboration of its predecessor, with a further collection of statistics which have confirmed the writer in the views he had reached as to the causation of puerperal infection.

Dr. Geddes practised in Scotland before he went to Heywood, and the occurrence of puerperal infection in his practice in the industrial area of Lancashire and its absence in his earlier experience led him to contrast the differences in the conditions of his two practices. After excluding many points in which the circumstances of both practices were alike, he came to the conclusion that the frequency of industrial accidents, followed by septic sores which he was called upon to treat, was the most important factor determining the incidence of puerperal infection. This led him to make a painstaking and most praiseworthy statistical investigation as to the relative frequency of puerperal infection and of industrial accidents in different districts of Lancashire. The results of his investigation have led him to formulate the view which is the theme of this volume, that "industrial accidents determine the puerperal fever rate in every district, because such accidents generally produce septic wounds. We assume for our purpose that "accident" and "septic wound" are synonymous terms, and a "unit" considered in their relationship to puerperal fever. The resulting septic wounds become sources of infection, and infect women in labour through the agency of medical practitioners, or other persons, but generally through medical practitioners, who cannot escape contamination by such wounds in the daily routine of industrial practice.

"I feel it necessary to reiterate the statement that the responsibility of the profession is accidental in a double sense, for accidents are incidental to their environment, and they become influenced thereby. One cannot handle pitch and remain undefiled. It is equally true that one cannot treat septic wounds without risk of being contaminated by septic germs... The cause of puerperal sepsis does not depend upon either the professional proficiency of the medical practitioners or the service of midwives, but upon the conditions under which they have to practise midwifery."

These extracts sum up in brief the author's thesis. His investigations point to the medical practitioner being more often the unconscious agent of infection than the midwife, who is not called upon to handle septic wounds. Dr. Geddes very properly absolves the profession from blame in this matter, although not from responsibility, because,

² *Population Problems of the Age of Malthus*. By G. Talbot Griffith, B.A. Cambridge: The University Press. 1925. (Demy 8vo, pp. 276; 4 diagrams. 12s. 6d. net.)

² *Puerperal Septicaemia*. By George Geddes, M.D., C.M.Aber. Bristol: John Wright and Sons, Ltd.; London: Simpkin, Marshall, Hamilton, Kent and Co., Ltd. 1925. (Demy 8vo, pp. vi + 20; 18 figures. 12s. 6d. net.)

as he points out, the conditions in which the general practitioner is compelled to work make the conveyance of infection almost unavoidable. The author, of course, recognizes other possible sources of infection, particularly the carrying of germs from one infected case to another, but he comes back to his main point, that *the factor* which determines the incidence of puerperal fever in every district is the incidence of septic wounds caused by industrial accidents.

Dr. Geddes supports his thesis with a vast number of most carefully compiled statistics, dealing with different areas and with different industrial groups—for example, residential districts, rural districts, weaving districts, spinning districts, mining districts, engineering districts, and so on. He claims further—a most interesting point—that cessation of work in mining districts during the various coal strikes produced effects upon the puerperal sepsis rate which serve to control and confirm his thesis. It is not easy for the ordinary individual, to whom statistics are more or less of a mathematical puzzle, to assess the absolute accuracy of his deductions. He certainly seems to make out a fair case. This volume contains merely a synopsis of the more important of the large number of tables which he submitted for the Nicholls prize, and he states that a member of the committee which awarded the prize suggested that he might submit the statistical portion to Mr. Caradog Jones, lecturer in social statistics at Liverpool University. He acted upon this advice, and Mr. Caradog Jones worked out the coefficients of correlation of certain factors, with the following results:

Correlation between puerperal fever rate per 1,000 births and—

- (1) Accident rate per 1,000 population = 0.216 ± 0.058 (mining districts included);
- (2) Accident rate per 1,000 population = 0.110 ± 0.067 (mining districts excluded);
- (3) Accident rate per 50 "M. and D." births = 0.213 ± 0.058 (mining districts included);
- (4) Accident rate per 50 "M. and D." births = 0.160 ± 0.066 (mining districts excluded);
- (5) Erysipelas rate per 1,000 population = 0.217 ± 0.065 (mining districts excluded).

He (Mr. Caradog Jones) says: "The results indicate a small positive correlation between the puerperal fever rate and the accident rate, and between the puerperal fever rate and the erysipelas rate, but in view of the size of the probable errors, it is not certain that the results obtained are significant."

With regard to the general matter of Dr. Geddes's thesis, it would be easy enough, but not very generous, to pick holes here and there. We feel compelled, however, to draw attention to the scepticism which he evinces with regard to the possibility of a patient becoming infected in the puerperium from pre-existing infected conditions in her own body. Sufficient cases of this sort have been recorded by high authorities to make it clear that this is at any rate a possible cause of puerperal infection, and it is difficult to understand how or why Dr. Geddes should remain sceptical. The mere fact which he quotes as an argument against this, that he attended a patient suffering from cystitis who had no rise of temperature in the puerperium, is neither here nor there, and arguments of this sort, based upon one or two individual cases, can carry no weight.

A point upon which we would join issue with Dr. Geddes is in the scant courtesy with which he treats the report of the Departmental Committee on Puerperal Morbidity and Mortality appointed by the Scottish Board of Health, which came under his notice on the day when his thesis was about to leave his hands for the bookbinder. It would have been wiser had he either taken more time to study this report, or else have avoided reference to it altogether, for it is not accurate to say that "it throws no light on the problem of causation, and therefore its suggestions for prevention are useless. Those who drew up this report are, if I may say so, under the same disability that I was before I left Scotland, and lack the personal experience which has opened my eyes to the problem." And it is literally scant courtesy to stigmatize the conclusions of this committee as "futile."

"M. and D." births we mean births where doctors are present alone, and those where they are present with midwives."

One other disappointing feature of Dr. Geddes's book is that it does not appear to recognize the enormous importance in this connexion, as well as in relation to other causes of puerperal morbidity and mortality, of adequate ante-natal supervision.

The author's recommendations as to prevention follow naturally from the conclusions he has reached with regard to the conditions determining the incidence of the disease.

"The only way to prevent puerperal septicaemia is to prevent those most in contact with septic wounds from attending puerperal women. Who are they? I answer unhesitatingly, 'general medical practitioners,' especially those practising in industrial districts. If this be an impracticable gospel—and one must admit that it is—then the only alternative is that all labours should be conducted under strictly aseptic conditions; such conditions are only possible in lying-in institutions."

In addition to this recommendation, the author refers to the strengthening of the patient's resistance against the infecting organisms, and the ante-natal attention to vaginal discharges and other signs or symptoms of infection. He recommends the wearing of rubber gloves, but makes the unfortunate and dangerously misleading statement that "if these are to be worn, there need not be the same care bestowed upon the hands." It is just here that rubber gloves are apt to be a trap and possibly more dangerous than the bare hand, for there is no surgical procedure in which gloves are so apt to be damaged as in a midwifery case. The author's other recommendations need not be specified. They are, like those which have already been referred to, closely in line with the recommendations which have been made from time to time by individual obstetricians and the various committees. Indeed, some of them are in substance very like the "futile" recommendations of the Scottish Departmental Committee.

These criticisms apart, Dr. Geddes's work will stand as a suggestive and interesting contribution to this most baffling subject, and we congratulate him upon the perseverance and assiduity with which he has conducted a laborious and painstaking research, while engaged in the harassing work of a large general practice. The circumstances in which the book was written explain in large measure such weaknesses as are present in his thesis, and the comparative paucity of references to the researches of others in the same field.

NOTES ON BOOKS.

AN author who styles himself JAMES BRIDIE, a "quiet, respectable practitioner of medicine," has written an account, under the title *Some Talk of Alexander*, of what happened to him during the years 1917-19. The spirit of adventure which led him to France early in the war was dead by the time he took ship for the East; but the Arabian nights and days through which he passed left upon him an impression which has induced him to write this book of quaint disconnected incidents. A comic chart of the itinerary contrived after the fashion of seventeenth century maps is prefixed to the volume; and interludes, intended to be metrical but hardly poetic, separate the chapters. So we wander pleasantly from India to Mesopotamia and Northern Persia, through Kasvin to Baku. In each country we learn much of the manners and habits of the natives from the amusing incidents described by James Bridie. In the chapter entitled "The Pax Britannica" it is inspiring to read of British prestige in Baku and South Russia in 1919, illustrated by the story of "How the Quartermaster Stopped the War" between Armenia and Georgia. *Some Talk of Alexander* is an entertaining book, for which the author's apologies in his preface are unnecessary.

"*Train Up a Child . . .*" is an interesting and comprehensive book on the upbringing and education of children, a subject which has presented its problems in all countries and in all ages. Judged by the evidence which Dr. McVittie produces, some countries have solved their problems with far greater wisdom and foresight than we in Great Britain have yet shown. His book deals with the physical, mental, and spiritual development of the individual, and contains many historical allusions, though the problems of the present:

"*Some Talk of Alexander*. By James Bridie. London: Methuen and Co., Ltd. 1925. (Cr. 8vo, pp. xii + 180. 6s. net.)

"*Train Up a Child . . .*" By Robert Blake McVittie, M.D. London: John Murray. 1925. (Cr. 8vo, pp. xvi + 272; 64 figures. 7s. 6d. net.)

day are those chiefly considered. The first three chapters are devoted to pre-natal existence. In the first chapter certain remarks on the diurnal tide of energy are made, as indicating the reason for the midday meal and the necessity for rest at this time. The author has collected information from many sources and has had practical demonstration of the training of children in various countries. Italian, Dutch, Swiss, and especially Swedish methods, are discussed. Much space is devoted to the Swedish Sjöjd system, of which the author thinks very highly. Its graduated exercises in paper, wood, metal, drawing, singing, gymnastics, and games encourages the full development of the senses and freedom of movement of the body. The author claims that "the educational value of an idea is its capacity for association and suggestion." Failure to interest the child means failure to educate him. The choice and training of teachers, the construction of schools, the composition of boards of management, are all considered from the point of view of benefit to the child, and ultimately to the nation. The author's conclusions should stimulate to further efforts all who are interested in children. His hope is to direct attention "to the paramount importance of accepting the child as a physiological creature." Dr. McVittie's conception of the aim of education and his criticism of existing methods appear in the following extracts: "The aim of true education should be more abundant life, physically, mentally, morally, and spiritually," but the prevailing system frequently results in "more abundant crooked spines, contracted chests, dilated hearts, stomachs and bowels, twisted limbs, damaged eyes, exhausted nervous systems, irritability of temper, and unreliability of character."

THE ROYAL MEDICAL BENEVOLENT FUND.

The annual meeting of the Royal Medical Benevolent Fund took place on April 20th, with the President, Sir THOMAS BARLOW, Bt., in the chair.

The financial statement, as presented by Sir CHARTERS SYMONDS, the honorary treasurer, showed that the book value of the invested property of the Fund stood at £103,887, and the treasurer said that the present market value was only slightly lower. The subscriptions and donations during the year amounted to £6,685, as against £4,780 in 1924. The amount expended in grants was £5,371, and in payments to annuitants and Christmas gifts, £3,850. The total expenditure was £10,549, of which £1,308 represented working expenses. Legacies had been received (including one of the nominal value of £3,325 under the will of the late Dr. M. G. Evans) to the amount of £4,300, and in addition there was a contingent legacy of £5,000 under the will of the late Sir Rickman Godlee.

Dr. NEWTON PITT, in his report as honorary secretary, said that the Fund had gratefully to acknowledge a special donation of £1,000 from Dr. W. Tinker, also a grant of five hundred guineas from the Medical Insurance Agency, together with a contribution of fifty guineas from the same source to the Christmas gifts. Another interesting donation was from a practitioner who sent a sum equal to two guineas for every year in which he had been in practice, accompanying it with the remark that his conscience troubled him because he had not supported the Fund earlier.

The number of persons relieved during the year was 392 by grants and 167 by annuities. The demands on the grants department had increased very considerably, and he was sure that if the distressing nature of many of the cases was more widely known there would be a still more generous response in the way of subscriptions and donations. During the year eleven annuitants had died, and the committee had elected 39 annuitants and had increased the annuities in 17 cases. The Fund was able to grant 20 annuities of £40, 19 of £30, 30 of £26, and 64 of about £20. Under the war emergency fund, now coming to an end, £1,778 had been distributed during the year, the greater part for the education of 29 children, and the remainder in the shape of grants to six medical officers.

The committee desired to tender its thanks to the British Medical Association for its assistance in collecting subscriptions amounting to £1,090 during the year, an increase of £79 on the amount so collected for the year preceding. The Fund had also co-operated with the Medical Secretaries of the Association in several cases requiring investigation and assistance. Attention was drawn to the good work of

the local honorary secretaries of the Fund, who, particularly in Scotland, Lancashire, and Devon, had been instrumental in collecting large amounts.

Sir THOMAS BARLOW, speaking from the chair, paid a tribute to the Ladies' Guild, which, he said, brought into the work a personal touch and sympathy which was most valuable. He also emphasized the fact that the Fund did not in the least do away with the need for local help. The Fund throughout had a supplementary function. He spoke of the painful nature of many of the cases, not least those in which, along with dire need, there was evidence of thriftlessness and lack of adaptability to changed circumstances.

Sir Thomas Barlow was re-elected president of the Fund, and to the list of vice-presidents, already numbering close upon one hundred, ten further names were added. From the Committee of Management it was reported that Sir HUMPHRY ROLLESTON and Dr. ARNOLD CHAPLIN had resigned, the former owing to his work at Cambridge, and the annual meeting elected to the committee five new members—namely, Sir JOHN BROADBENT, Dr. G. de BEC TURTLE, Mr. H. M. STRATFORD, Mr. F. A. JULER, and Mr. W. GIRLING BALL. Sir CHARTERS SYMONDS was re-elected treasurer, and Dr. NEWTON PITT and Mr. R. M. HANDFIELD-JONES joint honorary secretaries. Votes of thanks were accorded to the president, officers, and committee, and, on the motion of Dr. NEWTON PITT, to the medical and lay press. Dr. PITT said that, in addition to publishing monthly reports of cases, the BRITISH MEDICAL JOURNAL had published an appeal for Christmas gifts which had brought in a very favourable response. The special efforts of the British Medical Association to benefit the charity were much appreciated.

BRITISH EMPIRE CANCER CAMPAIGN.

GRANTS FOR RESEARCH.

At the quarterly meeting of the Grand Council of the British Empire Cancer Campaign, held on April 13th at the offices of the British Red Cross Society, 19, Berkeley Street, London, W., a number of grants to hospitals and individual workers were made. In the absence of Viscount CAVE, Sir JOHN BLAND-SUTTON, Bt., President of the Royal College of Surgeons of England, took the chair.

Lieut.-General Sir JOHN GOODWIN, K.C.B., organizing adviser to the Campaign, reported satisfactory progress in the scheme of local organization by county committees. Excellent headway had been made by the Yorkshire appeal for funds to establish a Yorkshire cancer research centre, and by the Birmingham appeal for setting up a similar centre in that city. Strong county committees had been organized in Kent, Essex, Hertfordshire, and the Isle of Wight, while the Lord-Lieutenants or other important county officials of Sussex, Surrey, Bedfordshire, Durham, Norfolk, Hampshire, and Berkshire had signified their willingness to appoint county committees in support of the Campaign.

The following grants were made: £1,695 to St. Bartholomew's Hospital, towards the maintenance of the new X-Ray Cancer Research Department; £2,500 to the Cancer Hospital, towards the upkeep of the Research Institute; £3,000 to the Middlesex Hospital, for cancer research; £300 to Dr. Malcolm Donaldson (St. Bartholomew's Hospital), in connexion with his investigations into inoperable cancer of the cervix uteri; a further £250 to St. Mark's Hospital, for cancer research, making a total grant of £500 for the year; £300 to Dr. Charles Walker (Liverpool University), to defray certain cancer research expenses; and £300 to Professor D. P. D. WILKIE (Edinburgh University), for the purchase of apparatus and material for use in cancer research. These grants, together with sums set aside for commitments entered into by the Campaign, amount to an expenditure of approximately £85,000 to date.

It was reported that the first number of the new publication, to be known as the *Cancer Review*, would be issued in May, under the editorship of Dr. Francis Cavers, and would continue thereafter as a monthly publication. It would embrace reports of all cancer research work being undertaken throughout the world, and it was hoped that in this and other ways the new periodical would link up the work of all cancer researchers. Mr. J. P. LOCKHART-MUMMERY, F.R.C.S., chairman of the executive committee, again undertook to edit the annual report of the work of the Campaign. Professor R. T. LEIPER, M.D., D.Sc., F.R.S., of the London School of Hygiene and Tropical Medicine, was elected a member of the Grand Council.

REPORT OF THE DEPARTMENTAL COMMITTEE
ON MULE-SPINNER'S CANCER.

THE condition now generally known as mule-spinner's cancer was practically unheard of until 1922, when it was brought into prominence in a paper by Mr. A. H. Southam and Mr. S. R. Wilson, published in the *BRITISH MEDICAL JOURNAL* of November 18th, 1922 (p. 971). In this paper attention was drawn to the prevalence of epithelioma of the scrotum among spinners in South Lancashire, and the suggestion was put forward that the disease was due to soiling of the clothes by the lubricating oil used on the spinning machinery. The article was illustrated by photographs showing the characteristic attitude adopted by the spinner when at work to explain the incidence of the disease on the scrotum.

As a result of the widespread interest aroused by the paper, and the alarm it caused amongst workers in the cotton trade, the Home Secretary appointed a departmental committee in March, 1925, to consider evidence at present available as to the occurrence of this condition, and "to report what measures are practicable for the protection of the workers, and what regulations (if any) are required." This report* has now been issued, and it is interesting to find that it practically confirms the suggestions originally brought forward in 1922 by Southam and Wilson. Since the 69 original cases recorded in their article the committee has been able to trace up to the present 539 cases. But it is remarked that many other cases must have escaped notice.

The following table shows the geographical distribution of the cases which have actually been brought to the notice of the committee, collected from 1876 onwards.

TABLE I.—Geographical Distribution of Cases Collected from 1876 onwards.

District.*	Spinners.		Ex-spinners† in other Occupations.		Total.
	Scrotum.	Other Parts of the Skin.	Scrotum.	Other Parts of the Skin.	
Oldham (5,121) ...	160	39	25	4	229
Bolton (3,200) ...	57	12	11	—	80
Ash-ton-under-Lyne (1,740) ...	25	8	11	2	46

Stockport (755) ...	7	1	4	—	12
Halifax (625) ...	5	2	1	—	8
Manchester (514) ...	11	2	2	1	16
Barnley (427) ...	18	2	2	—	22
Huddersfield (329) ...	4	—	—	—	4
Keighley (55) ...	1	—	—	—	1
Total (32,699) ...	331	79	69	10	539

* The districts include not only the towns mentioned but also the adjacent areas, and the figures in italics after each town show the number of spinners, excluding piecers, employed in these areas in 1925.

† The only cases included in these columns are those of persons whose leading occupation has been that of spinning.

Inquiry abroad as to evidence of a similar incidence amongst mule-spinners in France, Germany, Russia, Poland, and America has led to entirely negative results.

The report shows that with the exception of patent-fuel workers and chimney-sweeps, the mean annual death rate for persons employed in cotton-spinning processes is very

* Report of the Departmental Committee (Home Office) appointed to consider Evidence as to the Occurrence of Epitheliomatous Ulceration among Mule-Spinners, 1926. H.M. Stationery Office (London, Manchester, Cardiff, Edinburgh, Belfast), or through any bookseller. Price 1s. net.

much higher than that for any other class of worker. Another table shows that the mortality among cotton-spinners is fourteen times as great at the ages of 25 to 35 as that in the general population, between the ages of 45 to 55 it is sixty times as great, and between 55 and 75 a hundred times as great. Inquiries, moreover, go to show that the incidence of the condition has been rapidly increasing. Returns prove that the number of deaths from it has increased at a rate out of all proportion to the increase of spinners employed.

The earliest age at which the condition was recognized was 22 years, and the latest 77 years. The age period at which it appears to be specially liable to manifest itself commences at 35 years, and reaches its maximum at about 55, the average age for all cases being 52.4 years.

While the majority of cases occur on the scrotum, the growths may be found on other parts of the body. In 539 cases the disease was on the scrotum in 450 (83.5 per cent.) and on other parts of the skin in 89 (16.5 per cent.). The following table shows the different parts of the body on which the growths were found.

TABLE II.—Site of Disease.

Site.	Spinners.	Ex-spinners in other Occupations.	Total.
1.	2.	3.	4.
Scrotum	381	69	450
Head and neck	29	2	31
Upper limb	22	1	23
Lower limb	13	1	14
Groin and trunk	5	1	6
Penis	10	3	13
Multiple—			
Leg and arm	1	—	1
Forearm and ear	—	1	1
Ear and scrotum	—	1	1
Penis and scrotum	2	—	2
Total	460	79	539

While, therefore, the scrotum is undoubtedly the site of election, these figures suggest that approximately 25 per cent. occur in other parts of the body.

It appears that wart formation usually precedes, sometimes by many years, the development of the cancer. The warts may be single or several may develop at one time. Once it has started as an epithelioma the progress of the growth is rapid, and as the months pass the prospect of effective cure is diminished. Medical evidence is to the effect that if the wart is removed early there is a good chance of a permanent cure. The scrotal growth soon spreads to the glands, but in other situations the progress of the disease appears to be relatively slow and more amenable to treatment.

In dealing with the cause of the disease, the report recalls that Southam and Wilson put forward the suggestion that in these operations the substance responsible for causing the disease was the mineral oil used in lubricating the spindles. They based their view on the knowledge that in other forms of cancer tar and paraffin were recognized as direct causal agents and were shown by animal experiments to have such a property. The proof that certain mineral oils are capable of inducing cancer of the skin is twofold, being founded on observations on men and experiments on animals. Scott has provided evidence of the occurrence of epithelioma amongst the employees in the Scottish shale industry, whilst experimental evidence has been furnished by Leitch with his experiments on mice.

The report then goes on to state:

"We have thus conclusive evidence that certain mineral oils, including such refined mixtures as lubricating oil, are capable of inducing epitheliomatous formation when the subject has long been exposed to their action. Whether these oils are the direct immediate products of the cancerous growth, or merely the

principal factors that prepare the soil for some other and more general cancer-producing agent, is a scientific matter, which we are not called upon to settle. The broad fact is beyond reasonable dispute, namely, that in the absence of exposure to such mineral oils there would be no mule-spinner's cancer. It does not follow that all mineral oils necessarily have this effect; some, indeed, may be found on investigation to be innocuous; but until any particular oil is shown to be free from cancer-producing property, it must be regarded as dangerous. In this connexion it should be mentioned that our attention has been called to a certain oil which was claimed to be harmless. It was said to have been prepared after careful chemical analysis, and there is no doubt that the producers felt satisfied that the dangerous elements had been eliminated; but we feel it necessary to point out that their opinion was based on a purely chemical test, and that the oil has not been subjected to any physiological test. We think that in the absence of such physiological proof the oil cannot be regarded as free from danger."

The construction and working of the mule is given, and it is shown how oil is thrown off the spindles, sometimes at the rate of one-thirteenth of a pint a day per mule of 1,320 spindles. This test was carried out at random and the conditions were not abnormal. Fine particles of oil are also to be found continually in suspension in the air of the room, whilst it is not unusual to find oil on the trousers from contact with the carriage doors.

Other factors may be present, but none of them has been shown to have any direct bearing on the causation of the disease. The committee comes to the conclusion that the evidence is strongly in favour of this disease being due to the prolonged action of mineral oils.

The committee, having reached these conclusions, has had to consider what means can best be adopted to combat the disease, and the following recommendations are set out.

Summary of Recommendations.

(1) Institution of experimental research into oils with a view to finding oils which are innocuous and at the same time suitable as lubricants.

(2) Development of a non-splash type of spindle bearing, more particularly for new mules.

(3) Prevention of oil splash from the spindles of existing mules by means of some form of guard, the type to be decided by a series of tests to be mutually agreed upon and arranged by the Masters' Federation and the operative spinners.

(4) Periodic medical examination of the workers.

(a) To be tried at first on a voluntary basis, but, if unsuccessful in one year or at any subsequent period, to be made compulsory.

(b) To be performed at the factory.

(c) To take place at least every four months.

(d) To include every worker in the mule-spinning room who is 30 years of age and over.

(e) To be performed by three or four medical men appointed by the trade, with Home Office approval, for the whole area, or failing this by special medical men appointed for suitable areas by the Home Office in conjunction with trade representatives, all workers in any given area to be examined by one man.

(5) Education by periodic distribution of leaflets in order to direct attention to the importance of cleanliness and to the danger of delay in securing early treatment.

The committee concludes its report by paying a tribute to its secretary, Dr. S. A. Henry of Manchester, medical inspector of factories, who has followed up cases of the disease and has made a careful search through the records extending over many years in Lancashire hospitals and through death registers, which has thrown an important light on the dates from which this disease began to manifest itself and of the increase in its incidence during recent years.

RADIUM THERAPY.

REPORTS FROM RESEARCH CENTRES.

The Medical Research Council has published a summary of reports for 1924 from the various centres where investigations are being made into the medical use of radium supplied by the Council. In the *JOURNAL* of December 20th, 1924 (p. 1170), we dealt at length with a previous similar report for 1923, describing the way in which this research had originated at the end of the war and was being conducted. In the present report¹ it is announced that the original general scheme is now being extended in two main

directions. Further quantities of radium salt have been made available by the British Empire Cancer Campaign and a campaign in connexion with St. Bartholomew's Hospital; fresh allocations of radium were also made to St. Peter's Hospital, London, and to a committee of the London Association of the Medical Women's Federation for use in a group of hospitals. In the second place, arrangements have been made to augment the resources of the different clinical centres participating in the scheme by the establishment of a depot at the Middlesex Hospital for a supply of radium emanation (radon), under the supervision of Professor Sidney Russ, D.Sc., the expenses being defrayed by the British Empire Cancer Campaign. An account of these arrangements for the supply of radium emanation is given in an appendix to the report and is illustrated by photographs of apparatus.

In discussing the previous report we mentioned that an arrangement had been made by which the Radiology Committee originally appointed by the Medical Research Council should also co-operate in this campaign, and this committee has drawn up working conditions as follows. Radon will be supplied to any applicant associated with the radium investigations of the Medical Research Council, one week's supply being the maximum quantity issued. Priority is given to applications where the radon is required in a form in which the solid salt cannot be used. Requests for radon for biological or physical research will be met wherever possible. During eight months there were 129 requisitions for radon, the number of millicuries used being about 3,600. Nine clinical centres are concerned in this work: they are the Middlesex Hospital, University College Hospital, St. Bartholomew's Hospital, King's College Hospital, the London Hospital, the Birmingham General Hospital, Cardiff Royal Infirmary, Aberdeen Royal Infirmary, and the Irish Public Health Council in Dublin. The salt allocated to the last named centre has been used as a source of emanation for distribution in Ireland. Fractions of radium salt have also been allocated for purely experimental work to Dr. J. C. Mottram of the Radium Institute, and Sir Ernest Rutherford at the Cavendish Laboratory, Cambridge; a small quantity has also been lent to Mr. A. G. T. Fisher for work upon arthritis. At several of the clinical centres the radium is also available for experimental work.

Clinical Investigations.

The present summary of the reports from the different centres upon the work of 1924 deals with three main subjects—namely, clinical investigations in malignant disease and in non-malignant conditions, and experimental investigations. The malignant diseases are divided into five sections according to the site and nature of the malignant growth. Non-malignant conditions are dealt with in a separate section.

1. Cancer of the breast has been treated at the Middlesex Hospital by surgical and by surface radium therapy, and at St. Bartholomew's Hospital by surgical radium therapy. The conclusions drawn are that radium has a definite therapeutic value in breast cancer; local recurrences treated by the surgical insertion of radium are often checked, and may sometimes disappear after the use of comparatively large doses. More information is still required in order to define the optimum intervals of time and the doses of radiation in the surface therapy of inoperable tumours.

2. Cancer of the uterus was dealt with by seven centres. The report of University College Hospital contains an analysis of twenty cases of carcinoma of the cervix treated during the previous twelve months, and a short summary of seventy-eight cases treated from May, 1921, to October, 1924, including two cases of carcinoma of the body of the uterus, one of vaginal carcinoma, and one of vulval carcinoma. St. Bartholomew's Hospital supplies an abstract of the work during the three and a half years ending May, 1924. A synopsis is given of eighty-five cases of carcinoma treated with radium only, and sections are devoted to discussions of the value of radium as a palliative, curative, and prophylactic agent, and to dosage. Cardiff Royal Infirmary reports on the treatment of forty cases of cervical carcinoma, six of carcinoma of the body of the uterus, one of uterine sarcoma, two of carcinoma of the vagina, and three of vulval carcinoma. The London Hospital dealt with twenty-one cases of inoperable carcinoma of the cervix, eleven of cervical cancer followed by Wertheim's hysterectomy, and four cases of cervical cancer followed by panhysterectomy. At Aberdeen Royal Infirmary six cases of cancer of the cervix and one of the

COMMITTEE ON VACCINATION.

vulva were treated. Birmingham General Hospital used the radium for fifteen inoperable cases of cervical carcinoma, and one of epithelioma of the vulva. King's College Hospital treated twenty cases of carcinoma of the cervix, mostly inoperable, and the Irish Public Health Council dealt with a smaller number of cases of cervical cancer and cancer of the body and vulva. The conclusions drawn from the combined results in these reports are that radium treatment is of the greatest value as a palliative for malignant diseases of the uterus. Haemorrhage ceased in nearly all the cases, the local growth disappeared in the great majority, the patients improved in health and gained weight, and in many instances life was definitely prolonged. Histological examination proved that where the growth was localized in the cervix the malignant cells were completely destroyed in certain cases. Although the evidence is insufficient to indicate which is the best technique, it appears that the majority of failures are due to insufficient treatment received by the periphery of the growth—that is, in the parametric tissues and metastases in the glands. It was shown that tissues two inches away from the radium source only received about one thousandth part of the dose obtained by the tissues in contact with the radium. The Radiology Committee is convinced that the probable limits of uterine malignant growth cannot be efficiently treated by placing a single tube of radium in the cervical canal. Some evidence was forthcoming that a small dose given over a long period was very efficacious, but in the majority of cases where a small dose was used for a long time the radium was also distributed more evenly through the tumour than was possible using few foci of radiation. It appeared also that when hysterectomy was performed soon after the application of radium no great difficulties had been added to the operation by this preliminary treatment.

3. Cancers of the mouth, naso-pharynx, larynx, and oesophagus were treated at the Middlesex Hospital (thirteen cases), St. Bartholomew's Hospital (twenty-nine cases), University College Hospital (eight cases), and Aberdeen Royal Infirmary (five cases). Birmingham General Hospital reported that the treatment of oesophageal cancer by radium alone had been abandoned, but that radium was still employed in conjunction with diathermy. The conclusions drawn from the results in these reports are that the value of radium therapy in malignancy in these neighbourhoods is very dependent on the technique adopted, and that owing to the great variety of the involvement in malignancy no sharp determination of the factors with dosage can be expected. Secondary growths in these sites may disappear under irradiation, without the process of dissemination from the primary growth elsewhere being stopped. Sepsis was one of the most important factors limiting the establishment of a satisfactory technique. The irradiation of tumours with numerous, though weak, radium sources, applied for a long time, appeared hopeful, but more cases were needed before definite conclusions could be reached.

4. The number of sarcoma and lymphosarcoma cases treated was sixty-six, the clinical centres concerned being the Middlesex Hospital, University College Hospital, the Royal Infirmary, Aberdeen, the Cardiff Royal Infirmary, King's College Hospital, and the Irish Public Health Council. An attempt is being made to correlate the clinical results of treatment with the histological features of the growths.

5. Rodent ulcers were treated at the Middlesex Hospital (forty-nine cases), King's College Hospital (twenty-seven cases), Birmingham General Hospital (forty cases), Cardiff Royal Infirmary (two cases). It was found that radium therapy was effective in a large proportion of rodent ulcers, but that there was a tendency for recurrence of the growths. Recurrence was a tendency of the growth indicated unusual resistance of the surface of irradiation, but when it occurred in cells at these cells to irradiation, but when it occurred in cells at considerable depth below the surface it pointed to a probable defect of the beta-ray application—namely, insufficient intensity at comparatively small depths. Since the probability of such recurrence is much diminished by the use of gamma-ray sources, it is suggested that it would be useful to have information about the end-results of treatment of such rodent growths by means of gamma-ray sources of known intensity.

6. The non-malignant gynaecological conditions dealt with consisted mainly of menorrhagia and irregular uterine haemorrhage, especially at the menopause, and of fibroids giving rise to menorrhagia. The Committee expresses itself as convinced that radium is completely efficient in creating an artificial menopause, or in cutting short a prolonged and abnormal menopause. The minimum dose for this result would appear to be about 35 mg. of radium element used for twenty-four hours, but the usual dose is 70 mg., retained in the body of the uterus for twenty-four hours; this is more certain in its results. It is noted that at University College Hospital radium is used as a routine treatment in such cases, and the Committee concludes that more research work might profitably be carried on in patients aged between 25 and 40, suffering

from intractable haemorrhage, and in whom it is desired to control the haemorrhage by small doses without causing a premature menopause. Radium treatment was found very valuable in the case of small fibroids giving rise to menorrhagia, but generally caused an artificial menopause; in a few cases the fibroids diminished in size. It is suggested that more attention might be devoted to patients suffering from chronic cervicitis, with a view to discovering whether it is possible to destroy the mucous glands of the cervix without destroying the ovaries and producing an artificial climacteric. Two cases of myeloid leukaemia were treated at the Middlesex Hospital, and Aberdeen Royal Infirmary dealt with five cases of this disease, one of polycythaemia, and two cases of Hodgkin's disease. In six of the seven cases of myeloid leukaemia treated by the external application of radium to the spleen or to the long bones considerable improvement followed; in some cases a quick and pronounced fall in the numbers of circulating leucocytes occurred. The detailed blood counts in the seven cases of myeloid leukaemia are reproduced in full.

Experimental Investigations.

With regard to the experimental investigations, it is stated that Sir Ernest Rutherford is continuing his work at the Cavendish Laboratory on the subject of atomic constitution and stability, greatly helped by the loan of radium. Dr. H. A. Colwell is investigating the effectiveness of secondary radiations, when such radiations are generated in the intima of living structures. Professor E. C. Dodds and Dr. D. Webster have continued their study of metabolic changes associated with α rays and radium treatment. Dr. J. C. Mottram, at the Radium Institute, has published an investigation into the skin reactions of exposure to radium as affected by heat and cold; other lines of research are also being followed. The work of the different clinical centres is directed by local research committees.

COMMITTEE ON VACCINATION
(MINISTRY OF HEALTH).

REQUEST TO MEDICAL PRACTITIONERS.

The Departmental Committee on Vaccination recently appointed by the Minister of Health considers it desirable to invite the assistance of all members of the medical profession who are in active practice in this country in the elucidation of a question which has arisen under its official reference.

The Committee has decided to make a special study during the next twelve months of all cases in which the occurrence of acute disease of the central nervous system (such as meningitis of any kind or origin, encephalitis, poliomyelitis) has been "post-vaccinal"—using this term in the sense that the first symptoms have occurred within four weeks of vaccination.

The object of the Committee is to obtain a collection of data sufficient to enable it to ascertain whether there are any features which distinguish cases of acute nervous disease which happen to be "post-vaccinal" (as defined above) from those which are not.

The request which is, therefore, made to all practising members of the medical profession is that, when called in to any case of disease of the central nervous system with an acute onset, they will be so good as to inform the Committee as soon as possible of every case in which they have ascertained that vaccination has preceded the onset of the symptoms within a period of four weeks. The intimation should be sent as speedily as possible to the Secretary of the Departmental Committee on Vaccination (Dr. J. R. Hutchinson), Ministry of Health, Whitehall, London, S.W.1. The appointment and constitution of the Committee were recorded in the *BRITISH MEDICAL JOURNAL* of February 13th, 1926 (p. 294).

British Medical Journal.

SATURDAY, APRIL 24TH, 1926.

ENDOCARDITIS.

IT is forty-one years since Sir William Osler gave the Goulstonian Lectures on malignant endocarditis before the Royal College of Physicians of London, and twenty-three years since the veteran Professor T. R. Glynn's Lumleian Lectures on infective endocarditis; it is seventeen years since Sir Norman Moore delivered the same course on rheumatic fever and valvular disease, and now his distinguished pupil, Sir Thomas Horder, has reviewed the whole subject of endocarditis in the Lumleian Lectures for this year, the text of which has been published in our columns during recent weeks, the last in this issue (p. 733). The time for such a general survey of the subject is ripe, but the field is very extensive, as is shown by the following among other considerations: the probable but not accepted infective origin of rheumatic fever, the investigations of Libman and Baehr in America, of Lewis and Grant, Cotton and Starling in this country on bacterial endocarditis, which has bulked so much more since the war, Poynton and Carey Coombs's work, W. S. Thayer's elaborate analysis¹ of the 362 cases of acute and subacute endocarditis studied during thirty-four and a half years (1890-1923 inclusive) at the Johns Hopkins Hospital, and the campaigns to prevent rheumatic heart disease. It should also be recalled that Sir Thomas Horder in 1909 analysed 150 cases of infective endocarditis especially with reference to the chronic form of the disease, and that his paper appeared in the same volume of the *Quarterly Journal of Medicine* as one by Sir William Osler on chronic infectious endocarditis.

Starting with the conditions of rheumatic carditis and syphilitic disease of the heart and aorta, Sir Thomas Horder pays a tribute to Sturges's forty-two-years-old conception of rheumatic carditis, now histologically established by Aschoff's perivascular bodies, the existence of which was early and independently confirmed in this country by Dr. Carey Coombs. The Lumleian lecturer, however, is careful to express his opinion that failure to find Aschoff's nodes in an old cardiac lesion does not exclude its rheumatic origin. Professor Thayer regards them as quite specific of acute rheumatic pancarditis and unlike anything else; but Sir Thomas Horder, from a cautious comparison with military syphilomas, expresses mild surprise that the possibility of a spirochaetal origin for acute rheumatism has not attracted attention. A reference to Sir William Church's analysis of 700 cases of rheumatic fever in 1887 raises the interesting question of the change that has taken place in the clinical characters of the disease since Peter Mere Latham's classical lectures describing its acute and stormy features before 1840, and the lecturer suggests that the exudative lesions, such as pericarditis, have become less common and the proliferative perhaps more frequent. Though no statistics are given, belief in the increased incidence of subacute and chronic rheumatic endocarditis is in accordance with general opinion. The much discussed problem of the distinction of rheumatic from other established forms of cardiac infection

is dealt with by Professor Thayer, among whose 362 cases of endocarditis there appeared to be 43 cases of acute rheumatic endocarditis; but these were cut down to 24 by the rigid application of his criteria of rheumatic heart disease—namely, a rheumatic history, a negative bacteriological result from blood cultures during life, and from the blood and cardiac lesions after death. In this way some examples of terminal streptococcal invasion were excluded. That rheumatic heart disease often precedes streptococcal infection is, according to Thayer's statistics, a characteristic feature, thus contrasting with the rarity of syphilitic aortic valvulitis as the basis for this coccic infection. Though this association of streptococci with rheumatic pancarditis is regarded as due to secondary infection, he admits the possibility that at some future time acute rheumatism may be proved to be dependent on streptococcal infection. But in the meanwhile it is difficult to avoid the conclusion that Poynton and Paine's cases of "malignant rheumatism" are examples of streptococcal infection on a rheumatic endocarditis. In comparing rheumatic and septic endocarditis, Sir Thomas expresses the belief that the rheumatic form will be proved to be specific, whereas the septic is certainly not, unless, indeed, all the septic cases are due to some underlying but unknown infection on which the recognized bacteria are secondarily implanted.

The recognition of non-microbial factors in the production of endocarditis dates at least as far back as 1844, when Sir James Paget pointed out the liability to subsequent disease shown by the pulmonary and aortic valves when congenitally abnormal; this has attracted the attention of Sir Archibald Garrod and of the lecturer, and more recently has been investigated by Sir Thomas Lewis and Dr. Grant (1923) in regard to minute congenital abnormalities, and statistically by Dr. Maude E. Abbott (1925), who, in a collection of 555 congenital cardiac defects "of clinical significance," found acute endocarditis in 98, or 17.6 per cent.

The influence of physical strain in favouring endocarditis, insisted on as a cause of chronic heart disease by the late Sir Clifford Allbutt since 1870, finds support from the lecturer and from Drs. H. J. Starling and Carey Coombs's experience in ex-soldiers who, apparently free from previous cardiac lesions, were, after strenuous service, attacked by chronic infective endocarditis. There is thus a very definite difference from Professor Thayer's careful statistics, which show that 75 to 80 per cent. of infections with *Streptococcus viridans* are implanted on old valvulitis. The lecturer concludes that, whereas in chronic civilian cases there is usually evidence of pre-existing valvular lesions, in acute cases generally and in chronic ex-service cases there is a notable absence of previous valvular disease, though he suggests that even in these there may be some definite though not very obvious congenital defect. He lays stress on the limitation of this chronic infection to the endocardium, the rarity of auricular fibrillation, and the relatively long preservation of myocardial efficiency; this, however, does not necessarily conflict with Thayer's observation of the frequent evidence of past rheumatic myocarditis in streptococcal endocarditis.

With Sir Thomas Horder's criticism of the confusion between the conditions connoted by the labels subacute and chronic bacterial, or, as he prefers to call them, septic endocarditis, many will sympathize, and would be content to apply the term "chronic" to all those which are not acute, and to drop the title "subacute bacterial endocarditis" applied by Libman to the group of cases which he so greatly elucidated,

¹ W. S. Thayer: Studies on Bacterial (Infective) Endocarditis, *Johns Hopkins Hospital Reports*, 1926, vol. xxii, fasciculus 1, pp. 163, 10 charts.

especially as cases sometimes headed "subacute" are found on analysis to be really more drawn out than those formerly designated "chronic." In Professor Thayer's monograph all cases of less than one month's duration are called acute, and all more than this subacute, though such a division is admittedly adopted purely for convenience of analysis.

As regards the articular symptoms, both Thayer and the Lumleian lecturer remark on their arthralgie and fleeting rather than their arthritic characters, and the latter suggests that some cases of pain about the hands and feet may be really due to embolism of the radial or posterior tibial arteries. The café-au-lait tint of the complexion, described by E. Libman, is regarded as evidence of considerable chronicity by Sir Thomas Horder, who associates tenderness over the sternum (also described by Libman) with anaemia, but not otherwise with the disease, and Professor Thayer expressly states that it is not of any special significance. The rarity of pericarditis in streptococcal endocarditis—6 per cent. in Thayer's 110 cases, as compared with 70 per cent. in rheumatic cardiac disease, 28 per cent. in gonococcal, and 19 per cent. in pneumococcal endocarditis—is noteworthy in connexion with the suggested streptococcal etiology of rheumatic fever. Embolism occurred in 88 per cent. of Sir Thomas Horder's chronic cases, and in 96 per cent. of Professor Thayer's chronic streptococcal endocarditis patients coming to necropsy; among the latter cerebral embolism occurred in 34 per cent., as against 16 per cent. in the Lumleian lecturer's 162 cases. Sir Thomas Horder regards Osler's nodes as probably embolic, but admits the absence of any proof that this is true in the case of petechiae. The clinical improvement seen after undoubted infarctions, such as of the spleen, suggests that antibody formation may occur during the changes thus set up.

Libman's description of the bacteria-free stage is submitted to criticism by the Lumleian lecturer, who is anxious to make it clear that negative blood cultures do not mean that the infection has been vanquished, for it may be progressing all the time, and he suggests that the bacteria may be centrifugized out of the circulating blood into the peripheral organs. The treatment is critically considered, and, while not neglecting "hods, both the Lumleian lecturer and trust more to fresh air, sun, and good food. Thayer, indeed, remarks that the chronic cases rarely escape "meddlesome treatment" on account of the importunities of well-meaning relatives. Sir Thomas Horder tried Capps's caecodylate injection treatment on twelve patients, who, if they were not specially benefited, suffered no ill effect.

From an inevitable comparison the thoughtful reader will appreciate the keenly stimulating influence of the Lumleian Lectures, and the value for the formation of definite decisions of the minute analyses to which the Johns Hopkins Hospital material has been submitted by Professor Thayer.

THE ECONOMY BILL AND NATIONAL HEALTH INSURANCE.

THE clauses of the Economy Bill affecting national health insurance have completed their leisurely course through Committee of the House of Commons, and, as was to be expected, have survived the epithets applied to them in Parliament and on the platform. They lend themselves to misrepresentation for purposes of party politics and for those of Approved Society

officials anxious to aggrandize the position and funds of their societies. It is more profitable to examine with less prejudice their intention and their effects on national finance and on health services. This examination has been aided by the reply of the Minister of Health to a deputation representing Approved Societies, a report of which will be found in the SUPPLEMENT this week at page 159. Clauses 1, 2, and 5 of the bill, and certain financial resolutions necessary to these clauses, have been the principal objects of attack. The lines of this attack have been three: (1) that the reduction in the proportion of State grant is a breach of contract unfair to Approved Societies, endangering their financial stability, or at least diminishing their usefulness; (2) that the raid on the Army, Navy, and Air Force Fund is a particularly unworthy form of robbery, as it is at the expense of those who have suffered in health in the service of their country; (3) that making the whole cost of medical benefit a statutory charge on the Insurance Fund is merely paying the doctors disproportionately at the expense of insured persons. It is to be noted that the officials of Approved Societies have not, in general, associated themselves prominently with these last two lines of attack, which have, however, seemed specially acceptable to certain members of Parliament. It may be useful to state, or restate, briefly the present position with regard to these three points.

There are three contributing parties to the scheme of national health insurance—the State, employers, and insured persons. Experience has shown that the total contributions are in excess of the amount required to provide the guaranteed benefits. The present proposals leave the contributions of employers and of insured persons untouched, but reduce the State contribution by more than two and a half millions a year. It must be remembered, however, that, owing to the lowering of the pension age by last year's Pensions Act, the annual contribution from the two other contributory parties will soon be reduced by an amount not far short of the same total. None of the present statutory benefits will be affected by this reduction. The proposals of the Royal Commission for extensions of these statutory benefits will, however, be affected. The second (in order of priority of establishment) of these extensions was to be an additional payment to an insured man in receipt of sickness or disablement benefit of 2s. a week in respect of his wife and of each child under 14 years of age. It appears that the cost of this proposed extension would be almost exactly equal to the reduction of the State contribution made by the Economy Bill in this regard. This particular extension of benefit will, therefore, not be proposed by the Government; but the position of the other treatment extensions recommended by the Royal Commission—consultant and laboratory services, improved provision for maternity, and dental treatment—will be unaffected. As Mr. Chamberlain told the deputation, "It should not be forgotten that societies had been for some time able to provide allowances in respect of children as an additional benefit, but they had not seen fit to do so."

The Navy, Army, and Air Force Insurance Fund was established to receive the contributions paid in respect of service men (who are not members of Approved Societies during service) and to provide ordinary benefits (but not any "additional benefits") for those of such men who are unable on discharge to obtain admission to Approved Societies on account of the state of their health. From various causes the surplus in this fund is very large relatively to its liabilities. The State has been making to the fund

contributions in excess of the needs, and it is proposed to appropriate the greater part of this surplus in relief of the Exchequer. But the stability of the fund for future benefits will not be affected, and those who are entitled to benefit from the fund are to be advantaged in two ways—first by having "additional benefits" granted to them as though the fund were an Approved Society, and secondly by having a special "transfer value" attached to them if they join an Approved Society on discharge, so that they shall at once be fully entitled to any advantage which the society affords. The position of service men will therefore not be worse, but better, under the proposals of the bill, and their future eligibility for additional treatment benefits is of importance, not only to them, but to the medical profession.

The whole cost of medical benefit is, after the end of the present calendar year, to be made a statutory charge on the insurance fund. To most people this will seem only the most elementary common sense, but certain facts might well be pointed out to those members of Parliament and some others who profess to regard such a provision as robbing insured persons in order to overpay the doctors. One of these facts is that medical benefit in this connexion includes not only the remuneration of insurance practitioners (including in this a mileage fund for rural areas), but also the whole cost of drugs and appliances, the cost of administration, and part of the cost of certain other matters ancillary thereto which do not affect the remuneration of insurance practitioners at all. A second fact is that the profession has always asked that its remuneration should be determined on the merits of the case by an impartial authority, and should not be made dependent in the slightest degree upon the varying financial fortunes of any particular portion of the insurance fund. A third fact is that the statutory provision now to be made for medical benefit as a whole, together with its administration, is limited to a maximum of 13s. per insured person entitled to such benefit, and the Government actuary states that "the present cost of medical benefit approaches that to be provided for by the bill." It follows that even a slight increase in the cost of any of the items making up this benefit may affect the adequacy of the maximum amount prescribed by the bill; and it must be made clear by the medical profession that this possible contingency cannot be allowed to influence any demand put forward, either at once or in the future, for a justly adequate remuneration of such services as are given by medical practitioners in connexion with the national insurance scheme.

MULE-SPINNER'S CANCER.

In commenting on the original communications which we had published¹ directing attention to the existence, and demonstrating the probable cause, of a form of occupational cancer till then unsuspected even by those engaged in the industry itself, we stated: "There seems to be no reason why this form of cancer should not be entirely prevented, and probably a commission or committee composed of representatives of employers and workmen, together with technical experts and cancer investigators, would soon find effective means."² We were therefore highly pleased when shortly afterwards the Home Secretary, Sir W. Joynson-Hicks, appointed a committee of investiga-

tion constituted as we had suggested, and we would congratulate its members on the promptitude and thoroughness with which they have conducted their inquiry. An account of their findings appears at page 746. The committee consisted of Mr. F. Holroyd and Mr. E. Judson, representing respectively the Master Spinners' Federation and the cotton operatives, Dr. A. H. Gibson, Professor of Engineering in Manchester University, Dr. Archibald Leitch, director of the Cancer Hospital Research Institute, and Lieut.-Colonel Smallman of the Ministry of Health, with Sir Gerald Bellhouse, chief of the Factory Department of the Home Office, as chairman, and Dr. S. A. Henry of the same department as secretary. Sir Thomas Legge was unfortunately prevented by illness from attending the meetings of the committee.

Much valuable evidence, which would not have been procurable otherwise, was placed at the disposal of this departmental committee. It had been thought at first that the "epitheliomatous ulceration" to which mule-spinners were liable was confined to the scrotum, as in the case of chimney-sweeps, and that the disease had made its appearance only within the last few years; but the report shows that in approximately 25 per cent. of the cases the skin of other parts of the body—arms, legs, face, etc.—is affected, and of the 539 cases which were traced in mortality returns and old hospital records instances were discovered going back for forty years. The earliest age at which the epithelioma was found was 22, and the average age of incidence is in the neighbourhood of 55, or, when reckoned in duration of employment, the minimum time of exposure to the risk was ten years, and the average approximately forty years. The striking fact was elicited that the disease might manifest itself at some considerable period after employment in the mule-room had ceased, even thirty years afterwards, provided that the necessary length of exposure had been undergone. Though the incidence of epithelioma is less than in chimney-sweeps and patent-fuel workers in comparison with the numbers of men engaged, yet, owing to the size of the industry, the cancer of mule-spinners is pre-eminently the occupational cancer of this country. Taking the age period of 55-75 we find that the mortality from cancer of the scrotum in cotton-spinners is one hundred times as great as in the general population.

The committee, after considering carefully and extensively all the possible factors in the causation of the disease, states that "on the analogy of mule-spinner's cancer with other forms of occupational cancer (tar workers, patent fuel manufacturers, paraffin workers, chimney-sweeps, etc.), by the evidence of the occurrence of cancer in petroleum refiners, from the results of deliberate experiments with mineral oils, by our knowledge of the conditions under which mule operatives are exposed to the action of such oils, and by the general consensus of opinion expressed by the medical witnesses who appeared before us, we feel bound to come to the conclusion that the evidence is strongly in favour of this disease being due to the prolonged action of mineral oils." The slight hesitation noticeable in the last phrase is doubtless due to two circumstances for which no thoroughly satisfactory explanation is forthcoming: (a) mule-spinner's cancer is not known in other countries, and (b) though the spinners work with bare feet, which are more thoroughly saturated with oil, yet epithelioma of the feet has been found to be excessively rare. It may be said that the scrotum, as far as one can gather, is a site but rarely affected with

¹ Cancer of the Scrotum: A. H. Southam and S. R. Wilson, *BRITISH MEDICAL JOURNAL*, November 18th, 1922. Mule-spinner's Cancer and Mineral Oil: Archibald Leitch, *ibid.*, November 22nd, 1924.

² *ibid.*, November 22nd, 1924, p. 659.

cancer in the experience of foreign observers, and then only in association with mineral oils; and further, that mortality statistics and the medical inspection of workers are not so highly developed abroad as in this country. It is a strange fact that chimney-sweep's cancer also is practically confined to the British Isles. With regard to predilection for the scrotum rather than for other parts of the skin which may be more exposed, one can only put it that the scrotal skin, for some unknown reason, is more sensitive to the action of such carcinogenic substances. That mineral oil is capable of producing epithelioma on favourable sites is beyond reasonable dispute. That being so, it will be no matter of surprise that the committee is of opinion that other industries entailing an exposure to mineral oils may show a similar liability to skin cancer, and instances of this are coming to light. Indeed, if it had not been for the large numbers of men employed in such a well defined trade as cotton spinning the incidence of the disease might wholly have escaped notice.

The obvious way, therefore, to prevent this form of cancer is to find an innocuous lubricating oil, and this is the chief recommendation of the committee. Dr. Leitch has shown that several mineral oils at least have a carcinogenic property. Whether some mineral oils are devoid of this power is a matter for experiment, though possibly an investigation into the biological effects of animal or vegetable oils, as we understand is being done, might prove more useful. At any rate, the problem of finding such a safe oil must be solved by the oil technologists in conjunction with

meanwhile the committee suggests of the present mule machinery in order to prevent the lubricating oil from being sprayed from the revolving spindles on to the clothing of the workers, insists on the value of cleanliness, and advocates the issue of warning leaflets to all engaged in the industry. Frequent medical inspection is of the utmost importance in order that the preliminary manifestations of lesions may be detected (local skin hyperplasias and warts) and remedial measures undertaken long before the condition becomes frank epithelioma. A trial of voluntary medical examination is to be made, but if this does not succeed then a compulsory system of medical inspection is recommended.

It is very gratifying to find that the whole question has been so expeditiously and thoroughly considered. Within a period of little more than three years, the occurrence of the disease was shown and the cause suggested by Messrs. Southam and Wilson, the cancer-producing properties of mineral oils were demonstrated by Dr. Leitch, and the effective means of prevention were suggested by the Home Office Departmental Committee.

CASSEL HOSPITAL FOR FUNCTIONAL NERVOUS DISORDERS.

THE fourth annual report of the Cassel Hospital for Functional Nervous Disorders at Swaylands, Kent, includes, as in those of former years, a number of interesting details in regard to the forms of mental disorder treated, the subsequent history of the patients, and the modes of psychotherapy adopted. During the year under review (1924) 225 patients were discharged; but as three of these had been in the hospital twice during the year only 222 individuals were dealt with. Twenty of these were readmissions from previous years, and there were therefore 202 new patients who completed their treatment during the year. These are the largest numbers, both as regards the total amount and the number of new cases, in the history of the

hospital. It is thus evident that the hospital continues to cope successfully with the needs of a large number of patients suffering from the minor forms of mental illness. Dr. T. A. Ross, the medical director, continues his excellent practice of giving a statistical survey of the after-history of his cases. Altogether he has been able to keep in touch with 179 of his new patients in 1924, these being classified under the headings of psychoneuroses (114), drug addictions (3), psychoses (30), organic diseases (26), other conditions (6). In the psychoneurotic group 86 are reported as well or much improved; in the drug addicts the results were not so favourable, and Dr. Ross makes the observation that no morphine addict who has been in the hospital since it opened has failed to relapse; in the psychotic group 11 were well or improved. Further reports on cases discharged during the years 1923, 1922, and 1921 are also given, and these enable a summary of the results of all cases heard of subsequent to discharge at the end of 1924 to be made. The fact that, out of 331 psychoneurotic patients discharged since the hospital was opened, 241 are known from their subsequent history to be well or improved by their treatment at Swaylands, indicates that this has been of lasting benefit to a considerable proportion of the cases. Much of the report is taken up with a tabulated statement indicating the sex and age, length of treatment, symptoms, report on discharge, and late report in each case which has been followed up. Dr. Ross devotes the first nine pages of the report to an account and discussion of the methods of treatment which he found to be efficacious in dealing with his psychoneurotic cases. His views are supported by brief clinical accounts of a number of patients he has personally treated in the hospital, together with a few words describing the particular psychotherapeutic measures adopted in each case. From the study of these cases he has arrived at the conclusion that there are illnesses or states of discomfort which depend wholly on ideas, which have no etiological relation with the body, and which can be abolished by a change of mental orientation. Such cases he regards as definitely psychogenic in origin, and he is of the opinion that they would have been made worse by physical methods of treatment. Briefly, the essence of their treatment consisted in making them understand that their symptoms were emotional rather than physical in origin. The next point he emphasizes is that there are several methods of therapeutic approach, the form and complexity of which must depend on the features of each case. Simple explanation he finds quite adequate for a larger number of cases than is commonly supposed. When there is some worry, anxiety, or conflict which is not present in consciousness, however, more elaborate procedures are necessary, and in such cases he has found that success has been attained by some form of the technique of psychoanalysis, combined, when considered desirable, with hypnotic methods. Considerable stress is laid upon the fact that treatment need not always be prolonged in order to be effective; experience has shown that treatment lasting many months is quite unnecessary in a large number of cases. There can be little doubt that there are a large number of persons suffering from psychoneurotic symptoms which greatly diminish their efficiency and happiness who might be greatly benefited by treatment similar to that given at the Cassel Hospital; there would appear to be a need for the development of more clinics for the treatment of minor mental maladies.

DIPHTHERIA IN EUROPE.

ON February 20th (p. 339) we referred to the interesting figures given by the *Journal of the American Medical Association* relating to the mortality from typhoid in Europe. In its issue of January 16th our contemporary has published the results of a similar inquiry concerning the mortality from diphtheria in 1924 in certain European

cities with a population exceeding 100,000. The death rates in Great Britain were, on the whole, very similar to those in the large cities of the United States for the same year, but the range was somewhat greater, being from 0.0 in Southend to 25.7 in Dundee, as compared with the American range from 1.6 to 23.0. Seventy-three per cent. of the British cities had a rate under 10, as compared with 54 per cent. of the cities in the United States. The rates in Glasgow (12.6), Edinburgh (16.8), and Dundee (25.7) were all high, while that of Aberdeen (6.8) was relatively low. It is noteworthy that the average death rate from diphtheria in Scottish cities in the pre-antitoxin period 1858-95 was much higher than that of most English towns. Manchester had a death rate (8.1) which was eight times that of Birmingham (1.0), and London's rate (12.3) was almost exactly like that of New York (11.9). In Germany the death rates ranged from 0.8 (Lübeck) to 19.5 (Mannheim). The death rates in Berlin (2.9) and Munich (5.7) were very much lower than those in London and New York. Fifty-nine per cent. of the German cities had rates of 5.0 and over. In the decade 1880-90 the diphtheria mortality was considerably greater in Berlin and other German cities than in Great Britain. In France the rates ranged from 0.0 in Toulouse to 11.3 in Rouen, which was the only French city with a mortality above 10 per 100,000 in 1924. Paris, where diphtheria seems to have been about the same as in London in the pre-antitoxin era, had a rate of only 5.4 in 1924. Of the other European cities, Geneva was the only one with no deaths from diphtheria. For the most part, even in Northern Europe, diphtheria rates in Europe were very low. It is surprising to find that Rome had a higher diphtheria mortality than the cities of Holland, Belgium, Norway, and Sweden.

CLOSING OF CANTON HOSPITAL.

We are indebted to Dr. James Maxwell, secretary of the China Medical Association, for an account of the circumstances in which the Canton Hospital, which is an Anglo-American institution, has been forcibly closed by a labour organization calling itself the Tsap Mo Kung Se. Dr. Maxwell, in a contribution to the *North China Daily News*, gives an account of this deplorable event, from which it appears that on March 1st an ultimatum was received by Dr. J. O. Thomson, medical superintendent of the hospital, in which it was demanded that the hospital should in future only engage new employees from the labour union, and that extensive additions should be made to wages and holidays. The labour union reserved the right to approve all dismissals of employees. A reply was sent by the hospital directors explaining the basis of the hospital administration and the impossibility of permitting interference by an outside organization. The labour union concerned thereupon closed the doors of the institution forcibly, and cut off the water and electric light supplies, with the result that many seriously sick patients were turned into the streets. The Canton Hospital was the first modern hospital in China, and was opened more than ninety years ago by the American physician, Dr. Peter Parker. We referred on March 21st, 1925 (p. 569), to the deep interest taken in it by the late Dr. Sun Yat-sen, and this outrage will give rise to as much surprise as horror, both in China and elsewhere. It is stated that there is every reason to believe that the Government of Canton took no part in this affair, and, indeed, that it was perpetrated in direct defiance of the Government's orders. The incident would, therefore, appear to be another illustration of the complete disorganization in China, and of the power in isolated cases of Bolshevik organizations. The difficult economic conditions which have prevailed during the last year had been hitherto successfully countered by the hospital authorities,

who had maintained living conditions, wages, food, and holidays for their employees on a higher scale than existed in Canton, though there was a deficit at the end of last year of 20,000 dollars. No financial help was received from the local Government, and contributions from local sources were very small. The hospital was only kept going by donations obtained by American members of the staff from their friends in the United States.

PARASITISM IN EVOLUTION.

SIR ARTHUR SHIPLEY has contributed to the current number of *Science Progress*¹ an article in which parasites are considered in relation not to the host, as is customary in medical and veterinary literature, but to the family to which each zoologically belongs. The reader is taken through the protozoa, the rotifers, the annelids, platyhelminths (flat worms), nematodes (round worms), crustacea, including the strange story of the barnacles, the insects, acarines (mites and ticks), molluscs, to the vertebrates, which contain a few parasitic or semi-parasitic forms. The article is very full of details, and does not give the author many opportunities for those graphic comparisons and brilliant sidelights for which he has trained his readers to look out. But there are a few. Thus, talking of the nemertines, a few of which are parasitic, he says, "these creatures sometimes reach an enormous length, scores of feet longer than a tennis court"; and again, of tapeworms he says, "they may be a few millimetres in length, or they run into metres, almost as long as a cricket pitch." Etymologically a parasite is "one who eats at the table of another, hence one who lives at another's expense." One who lives at another's expense loses initiative and the desire for exertion. So with the animal parasites. Their evolution towards the complete parasite is downward; they lose locomotor and sensory organs their free-living congeners possess, and as they approach parasitic perfection the alimentary organs also. They live, as for instance the tapeworm, by absorbing through their skin the semi-digested or digested liquid food of their host. The one function they retain in fullest measure is reproduction; they produce an incredible number of ova. This is brought about in the tapeworm by the body consisting of an enormous number of segments. There may be hundreds of these, each packed with eggs, and the hinder one is always dropping off and passing out of the alimentary canal of its host, while new ones are always being formed at the other end behind the head: "The whole creature behaves as if it were a recurring decimal." The parasites are a sore trouble to the teleologist, for what good are they? and something of a stumbling-block to the evolutionist, for though their goal seems to be to attain the condition of a mere sac of fertile eggs a great complication is introduced by the fact that nearly all of them must have an intermediate host. Even the gregarine parasite of the earthworm has a life-cycle. It produces a sickle-shaped spore which, it is believed, is picked up by birds, passes out from the bird's body to the earth, and is again swallowed by earthworms; thus "the vicious circle of parasitism" is maintained. The number of eggs produced by parasites is always large, sometimes enormous; a single nematode, it has been calculated, may produce over sixty million eggs. This enormous output is necessary because the offspring has to find the right host. There are many thousand more misses than hits. Doubtless nearly all of the eggs are eaten by some small fry; indeed, somebody has suggested that these worms should be looked upon as cereals of the water. Again, there is the astonishing complication of the life-history of such a creature as a

¹ *Science Progress*. (A Quarterly Review.) April, 1926. London: John Murray. Price 7s. 6d. (by post 7s. 9d.) or 31s. 2d. a year, post free.

certain sacculina parasite of crabs, which, after a short free existence in one stage, attaches itself to a hair of any part of the crab's body. It then pierces with its antennae the soft area at the base of the hair and exudes from its body a small mass of similar cells which, passing down the antennae into the body of the crab, reaches the blood stream and is carried along till it arrives at the intestine of its host in the neighbourhood of the thorax. It attaches itself to the intestine, and throws out roots spreading like those of a tree. They penetrate all through the body of the crab, embracing all organs not absolutely vital. Next a "central tumour," as it is called, grows out from the roots towards the lower part of the intestines, and sends out another set of roots branching all over the body of the crab. The central tumour protrudes to the exterior at the point where the thorax and abdomen join, and when next the crab moults a small hole is left. Through this an external sacculine projects, and the moulting of the crab comes to an end. As Sir Arthur Shipley says, "This amazing metamorphosis is difficult to explain. How the animal finds its way to a hair of the crab, how the undifferentiated mass of cells reaches the exact spot it wishes to attain before the branching begins, and how the 'sacculina externa' comes to the right position for extrusion, are matters of speculation more than of knowledge." However, the curiosities of parasitism are inexhaustible, and we must pass on to the last sentence of the article: "There is practically no animal immune from parasites, and it is quite possible that the number of parasites is not greatly inferior to the number of all the other animals added together." Probably it has not occurred to many to think of the matter in this way, but a little consideration is enough to establish the conviction that probably we have here rather an under- than an over-statement.

JAPANESE VITAL STATISTICS.

INQUIRY into the growth and restriction of populations throughout the world, and the causes thereof, is receiving useful assistance on the statistical side. Professor G. Ichok contributed to the *Presse Médicale* for January 20th an account of the conditions prevailing in Japan since 1912, as indicated by the statistics supplied by the International Office of Public Health up to and including 1916, which is the latest year dealt with so far. In the five years 1912-16 the population of Japan increased from 51,743,600 to 55,224,500; the percentage gain was 14.8. During the first three years of this period the birth rate increased rapidly, but in the last two it fell, and in 1916 the births amounted to only 327 per 10,000 of the population. This figure is, however, far higher than that of the great European countries in 1920, when Italy headed the list with 318 births per 10,000; Scotland and Holland occupied the fourth place with 281; Germany had 271; England 254; and France was placed last with only 215. The high Japanese birth rate is deprived of much of its influence on increase of the population by the high and rising infantile mortality, which in 1912 was 154 births per 1,000 in the first year of life, and in 1916 had risen to 170. The chief cause of this high infantile mortality in Japan is stated by Professor Ichok to be beri-beri, which is responsible for 5,000 to 20,000 deaths each year, one-third of which occur in the first year of life. Much disease and ill health appears also to be attributable to the extreme poverty of a considerable part of the population, combined with bad food and overcrowding. Whereas in 1912 the death rate per 1,000 inhabitants was 20.05, in 1916 it had risen to 21.54. During the same period the highest European mortality was that of France in 1914, which was 18.5; in Denmark and Holland the death rate never rose above 15. In 1910 tuberculosis was responsible for 22.4 deaths per 10,000 in Japan; in 1919 the rate had risen to 23.6,

although this was slightly better than the previous year, when the rate was as high as 25.3. Such figures have naturally caused great anxiety, and a systematic anti-tuberculosis campaign has been started. Other prominent causes of the high death rate are influenza, cholera, plague, "river fever," and a form of epidemic meningitis. Commenting on these statistics Professor Ichok suggests that the continuous increase of the population of Japan notwithstanding these heavy losses is proof of an inherent national vitality.

INFLUENZA.

THE present recrudescence of influenza is widespread, and the deaths in the great towns of England and Wales increased last week from 223 to 294; in London from 48 to 74. Four cities other than London recorded 10 or more deaths—namely, Birmingham (16), Manchester (14), Oldham (15), and Hull (11). A feature of the present year has been the early rise in the notifications of pneumonia, which were already, before the beginning of the year, much above the average, and last week exceeded any week of the corresponding period of 1925; although in 1925 deaths from influenza had already exceeded 350 as early as the sixth week of the year. Probably this points to the recrudescence being of a mild type, which, indeed, seems to be the general experience of clinicians. In 1924 the number of deaths was much larger than in any corresponding week of this year; the maximum was 730 in the tenth week. From the monthly return of the Registrar-General for Scotland it appears that influenza has been increasing also in Scotland. The number of deaths during March from this cause was 100. They have occurred chiefly in the cities of Glasgow and Edinburgh. The number of deaths in Glasgow was 61 and in Edinburgh 27. The Scottish figure for February had been 35 deaths, for January 40, and for December 72.

SIR SQUIRE BANCROFT.

SIR SQUIRE BANCROFT, who died on April 19th, at the age of 84, was a good friend of the voluntary hospitals. He was one of those rather rare wise men who give up work when they have saved as much money as will enable them to live in the manner they prefer. He was a very successful actor-manager, but he and his wife, who contributed so much to this result, made up their minds to retire when yet in early middle age. On two occasions only did he go back to the stage, but for a good many years he gave frequent readings from Dickens's *Christmas Carol*, both in England and Canada; they afforded more than one generation which had never seen him on the stage some taste of his remarkable artistic abilities, and always attracted large audiences. Altogether he thus raised some £20,000 for the voluntary hospitals. He was a member of the board of the Middlesex Hospital; he was chairman of the Foundling Hospital, and showed great and continuous interest in all charities for the benefit of actors. He was a singularly handsome man, tall, with a fine presence, and genial manners which won for him innumerable friends. Without doubt he enjoyed every day of his forty-two years of retirement.

THE KING has promoted Lord Dawson of Penn, G.C.V.O., K.C.M.G., C.B., M.D., Physician in Ordinary to His Majesty, to be K.C.B.; and has appointed Sir Frederick Stanley Hewett, K.C.V.O., M.D., Surgeon Apothecary to His Majesty, to be K.B.E. Lord Dawson and Sir Stanley Hewett were in attendance upon Princess Victoria throughout her recent severe illness.

Statement

ON

THE SPAHLINGER TREATMENT.

PUBLISHED BY AUTHORITY OF THE SCIENCE
COMMITTEE OF THE BRITISH MEDICAL
ASSOCIATION.

DURING the past few years there has been so much discussion concerning the merits of the Spahlinger treatment of tuberculosis that it seems desirable to state clearly the attitude of the Science Committee of the British Medical Association in this matter.

It is common knowledge that a patient suffering from tuberculosis who comes under suitable treatment may for a time at least improve in health and may put on weight, no matter what special form of treatment is used. Nutritious food, suitable exercise, rest, nursing, sunlight, fresh air, and cod-liver oil will all no doubt contribute towards this end, and with such treatment alone some patients get well. Certainly it is not until hygienic measures alone have been shown to be ineffective that serum or drug treatment can be evaluated.

In the past many systems of treatment have been advanced, and in their beginnings many cases of cure were recorded. Koch's original tuberculin is an example of one of the earliest of these cures. Linden's copper lecithin compound, introduced thirteen years ago, effected wonderful cures according to the records; at first nearly all the reports were favourable to its use, but more extended experience has shown the treatment to be valueless. The earlier gold "cures" have passed through a similar stage, and Moellgaard's sanocrysin is still on its trial. Sanocrysin is a known substance, its preparation and mode of use are described, so that the profession is in an ideal position for estimating its value. If the Spahlinger treatment is to be subjected to trial in this country it is essential that the trial be placed in the hands of physicians who are specially skilled in this particular branch of medicine, and who can gauge the probability of the patient recovering with hygienic measures alone.

It is unnecessary to point out that the Science Committee cannot endorse any new method for the treatment of tuberculosis until this has been subjected to a full and independent test. The success of the appeal now being made for money in this country would obviously make such a test financially possible, and we sincerely hope that the money will be obtained for this object, and that an independent and adequately controlled investigation on a sufficiently large scale will be undertaken in this country as soon as the necessary material for treatment becomes available.

The procedure recently followed in the investigation of the claims of sanocrysin appears to offer a good model for such an investigation. We would welcome such an investigation, particularly because of the misconception which seems to have arisen in some quarters to the effect that the medical profession is prejudiced against this treatment. We must, however, disclaim any endorsement of the terms of the propaganda that is being conducted in this country by some of the advocates of the Spahlinger treatment, because many of the statements made cannot be considered established, and can only be established by such a test as we desire to see made and as the Ministry of Health has offered.

Information with regard to M. Spahlinger's treatment has been published from time to time in the *BRITISH MEDICAL JOURNAL*. On May 12th, 1923 (p. 830), an article was printed defining the position at that time. It recalled that in 1922 a medical officer of the Ministry of Health visited M. Spahlinger's bacterio-therapeutic institute at Carouge, Geneva, and reported that although it was not then

possible to express an opinion upon the scientific value of M. Spahlinger's work from the bacteriological standpoint, inasmuch as the details of the technique used in the preparation of the vaccine and serum remained undisclosed, the clinical results obtained in Switzerland and in England warranted further investigation. The Minister of Health promised in Parliament, and intimated to M. Spahlinger, that, with his consent, the Ministry would be prepared to appoint an impartial committee of recognized medical authorities who would watch the results of his method of treatment in a number of clinical cases to be selected by a physician nominated by M. Spahlinger. M. Spahlinger has not yet accepted this offer. The British Red Cross Society made M. Spahlinger an offer of financial assistance under certain conditions, but nothing, so far as we can ascertain, came of this.

M. Spahlinger made a "complete" vaccine and a "complete" serum, but it appears that since 1914 he has practically exhausted his supply of both. M. Spahlinger has continued to make a partial serum, and it has been used for the treatment of cases. The preparation of the complete serum was stated to be a long and complicated process, and M. Spahlinger could not at that time assign any definite date for the production of the serum in quantities sufficient for an experimental investigation such as that proposed by the Ministry of Health.

On June 2nd, 1923 (p. 938), the *BRITISH MEDICAL JOURNAL* published a second article giving further particulars with regard to the vaccines and serums. So far as we are aware or can ascertain, the position with regard to the supply of the vaccines and serums has not changed in any material respect since 1923. Owing to the failure to secure any supplies of the preparations employed, there has been no opportunity of adding materially to the information available in 1923. The best course, therefore, would seem to be to reproduce the article then published. It was as follows:

(Article published in the *BRITISH MEDICAL JOURNAL*,
June 2nd, 1923.)

It will be of interest to give some further particulars about the various products which, as has already been implied, can be classified under two headings—namely: (1) vaccines; (2) anti-serums. A great majority of the cases of tuberculosis treated are given vaccines. Serum is only used in rapidly progressive cases, or in special emergencies.

The Vaccines.

These products are essentially similar to the tuberculins, the use of which from time to time has been advocated. M. Spahlinger has modified and elaborated the methods for the preparation of tuberculin or vaccine, and claims to have obtained products which are more effective than other preparations. Tubercle bacilli are treated by various processes and four vaccines are made. The complete course of vaccine treatment consists of successive courses of injections of each of these four vaccines.

Preparation of the Serum.

What is called the complete anti-serum is made by mixing a large number of (partial) anti-serums, each obtained from a horse which has been subjected to some particular course of injections. The serum of each horse which is added to the mixture is called a partial anti-serum. The partial anti-serums are of different kinds; some are obtained by injecting tubercle bacilli or products of tubercle bacilli into horses, some by injecting other varieties of bacteria which are found associated with the tubercle bacilli in cases of mixed infections. The former group is further divided into bacteriolytic serums and antitoxic serums. The antitoxic serums are prepared by injecting products which are called toxins. These products are obtained from tubercle bacilli by somewhat elaborate methods.

The methods imply nothing new in principle and are essentially those which have been tried sometimes with and sometimes without success in other bacterial diseases.

It is sought (1) to produce active immunity against the tubercle bacillus and its toxins in the patient by the injection of a vaccine, and (2) to make an anti-serum which has antitoxic and bacteriolytic properties and to use this anti-serum to confer passive immunity on a human being.

These are the general principles which have inspired every worker from the times of Pasteur and Behring. The only novelties relate to the technical details and exact methods of preparation of the substances which make up the vaccine and of the various products which are used to inoculate the horses. The exact methods employed are secrets; at any rate the full details which would be needed by anybody who wished to work at the method have not been published. As regards the vaccine, an attempt is made to produce an active immunity by the injection of a series of substances obtained from tubercle bacilli. We do not know of any published experimental data which show that animals inoculated with these vaccines develop immunity against the tubercle bacillus. There remains the evidence to be derived from clinical observations on cases treated with these vaccines. On this point it is not yet possible to form an opinion; it is notoriously difficult to obtain satisfactory evidence unless a very large number of cases are treated and observed under strict experimental conditions, which are difficult to maintain in the ordinary course of medical work.

Effects of the Anti-serums.

It is claimed that the mixture of serums, which is called complete serum, contains both bacteriolytic and antitoxic serums. Antitoxic serums are prepared by injecting horses with preparations which are called ecto-toxins and endo-toxins. We have not seen any published experiments which show, or attempt to show, that these substances are toxins in the sense in which bacteriologists use the word "toxin." In the case of diphtheria bacilli and the tetanus bacilli, as everybody knows, it is possible to prepare a bacteria-free toxin which when injected into animals produces the characteristic features of the disease in question. Nobody has ever succeeded in making a potent ecto-toxin from tubercle bacilli, and M. Spahlinger has not published any experiments which would support the claim that he has been more successful than other workers. The serums which he calls nutritoxins are so called because they are obtained from horses which have been injected with substances which he calls toxins. We do not know of any published work which shows that these serums contained nutritoxins, and as there is no evidence that M. Spahlinger has ever prepared an extracellular toxin, in the ordinary sense of the word, from the tubercle bacilli, it is difficult to say how such evidence can be forthcoming. The claim for the antitoxic properties of the serum is based on the fact that cases of rapidly advancing caseous tuberculosis have been arrested by the use of the serum. As to the value of such clinical evidence it is not possible, from the material so far published, to express any opinion. It is common knowledge that many cases of acute caseous tuberculosis do survive the acute stage and reach a chronic stage, when the patients are able to resume a more or less normal life. The cases of pulmonary tuberculosis showing the signs of large dry cavities, which may be seen in any out-patient department, are sufficient evidence of this.

It is, of course, possible that the elaborate and complicated methods which M. Spahlinger employs may possess advantages, but there is no laboratory evidence that they are any better than what has been done before, and the only evidence there is rests on the observations of some clinical observers who have been favourably impressed by the results which they are obtaining.

If M. Spahlinger and his friends seriously desire to have this method of treatment investigated, it would seem proper and desirable that money should be provided to defray the cost of a satisfactory and conclusive test, and for this reason, as already stated, any appeal for funds would have our good wishes, so far as it might be directed to this end. We do not think, however, that any large sum of money would be necessary for such a purpose. The clinical and experimental tests would, we believe, be undertaken by experienced physicians and bacteriologists in this country without special fee or remuneration. A sum of money might be required to enable M. Spahlinger to provide a supply of vaccine and serum adequate for the test which we have suggested. The Spahlinger treatment has been before the public for more than a dozen years, and it is a remarkable fact that during these years no report has been published which has convinced the medical profession in general that the claims of this method for the treatment of tuberculosis have been established.

Again, we feel it desirable to draw a clear distinction between an invitation to subscribe money for the purpose of testing any method of treatment and an invitation to

subscribe money for the dissemination of a "cure." Before the public is invited to subscribe money for the latter purpose, evidence of a convincing nature of the value of the "cure" should be available. As a general principle the medical profession is opposed to secrecy regarding remedies, but it is understood that M. Spahlinger considers that publication of his methods in detail would at present be opposed to the public interest; the investigation here proposed would impose no obligation on him to disclose publicly the secrets of his laboratory, but only to provide the material necessary for the test.

Before any general appeal for money is made M. Spahlinger should be invited to state the sum of money which would be necessary for the preparation of the supply of vaccine and anti-serum which would be needed for a test.

The details of an adequate test should be left to an impartial committee of physicians and bacteriologists, such as that suggested by the Minister of Health, who have had special experience in the treatment of tuberculosis and the problems of immunity. The tests would be carried out in part in the laboratory, in part in a hospital. As to the vaccine, it should be shown:

(1) That it produces immunity or at least some degree of protection in animals; that is to say, that it has a specific prophylactic action against experimental tuberculosis.

(2) That when it is administered to animals already infected with tuberculosis the disease is arrested, or at least that the extension of the disease is delayed.

(3) That its employment on a large group of tuberculous patients, who have been under skilled and sufficient observation for adequate periods before, during, and after the vaccine injections, has been followed by a degree of improvement which has not occurred in a control group containing an equal number of cases of tuberculosis as similar as possible to those in the experimental group, and maintained under identical conditions, except that the vaccine has not been administered.

As to the anti-serum, it should be shown:

(1) That those substances prepared from tubercle bacilli which are called by M. Spahlinger toxins, and which are used for injection into horses, are in fact toxins in the sense in which the word is used among bacteriologists.

(2) That the "antitoxic" serums contain antitoxins capable of neutralizing the toxins which have been used for the preparation of the antitoxins.

(3) That the bactericidal serums have a destructive or unfavourable effect on living tubercle bacilli either in the animal body or *in vitro*.

(4) That the "whole anti-serum" or any constituent "partial anti-serum" has a specific influence on the progress of tuberculosis in the human subject. Here, again, suitable cases would presumably be divided into groups, the individuals in one of which would receive anti-serum while the other group would provide a control.

We have no reason or desire to discredit the claims and statements of M. Spahlinger and his friends and supporters. But we should be wanting in our duty alike to the medical profession and to the general public if we failed to point out that:

(a) This is a secret remedy in the sense that the exact methods of preparation have never been fully published, and have, in fact, for reasons which seemed sufficient to M. Spahlinger, been withheld.

(b) No investigations carried out under strict experimental conditions which afford direct and convincing evidence of the curative action of these substances have been published.

(c) The scheme above suggested gives a full opportunity of testing the value of the treatment without any public disclosure of the laboratory methods which M. Spahlinger deems it necessary in the meantime to withhold.

THE OPTICAL CONVENTION.

[FROM A CORRESPONDENT.]

SIR DAVID BREWSTER'S remark that of all the sciences optics is the most fertile in marvellous expedients was borne out at the Optical Convention at South Kensington last week, when there were actually long queues at the doors every afternoon to see the wonders exhibited. It is true that the people in the queue were mostly in search of the kind of entertainment popularized in former days by the late "Professor" Pepper, but the interest of the more serious side of the Convention was also well sustained. Papers were read in two sections all day long, a number of popular lectures were given, and there was an exhibition with historical, research, and commercial sections of which it seemed one could never come to the end. Sir Frank Dyson's presidential address was a recital of recent optical triumphs, especially in his own field of astronomy, and also in surveying and telephotography. A lecture greatly appreciated was that given by Professor Elliot Smith on the eye and its functions, in which he traced man's intellectual superiority to his sense of sight, pointing out how in the course of evolution his special characteristics of vision had separated man from the lower creatures, with whom smell was the directive sense.

Production of Optical Glass.

The recent developments in the art of production of glass for optical purposes were ably summarized in a lecture by Mr. W. H. S. Chance and Mr. W. M. Hampton. They included an account of the manufacture of the tinted glasses which have been introduced of recent years. These glasses include, in addition to the "Crookes glass" for ordinary use, a dark green glass to protect the eyes of workmen, such as acetylene and electric welders, from light of extreme intensity as well as from excessive ultra-violet radiations. Another glass with absorptive properties, but used for quite a different purpose, is "calorex"—a roofing glass which has the property of absorbing the maximum amount of heat consistent with transmitting a predetermined amount of light. It has its value in hot climates or in factories at home where it is desirable to keep goods at a low temperature and yet to take advantage of natural daylight. Yet another glass with suitable absorptive properties has been produced for the glazing of buildings where the contents are liable to injury by the chemical action of ultra-violet rays. Then there are special glasses which depend, not as in these cases on the exclusion of certain portions of the spectrum, but on the transmission of certain wave-lengths absorbed by ordinary window-glass. Vitaglass was also shown. Details of this new form of window-glass, which is transparent to a large extent to ultra-violet rays, were published in this JOURNAL a little more than a year ago (April 4th, 1925, p. 664). It has found a use in hospitals and other institutions, and has also been used for the glazing of houses at the Zoological Gardens. Another new form of glass is a "daylight" glass, the result of a number of attempts made during the last twenty years to find a single filter which when used in combination with some artificial source of light—in this case a half-watt lamp—would give a spectroscopically correct match with daylight.

Ophthalmic Investigations.

A small group of papers dealt with ophthalmic optics. One of these which had some "human interest" was a description of the difficulties of the optician in fitting glasses for persons—apparently the generality of mankind—whose faces are asymmetrical. The author, Mr. H. L. Taylor, said that everyone who had paid attention to the fitting of spectacles was aware of the displacement of the right eye in the majority of adults, and this he explained by the evolution of binocular vision resulting in a directing and predominant eye, which, man being right-handed, might be expected to be on the side of that member which had to perform most of the guiding operations. The proportion of adult males, in Western countries, who have asymmetrical features, to an appreciable degree was put by Mr. Taylor at 80 per cent.; in females the proportion is lower, and among people in Eastern countries, whose features are as a rule more impassive, asymmetry

is much less frequent. The perfectly regular face seldom has ocular asymmetry, whereas the possessor of angular or irregular features nearly always shows it in a marked degree. The general rule is to find the right eye further from the nose than the left, the amount of difference being usually 2 or 3 mm. To fit a person with frames and lenses when he has irregular features, and when, as in most cases, he is unaware of it, is one of the worries of the optician. It appears that rimless glasses make the anomalies rather less conspicuous, and also, at the other extreme, that the heavy xylonite and similar rims now worn mask the facial irregularities by drawing attention to their own obtrusive ugliness!

A statistical study of age and sex variations in respect to refractive errors was ventured upon by Mr. W. Swaine, who brought forward a large number of records obtained from sight-testing opticians in this country and from one American ophthalmologist, upon which he prepared certain tables. These showed, among other things, that direct astigmatism—astigmatism, so called, "with the rule"—is more common in youth, while the inverse variety of astigmatism, "against the rule," is more common in middle age. The younger females examined appeared to show a consistently high percentage of direct astigmatism. He also found more hyperopia among females than among males of the corresponding class. Another deduction from some 300 records taken in Devonshire and some 2,000 in London was that myopia bulked less largely in Devonshire than in the metropolis among the defects for which people sought the services of an optician.

Two workers, Mr. H. Hartridge and Mr. R. J. Lythgoe, described some investigations on the influence of illumination on visual acuity. Their conclusion was that while artificial illumination of from 2 to 4 foot-candles is most probably adequate for a variety of purposes when doing fine work, yet only about one-half the full acuity of the eye is achieved at these intensities, and that for the maximum acuity an intensity of from 100 to 200 foot-candles is necessary.

In a long and elaborate paper Mr. E. F. Fincham discussed the mechanism of accommodation. His purpose was to show that the theory of Helmholtz is fully supported by the results of more recent study of both the anatomy of the parts concerned and the observed physiological processes. The two phenomena of the relative immobility of the posterior surface of the lens and the change of the anterior surface to the hyperbolic form, which were believed not to be satisfactorily explained by the Helmholtz theory, are, on the author's showing, quite compatible with that theory and completely explained by it if account is taken of the peculiar properties of the lens capsule, as recently described by Mr. Basil Graves.

A mechanical theory of heterophoric correction was put forward by Mr. J. B. Reiner, who said that physiological evidence showed that the anatomical position of rest of the eyes was one of divergence, and experience of cases in practice suggested that there was not uncommonly a marked difference in this divergence. His theory was that the true anatomical position of rest for each eye was midway between the maximum rotation inward and the maximum rotation outward, the other eye meanwhile being visually fixed upon an object directly in front.

An interesting instrument demonstrated was the myophoriograph, the invention of an optician, Mr. A. J. Esdaile, of Newport, for ascertaining the strength and control of the muscles of the eyes by means of a moving red spot and a white circle, and correctly recording it. From charts made with this instrument Dr. Margaret Dobson read a paper on imbalance or lack of equality in the tension and contractile strength of the eye muscles.

Optical Progress in Many Fields.

One department in which much recent work has been done, as evidenced in the exhibition, is pyrometry. Several examples of the optical pyrometer were on view, some of them based on the measurement of the brilliancy of the light from the glowing material, and others on its colour. Instruments were shown by which stellar temperatures as high as 28,000° C., far exceeding the temperature of the sun, were indicated, and it was stated that the

optical laws on which the pyrometer is founded are so accurate that the figures may be accepted with confidence. Astronomy, as the science most completely dependent on optics, was the subject of some interesting exhibits. One advance illustrated was the verification of the enormous tensivity predicted by Professor A. S. Eddington (who lectured at the Convention) for the faint companion of Sirius. The verification depended upon the possibility of separating the spectra of the two components of this double star, one of which is ten thousand times as bright as the other. The great reflecting telescope at Mount Wilson, the mirror of which has a diameter of 100 inches, proved equal to the task, and thus a deduction from the theory of relativity was also verified—namely, that the wave-length of a spectrum line depends on the gravitational field in which the line originates.

The microscope revealed its many and increasing uses, including its systematic application to the study of metals. In the exhibition were to be seen experiments in television, or the transmission of images at a distance by means of wireless signalling; the results somewhat resembled those yielded by the very early cinematographs, and the piercing whistle or other interference in wireless reception has its equivalent in the "televisor" in the shape of white flashes across the screen or an appearance of snow-flakes. The optical instruments used in aviation were of interest, especially in connexion with the droplets of water the difficulty arising from minute droplets of water deposited on the glasses. Every wearer of spectacles is familiar with the fact that the glass when rather cold can be obscured by light moisture. The designers of aircraft optical instruments, however, have managed to construct sights which cannot "mist over" even when the temperature is reduced to many degrees below freezing point. Among many other objects of interest in the exhibition mention should be made of the exhibit from the optical appliances depot of the Ministry of Pensions which showed the manufacture of artificial human eyes from soda-aluminium glass in all its various stages.

England and Wales.

DERBYSHIRE ORTHOPAEDIC HOSPITAL.
BRETRY HALL, near Burton-on-Trent, was formally opened by the Duke of Devonshire on April 14th, as an orthopaedic hospital, under the control of the County Council of Derbyshire. As the result of the efforts of the late Dr. Sidney Barwise, who, since 1919, had endeavoured to obtain an institution for the treatment of surgical tuberculosis in children, the present building was selected because of the nature of the soil and its elevation above sea-level rendered it very suitable for the purpose. The original purchase price was £23,750, and about £11,500 was spent in adapting the Hall to accommodate fifty crippled children; the Ministry of Health gave £8,000 towards the building. Dr. W. M. Ash, county medical officer of Derbyshire, stated that there were over 800 tuberculous cripples in the county, only 135 of whom were of school age, and 550 were still untreated. Another fifty beds for tuberculous crippled children below the age of 16 was urgently needed, and also an extension of the building to enable treatment of adult cripples to be undertaken under the control of the Derbyshire County Council.

PORTSMOUTH TUBERCULOSIS HOSPITAL SCHEME.
On April 12th Portsmouth Town Council approved unanimously a scheme submitted by the public health committee to reorganize the hospital services under the corporation at a cost of £81,500. Two infectious diseases hospitals are at present in existence at Mount Gold and Swilly respectively. For a large part of the year, when scarlet fever is not rife, each hospital has a half-filled ward with separate administrations and staffs. The new scheme provides for the centralization of all the infectious diseases at the Mount Gold Hospital, thus economizing finance and administration. Two sanatoriums exist—one at Didworthy for early cases, and one at Udal Torre for intermediate and advanced cases. No accommodation is yet available in the borough for adult female cases, inter-

mediate female cases, or surgical cases in adults or children. It is therefore proposed to convert the hospital at Swilly into an orthopaedic hospital and to erect a sanatorium at Efford, adjacent to the tuberculosis colony; such a scheme would obviate sending patients away to distant institutions in Shropshire and elsewhere, and a certain amount of income might be derived from receiving patients from districts where no such treatment is available. The total annual cost of the scheme is estimated at an additional £4,430, which could be provided by rather less than 1d. of the rates.

FAREWELL DINNER TO DR. H. C. PATTIN, NORWICH.
On April 15th, at Norwich, Mr. H. J. Pond, chairman of the health committee of Norwich City Council, gave a farewell dinner to Dr. H. Cooper Pattin, late medical officer of health, who has retired after thirty-three years' service. The Lord Mayor was present, together with the Deputy-Mayor (Dr. G. S. Pope), the Sheriff, and other city officers. Sir George Morse, in proposing the health of the guest, described the steady improvement in public health administration under Dr. Pattin, and referred to the great variety of his interests and activities. Dr. Pattin, in his acknowledgement, quoted statistics from his first report to show how the death rate had fallen from 19 per 1,000 to 12; the infant mortality had fallen from 196 to 58; while in his first year there had been 15 cases of puerperal fever with 10 deaths, during his last year there had been 9 cases with 3 deaths, which could have been still further reduced by improved maternity accommodation.

Scotland.

PRODUCTION OF CERTIFIED MILK.
The first annual general meeting of a society which aims at inducing the public to utilize the higher grades of milk, the Scottish Certified Milk Producers' Association, was held in Edinburgh on April 15th. Lord Hamilton of Dalzell is chairman of the society. A report was submitted showing the activities of the association during the eighteen months since it was formed. Attention was drawn to the fact that the public are liable to be deceived as to the nature of ordinary milk produced without any of the special precautions which are demanded under the Milk Designations Order for the higher grades of milk. This Order, for example, is avoided by vendors putting out ordinary milk in bottles bearing fancy trade designations, and it has been suggested that vendors of such milk should be obliged to label their bottles in such a way as to show clearly that the milk contained therein does not come under or comply with the Milk Designations Order. The demand for certified milk had been gradually increasing, and a decision was recently made by the corporations of Edinburgh and Glasgow that all milk supplied to public institutions under their administration must be produced from certified cows. Another important fact was stated at the meeting by one producer, who said that the greatest demand for certified milk came from industrial districts, where the value of reliable milk supply was being more fully appreciated. The Edinburgh Town Council, at a meeting on April 16th, decided that the corporation should maintain a herd of tubercle-free cows at its farms at Colinton Mains and Oxbgangs, with a view to supplying the various institutions belonging to the corporation with Grade A (tuberculin tested) milk. The consumption of milk in the various hospitals under the corporation amounts to about 165 gallons a day. Grade A (tuberculin tested) milk has been chosen because "certified milk" must be provided in sealed bottles, and this is unnecessary for the wholesale supply and quick consumption that obtains in large hospitals. A trade price has been fixed for Grade A (tuberculin tested) milk, which is only 3d. a gallon above the price prevailing for ordinary market milk. The corporation has been urging for some time that the public should be supplied with high-grade quality milk, and its Public Health Committee has felt that by maintaining a herd of tubercle-free cows the corporation would be providing an object lesson to those who naturally expect it to give a lead to the public in the matter.

STUDENTS' COLLECTIONS FOR HOSPITAL FUNDS.

Following the example of students at Glasgow University, who recently raised over £10,000 for the hospitals in the city, and of the Edinburgh students, who have for some years raised considerable funds by taking part in a pageant held each spring, students in other towns of Scotland are organizing displays for the benefit of their local hospitals. On April 4th a students' day was held in Ayr in aid of the Ayr County Hospital, and from morning till evening bands of collectors assailed citizens and visitors. During the afternoon many thousands of persons thronged the streets to watch an organized procession in which over 600 collectors in costume took part. Over £962 was collected, and altogether, with the proceeds of entertainments and dances, over £1,200 was realized. On the same day students in Stirling, assisted by their friends from Edinburgh, Glasgow, Falkirk, and other centres, took a collection from the public in aid of Stirling Royal Infirmary Building Fund. Here the students also organized a procession, and the proceedings closed with a carnival dance. The proceeds in this case amounted to £1,111.

GLASGOW HOSPITAL SUNDAY FUND.

The annual report of the Glasgow Hospital Sunday Fund shows that the number of churches contributing to this fund during the past year was 526, as against 521 in the preceding year. The average contribution per church was slightly over £17. The total income raised in this way amounted to £10,151, a decrease of £272 as compared with the preceding year. Out of this fund the Royal Infirmary (740 beds) received £4,585, the Western Infirmary (556 beds) received £3,445, and the Victoria Infirmary (288 beds) received £1,784.

CENTRAL MIDWIVES BOARD FOR SCOTLAND.

At a special meeting for the hearing of penal cases, Dr. James Haig Ferguson in the chair, a certified midwife appeared along with her agent, in reply to a citation for contravention of the rules as to notification to the local authority auctent being in contact with a patient suffering from puerperal fever, as also other breaches of the rules. Nurse Anna Blane, assistant inspector of midwives, Kirkcaldy district, gave evidence in support of the charges. After deliberation the Board instructed the secretary to remove the name from the Roll of Midwives and cancel the certificate. A certified midwife was cited to appear in respect of having failed to send for medical assistance in a case of abortion and of other breaches of the rules. The Board found the charges proved and instructed the secretary to remove her name from the Roll and to cancel her certificate. At the same sitting a certified midwife appeared in reply to a citation alleging various breaches of the rules in regard to keeping of records of pulse and temperature, register of cases, etc. Nurse Jane C. Barker, assistant inspector of midwives, Glasgow, gave evidence in support of the charges. The Board resolved that the charges had been proved and instructed that, in order to give the person cited an opportunity of proving amendment, action be postponed for reports at the end of three months from the local supervising authority on her conduct and methods of practice, and also at the end of six months. Failing satisfactory reports being received, her name was instructed *ipso facto* to be removed from the Roll.

Ireland.

MEDICAL INSPECTION OF SCHOOL CHILDREN IN DUBLIN.

A scheme for the medical inspection of school children in Dublin is at present under consideration by the City Commissioners. It is somewhat similar to that which has been in operation for nearly two years in Cork City, where it has been attended with remarkably successful results. For a considerable time past the whole problem of medical inspection for schools throughout the country has been receiving attention from the Department of Local Government and Public Health. The department intends, where possible, to inaugurate the schemes, but inevitably the progress will be slow, as the preliminary work involves

time and close attention to details. The schemes will be administered by the county boards of health, which will be recouped 50 per cent. of the cost. The expenditure involved will be considerable, but in every case steps will be taken to reduce cost as much as possible by utilizing existing institutions in the way of hospitals and dental clinics. In considering the scheme submitted to them the Dublin Commissioners have the benefit of the experience of Cork Corporation, and, latterly, the Cork Commissioner. The advantages of such a scheme to Dublin, with its big slum area and its thousands of poor children, are obvious.

- TUBERCULOSIS: PREVENTIVE INOCULATION.

At the annual general meeting in Dublin of the Royal National Hospital for Consumption for Ireland, Dr. W. M. Crofton, consulting physician to the hospital, said that, while the treatment at the hospital enabled many advanced cases to be arrested, the treatment must be prolonged, and they were always badly damaged people. Under modern conditions such cases should not occur, for, if there was any doubt about a diagnosis, a test could be applied which gave definite information as to whether the patient had tuberculosis or not. The recovery of patients diagnosed in this way and treated by the method used was as certain as anything in the practice of medicine. He hoped that every possible publicity would be given to the question of preventive inoculation. The death rate from tuberculosis in infants born of tuberculous mothers was very high—usually over 90 per cent. For twenty years he had been doing preventive inoculation on members of families in which tuberculosis had occurred, and he knew of no case to develop the disease. The method produced no illness, and was not done with a living microbe, as in vaccination against small-pox. Dr. Nathan Raw had been able to stamp out tuberculosis from a pedigree herd by this method, so that it was possible to produce races of human beings and catilo highly resistant to this disease. The method was simple, inexpensive, and could be carried out by any doctor.

Correspondence.

NON-INFECTIVE ARTHRITIS.

SIR,—All practitioners who have had experience of Drs. Cumberbatch and Robinson's method of treating gonorrhoeal infections by diathermy must have been impressed by the way in which many outlying symptoms disappear following the application of this current to urethra, cervix, prostate, or testicles as the case may be. This holds good not only in cases of arthritis but also for sundry muscular and nervous symptoms. So frequent and so impressive are the generalized benefits following pelvic diathermy that it is an obvious step to try it, particularly when other treatments have failed, on cases that cannot be considered to have a gonococcal basis but are otherwise clinically suggestive. Cases so treated will frequently clear up as quickly and fully as if they had been of a gonorrhoeal origin.

If one accepts the theory that diathermy only acts because of the deep heat produced by the current, then one must assume that in those apparently non-gonococcal cases the history or the pathological examination must be inaccurate or that there are other pathogenic organisms in the pelvic region also susceptible to heat.

If, however, it is admitted that the diathermy current can produce effects not solely attributable to heat (and what physician will deny these who has seen the benefit of this current in cases of pneumonia, poliomyelitis, and hyperpiesia: or what surgeon will doubt who has seen the scars of diathermy fulguration?), then it is not unnatural to suggest, as Drs. Cumberbatch and Robinson have done, that this second action of the current should be on the ovaries in the case of women.

The arguments used by Dr. Warren Crowe in his letter of April 17th (p. 722) are logical and forcible, but are not constructive, as he does not advance any theory to account for the improvement in the cases cited by Dr. Cumberbatch.

Many cases, resistant to all ordinary electrotherapeutic measures, and clinically and pathologically free from active gonorrhoeal infection, have now been treated by me both

CORRESPONDENCE.

at the Royal Free Hospital and in private with pelvic diathermy with a high average of benefit. For a long time I considered the diagnosis was probably inaccurate and that a gonococcal basis existed in all those that derived benefit from this treatment. However, I have been forced from this view by cases that, for one reason or another, had to be considered free from gonorrhoeal taint. For a time also I held the opinion that either the specific nature of the current or the internal fomentation action of it on the prostate or ovaries was responsible for the cures effected. This theory, for clinical reasons and for reasons similar to those given by Dr. Crowe, I have abandoned.

I have therefore searched for some differentiating factor to enable me to select those cases most likely to derive benefit from this treatment, and I find that the patients that respond best are those that have a bilateral zone of hyperaesthesia in the groins about 1 inch broad and 6 to 7 inches long (cf. Henry Head). The method I employ for ascertaining the presence or absence of an area of hyperaesthesia or hyperalgesia is by a small induced current (which I have called the subradic test), and although this method is not one advocated by Dr. Head it has certain practical clinical advantages over either the pinch or pin method that compensate for a course of treatment in these selected cases the zones of hyperaesthesia and/or hyperalgesia either disappear or greatly diminish.

It is, I think, too early to press any definite theory as there are many possible explanations. It may be, for instance, that in these cases we have the diathermy current raising the resistance of tissues to some chronic toxic absorption.

Drs. Cumberbatch and Robinson (April 3rd, p. 612) have done a service in drawing attention to this group of cases and to the beneficial effects of diathermy, which are, not infrequently, more dramatic than those secured by ultra-violet light.—I am, etc.,

C. B. HEALD.

London, W.1, April 18th.

THE "SPECIAL REPORT SERIES" OF THE
MEDICAL RESEARCH COUNCIL.

Sm.—Dr. Major Greenwood states (BRITISH MEDICAL JOURNAL, April 10th, 1926, p. 673) that a report issued under the auspices of the Medical Research Council, and drawn up for this body by "particular investigators" to whom the work was "entrusted"—namely, Dr. M. Young and Mr. W. T. Russell, of the National Institute for Medical Research, with the collaboration of Dr. J. Brownlee, Director of Statistics, Medical Research Council, and Professor E. L. Collis, member of the Statistical Committee of the Medical Research Council—was not a report of the Medical Research Council.

The statement that the authors are personally responsible for their conclusions is natural, but is considerably weakened by the criticisms contained in the introduction, which apparently represent the views of the majority of the Statistical Committee of the Medical Research Council, of which Dr. Greenwood is chairman. It is stated also in which Dr. Greenwood is chairman. It is stated also in the introduction that "a large amount of information... by the courtesy of the Registrar-General has been freely placed at the disposal of the Medical Research Council, acting through their Statistical Committee." (The italics are mine.)

Surely, in the face of all this it is not surprising that I should have referred to the publication as a report of the Medical Research Council; and, having done so, I completely fail to understand how such an interpretation can be considered a "grave offence," or a "discourtesy" to the painstaking authors. I am sure many will sympathize with my inability to appreciate the subtle relationship that evidently exists between the Medical Research Council and its own scientific workers and advisers. I am not considering the position of the Council-aided, really independent, worker. I am glad, however, the matter has now been made clear—namely, that the Medical Research Council assumes no responsibility for reports by its own scientific workers and advisers: possibly the Council is wise. I regret that the letter of Dr. Greenwood should have made necessary this explanation of what he calls a misstatement.

Per contra I should like to ask whether it would not have been more becoming of so distinguished a statistician as Dr. Major Greenwood frankly to have acknowledged the grave error made (see BRITISH MEDICAL JOURNAL, March 6th, 1926), in spite of the warning contained in my paper, by the authors of the report when criticizing my work, instead of attempting to cover them and referring to a fundamental statistical point as "trivial."—I am, etc.,

W. BLAM BELL.

Liverpool, April 17th.

MENTAL IRRITABILITY AND BREAKDOWN
IN THE TROPICS.

Sm.—In the whirl of medical literature and theories Dr. J. W. Thomson (April 3rd, p. 634) has confused my work with that of another observer. What I endeavoured to explain at Portsmouth was, that with high electrical potentials in the winter months epileptics had more fits than they did with the low potential in summer months. I have not made any observations on the electric condition of vitiated air. These were made by Dr. Potter of Armstrong College, and described at the Newcastle meeting in 1921.

I think Dr. Thomson's theory is very reasonable. The electric potential in the tropics is generally less than that of the temperate zones; but, of course, mountainous areas would show a high potential. I am of opinion that a high positive potential stimulates mental activity. I have drawn attention to Thackeray's experience in America:

"There is some electric influence in the air and sun here which we don't experience on our side of the globe: people can't sit still, people can't ruminate. . . . Yesterday as some rain began to fall I felt a leaden cap taken off my brain pan, and began to speak calmly, and reasonably, and not to wish to quit my place."

This is over-stimulation. When a person who from an act has bred a habit, and from a habit a temperament, proceeds to the tropics we might expect him to feel, at first, a sense of capacity to endure; but with the continued absence of a customary stimulant we might prognosticate depression.

The theory fits in with the improvement derived from residence in the hills, because one is then removed to an environment of high potential; but, as in most cases where an explanation is sought for a group of symptoms, economical or physiological, the answer is not in one but in several collateral factors. Exposure to sun can be harmful. I think the late Jack London suffered from this, and that his widow admitted it in a book describing his last cruise in the South Pacific. No doubt isolation, monotony of diet, living amid an alien population, are contributory causes. We (as I have said elsewhere) badly need observations on atmospheric electric variations. In some tropical countries the daily variations are considerable and not become frequent, as in Java. Perhaps people do not become neurasthenic there. One has to eliminate a number of possibilities before one can begin to attribute a part to atmospheric electricity, and unfortunately many people will accept anything if you once mention "electricity" as a possible explanation.—I am, etc.,

GEORGE MAHOMED.

Bournemouth, April 5th.

Sm.—With regard to the Bishop of Singapore's letter on nervous irritability in the tropics (March 13th, p. 503), having been twenty years in the East I venture to offer a few practical suggestions.

The first thing is to rid ourselves of all prejudice, and to realize that we cannot live in the East as we do in England. The natives are healthy enough, and so are the officers of the Indian army, taken as a class. English men are healthier than English women and children in the tropics, because they lead a more open-air life. Ill health in the tropics depends on want of common sense as regards food, drink, constipation, clothing, light, and exercise.

Food.—Modern research teaches that fresh food is essential to man, that it contains vitamins which are destroyed by long

cooking or long exposure to sunlight. In India the cook is trained to overcook and stew everything, from porridge, soup, and vegetables to the meat. Peas and other things are put in cold water and left for hours to simmer—meat the same; the milk is boiled and reboiled many times. All fresh fruit and vegetables are excluded for fear of cholera.

Drink.—Pure water is the best, and plenty of it; four or five big glasses a day is not too much. It should be boiled and cooled, if not obtainable from a reliable spring. Alcohol is most inadvisable.

Constipation is due to improper food, nothing raw in the diet, and to insufficient water to drink. It may be traced also to the use of animal fat for cooking instead of oil, and perhaps chiefly to the wrong posture used during defaecation. The Government Public Works Department in India has standardized a high commode, which would induce constipation in the healthiest. The closet seat should be as low as possible. Observe the native and be willing to learn.

Clothes.—Clothing must admit of a free supply of light and air on the skin. Shorts and a shirt are the proper clothing for hot weather in the tropics. The clergy are the worst offenders, and to see Indian candidates for holy orders in black coats and white collars, perspiration streaming down their faces, is calculated to make both men and angels weep. Prickly heat is due to overclothing, and is never seen on naked skins.

Light.—Light does no one any harm; on the contrary, no one is healthy without light on his skin. As with the air, people can shut themselves up until they become sensitive to every draught and every ray of light, or they can harden themselves to bear sunlight and be the better for it. The harmful rays are the heat rays, and it is better for people to avoid the sun from midday until 3 o'clock; and to lie under a thick tree is better than to be shut up in semi-darkness and stagnant air, as is too often the European custom.

Exercise is essential in the morning and evening. As recent research has shown, the ultra-violet rays are then at the maximum, whereas at midday the heat rays predominate and lead to exhaustion. Contrast two classes in the East. The subaltern, who leads an active life and attends parades, route marches, polo, tennis, dances, and can wear shirt and shorts, keeps hard and fit. The clergy and office workers wear special clothes, designed to keep off all light and air from their bodies, with hard tight collars; exercise is at a minimum, indoor life at a maximum. The sedentary life in the East as led by Europeans sooner or later ends in disaster, because Nature never intended us to live in that way. Note the Indian holy man who gives himself to meditation. Not for nothing is he naked and sits in the sun. The more thinking done the more light required.

I would sum up by saying that to keep well in the tropics, light and air on the skin, exercise, plenty of water to drink, fresh food, fruit, and nuts, and avoidance of constipation are essential.—I am, etc.,

April 15th.

K. VAUGHAN, M.B.Lond.

DR. YOUNG'S CANCER PARASITE.

SIR,—In my letter (BRITISH MEDICAL JOURNAL, April 10th, p. 675) I deprecated much of the looseness and inaccuracy of statement which in discussions on cancer often masquerade as sincere scientific criticism. Dr. Leitch's reply (April 17th, p. 721) is a very complete vindication of this plea. Two of his main statements are demonstrably inaccurate. He affirms that at the end of the test experiment carried out at his laboratory he "learned, for the first time, that it was 'leukaemia' rather than cancer" which I undertook to produce. He states further that "we insisted on controls, which Dr. Young regarded as quite unnecessary." It is obvious that were these statements true Dr. Leitch sweeps the ground from under my feet. So far, however, are they from being true that on May 10th, 1924—that is, before the experiment was commenced—I sent a letter to Dr. Leitch outlining the proposed scope and nature of the experiment, in which I undertook to produce "a progressive lymphomatous lesion of the nature of pseudo-leukaemia and, in an advanced case, of lymphosarcoma." Further, I asked Dr. Leitch to arrange for an adequate number of mice, "say 50 with 50 controls," which he did! These quotations from my letter prove that on both counts Dr. Leitch's statements are misleading, and his inaccuracy in regard to a scientific experiment is as remarkable as it is inexcusable. I have no doubt that when Dr. Leitch consults his correspondence he will see the need for apology.

Dr. Leitch states, moreover, that I was not interested in nor did I wish to see the control animals. The real facts are that Dr. Leitch informed me that only two control animals were alive, the remaining forty-eight, like the dead injected mice, having been thrown away without

examination of the organs concerned. He attempts to minimize the value of my experimental results by the statement that so-called leukaemic patches in the liver "are exceedingly common in laboratory mice. They consist of multiple small foci of lymphocytes and bear no relation to tumours—or even to leukaemia." The futility of this is seen by the description of my experimental lesion which I published in 1922.

"Microscopically the histological picture is that of lymphatic leukaemia, the lymphoid growth being especially abundant in the portal areas and extending in the form of plugs of tumour cells into the surrounding parenchyma. Even in an early case the hepatic capillaries may be filled with lymphocytes. In an advanced case the liver tissue may be ploughed up and destroyed by the invading cells. . . . A close study of the appearances has practically convinced me that the neoplastic cells may, and usually do, originate *in situ* in the liver from the lymphoid nodules which, even in the adult, are constantly present in the normal mouse liver. . . . In many cases the proliferating cells may be found in vessels, the lumina of which may be completely plugged by the tumour cells. Mitotic figures may be present in these intravascular elements."

In the test experiment referred to this obvious leukaemic picture reappeared exactly as in my own previous experiments. In Maud Slye's laboratory, where the condition has been closely studied, it is considered as a malignant tumour, and it has been found to occur spontaneously in only 1.5 per cent. of the animals. It is abundantly clear that Dr. Leitch's "foci of lymphocytes" correspond to the appearance which I italicize in the above quotation! The "certain amount of glandular hyperplasia in the region of the thymus gland" found in two out of the eleven animals ultimately rescued from a mishandled experiment (in one it formed a tumour half filling the thorax!) obviously corresponds to the lesion described by me in 1922, where I state that "in an infected animal this scattered lymphoid tissue may exhibit evidence of hyperplasia in the shape of numerous mitotic figures, and in an invasion of the surrounding structures, large vessels, heart wall, etc." This tumour, which has a well recognized association with malignant types of leukaemia, reappears in Dr. Leitch's test experiment. Had Dr. Leitch taken the trouble to read the paper I sent him before the experiment began, in which I show that these lesions have been produced by the "cancer parasite" he affects to despise, or had he studied the observations of others who have described these very significant lesions, he would have been better able to judge how far the arguments for an essential linking of leukaemia, pseudo-leukaemia, lymphosarcoma, and cancer are justified. He would have been able, as was expected, to adjudicate between my claims and the "several" observers and the "numerous distinguished pathologists" to whom he refers, and behind whose opinions he now seems to find comfort in sheltering himself.

It is unnecessary further to multiply the evidence of prejudice and inaccuracy with which Dr. Leitch crowds his letter. The purpose of this correspondence is amply served with the few instances I have selected. It is interesting to note that, whilst Dr. Leitch has been hoping "to have heard the last of it," increasing evidence has been arriving from other laboratories in support of my work. My reason, however, for embarking on this correspondence was not to argue the validity of my views; it was rather to urge a general plea for fairness and accuracy in scientific criticism.—I am, etc.,

Edinburgh, April 17th.

JAMES YOUNG.

A CORRECTION.

SIR,—On page 611 of the issue of the BRITISH MEDICAL JOURNAL for April 3rd Dr. Alcock quotes my remarks at the Annual Meeting at Bath, and says that I gave as indications for operative treatment in cases of retroversion "sterility, dyspareunia, and prolapse." What I really said was that I seldom operated for uncomplicated retroversion, and considered that the indications for operation were dyspareunia, usually in acquired retroversion, and sterility or repeated early miscarriages without other obvious cause in cases of so-called congenital retroversion.—I am, etc.,

London, W.1, April 20th.

HENRY RUSSELL ANDREWS.

Medico-Legal.

LUNACY CERTIFICATION.

HARNETT v. FISHER.

THE action in the King's Bench Division, before Mr. Justice Horridge and a special jury, brought by Mr. William Smart Harnett, farmer and fruit grower of Newington, near Sittingbourne, against Dr. Henry Holdrich Fisher of Sittingbourne, for damages for alleged negligence in certifying Mr. Harnett, on November 10th, 1912, to be a lunatic and a proper person to be detained under care and treatment, resulted in the jury finding that the defendant had not exercised reasonable care in certifying the plaintiff at a time when the plaintiff was sane, and awarding the plaintiff £500 damages against the defendant. The hearing commenced on April 13th, 1926, and lasted four days. On the fifth day (April 20th) Mr. Justice Horridge heard legal arguments on the question whether the Statute of Limitations pleaded by the defendant deprived the plaintiff of his right of action, and reserved his judgement.

This action was against one of the doctors who originally certified Mr. Harnett as a lunatic, the other doctor, Dr. Penfold, having since died. The former action, brought by Mr. Harnett, was against Dr. Hubert Bond, a Commissioner in Lunacy, and Dr. G. H. Adam, medical superintendent of a private mental hospital at West Malling, Kent, for an alleged joint tort on December 14th, 1912, whereby Mr. Harnett, whilst on parole on a leave of absence order, was returned to the mental hospital. In that action, tried before Mr. Justice Lush and a special jury (see BRITISH MEDICAL JOURNAL, March 8th, 1924, at p. 449 et seq.), £20,000 damages were awarded against Dr. Bond and Dr. Adam jointly, the judge deciding as a matter of law that the defendants were responsible for the whole period of Mr. Harnett's detention in mental hospitals from December 14th, 1912, to October 15th, 1921, when Mr. Harnett escaped, while a further sum of £5,000 damages was awarded against Dr. Bond for detaining Mr. Harnett for three hours at the offices of the Commissioners in Lunacy before he was returned to West Malling. In the Court of Appeal (see BRITISH MEDICAL JOURNAL, April 12th, 1924, at p. 692 et seq.) Bankes, Warrington, and Scrutton, L.J.J., held that there was no evidence upon which the jury could have arrived at their finding that Dr. Adam did not exercise reasonable care, and further held that even if Dr. Bond's act of detaining Mr. Harnett was unlawful it was not the direct cause of the plaintiff's subsequent detention, the many certificates of doctors each constituting a new intervening act breaking the chain of causation. A new trial was ordered against Dr. Bond for the detention at the offices, judgement being entered for Dr. Adam. In the House of Lords (the Lord Chancellor, Lords Dunsedin, Atkinson, Sumner, and Buckmaster) (see BRITISH MEDICAL JOURNAL, March 14th, 1925, p. 533 et seq., May 23rd, 1925, p. 989 et seq.) the decision of the Court of Appeal reversing the judgement of Mr. Justice Lush was upheld.

In the present case the defendant denied negligence, and pleaded that he acted in good faith and with reasonable care, as required by Section 330, Subsection 1, of the Lunacy Act, 1890.

Mr. J. W. J. Cremllyn and Mr. N. L. C. Macaskie (instructed by Mr. H. Coulson) appeared for the plaintiff; and Mr. A. Neilson, K.C., and Mr. T. Carthew (instructed by Messrs. Le Brasseur and Oakley, for the London and Counties Medical Protection Society) appeared for Dr. Fisher.

The Plaintiff's Case.

Mr. Cremllyn, in opening the case for the plaintiff, said Mr. Harnett was born in 1861. After his father's death in 1910 he successfully managed not only his own three farms but also that of his late father for the executors. In a previous action brought by Mr. Harnett against Drs. Bond and Adam it was established that Mr. Harnett was sane on December 14th, 1912. It was on November 10th, 1912, that the present defendant had certified Mr. Harnett to be insane, basing his certificate on facts observed by him when seeing the plaintiff in the street at Newington for a minute or two, and the plaintiff was said to have been excited and to have "called out in a loud voice to everybody," and also on facts related by a younger brother of Mr. Harnett, who was the petitioner for his detention in a mental hospital. These facts were to the effect that the plaintiff rambled about religious matters, that he said he had a call to rescue persons in the Bernal institutions and to draw everybody to Christ, and that he was deeply steeped in sexual matters. Evidence would be called to show that every one of those statements was untrue, but, even if they were true, counsel submitted that they did not justify the plaintiff being certified as a lunatic. The Lunacy Acts did not intend a man to be certified merely because he was a "queer fellow," or was said to be "as mad as a March hare," but only if he was of unsound mind and ought to be kept under care and treatment. The younger brother of Mr. Harnett had admitted that Mr. Harnett was not violent or dangerous either to himself or to anybody else. The Act was intended to protect the in-

dividual against abuses and the public against danger. In any event, there was no urgency in this particular case. In 1908 Mr. Harnett's first wife died of an affection of the throat, and when soon afterwards Mr. Harnett himself became troubled with catarrh he consulted first Dr. Jenkins, a Harley Street specialist, and, secondly, a quack doctor, who unfortunately inoculated him with an antituberculosis vaccine, which Dr. Fisher himself mentioned as a substantial cause of Mr. Harnett's alleged insanity.

The plaintiff gave evidence in support of his counsel's opening. Cross-examined by Mr. Neilson, the plaintiff said that on October 29th, 1912, he was very ill, being in a comatose condition, and "talked nonsense." His mother died in a lunatic asylum from special causes, but there was no history of insanity in either his father's or his mother's family. It was his plan at that time to leave his farm and go preaching for the salvation of souls, if asked to do so. Regarding statements in a certificate for his detention made by the late Dr. Penfold, the plaintiff said it was true that on November 6th, 1912, whilst at tea with his second wife, his mother-in-law, a solicitor, and a solicitor's clerk, he said: "You are all treating me as if I were not in my right mind. Spell parallelogram." They all declined, whereupon he obtained a copy of Webster's dictionary, handed it to the solicitor, and spelt it correctly himself. In reply to the judge he said that he put it as an example of his sanity, not as a test.

Dr. T. B. Hyslop, consulting physician for nervous diseases, and formerly medical superintendent and resident physician at Bethlem Hospital, said he did not consider the facts set out in Dr. Fisher's certificate as to that doctor's own observation of Mr. Harnett sufficient to justify the certificate that the plaintiff was irresponsible and suitable for treatment in a mental hospital. By "irresponsible," he meant that Mr. Harnett was neither dangerous to himself nor to the community. Insanity was a matter of degree.

Cross-examined by Mr. Neilson, Dr. Hyslop said that "unsound mind" was almost universal, but "irresponsibility" and "certifiable insanity" were totally different considerations.

Dr. Risien Russell, consulting physician for nervous and mental diseases, said there was nothing in Dr. Fisher's certificate that gave any indication of Mr. Harnett's insanity, and, that being so, there could not have been reasonable care exercised by Dr. Fisher in certifying the plaintiff. To say that Mr. Harnett was "steeped in sexual matters" was nonsense. Dr. Hyslop had said insanity was a matter of degree, but "degree" did not quite fit the case. One of the things alleged against the plaintiff was that he had said that he had a mission to save souls. It was a big jump, however, from that to the man who said that he was a new prophet come into the world. The witness said he had often been asked to define insanity, but it was impossible to give any definition which would be applicable to all cases. One must know something about the individual's past. There were plenty of eccentric people in this world, and one must know something about the type of man the individual was. The man who had always possessed strong religious principles was in a very different category from the ordinary man about town who, not having gone to church and having no special belief in prayer, suddenly became very religious and proclaimed that he was out to save souls. He did not think it justifiable to certify a man unless he had gone over the border-line.

Mr. Justice Horridge: The question here is whether the doctor went over the borderline in not exercising reasonable care.

The witness, continuing, said the doctor certifying a patient was quite at liberty to get information from other persons as to the patient's insanity, but it was an essential safeguard that the doctor should examine the patient physically. He questioned whether the statement that Dr. Fisher said he had received from someone else could be corroborated. The certifying doctor must also test the patient with regard to his supposed delusions.

Mr. Cremllyn: Are you aware that, under the Lunacy Act, a doctor is not permitted to certify a man to be insane merely on information conveyed to him by others?—Surely, in a borderline case a physical examination is necessary. There might be disease of the brain. If Mr. Harnett had had disease of the brain he would not be here to-day bringing his action.

Mr. Cremllyn: Is there anything in Dr. Fisher's certificate which indicates that anything like a proper and adequate examination was made by him?—No; it clearly reveals that the man who penned the certificate was very hard up for materials on which to certify.

Mr. Cremllyn: Was there, in your opinion, a reasonable, careful, and proper examination of the plaintiff?—There was not. It has been suggested that there are people so obviously mad that it is not necessary to examine them, but Mr. Harnett's case was not like that.

Cross-examined by Mr. Neilson, the witness said that while he did not see Mr. Harnett in 1912, he did not agree that anything he now said was speculative and hypothetical. What he said was based upon the certificate. He did not know what steps Dr. Fisher took, but if Dr. Fisher had seen anything he should be on the certificate. A physical examination ought to be made in every case of certification if it was possible and the patient was not too violent. Excitement and haranguing a collection of villagers might be a sign of insanity, and so might "rambling about religious matters." He did not know what "steeped in sexual matters" meant.

Mr. E. Hambrook, formerly farm bailiff to Mr. Harnett, said that Mr. Harnett always appeared quite sane, and from the time that he recovered from his illness at the end of October until he was taken to the asylum on November 10th, 1912, Mr. Harnett sanely transacted the ordinary farm business with him. He never saw anything to indicate that Mr. Harnett was insane.

Several residents in the district where Mr. Harnett resided also testified that on the day Mr. Harnett was taken to the mental hospital he appeared to them to be perfectly sane.

The Defence.

Mr. Neilson, opening for the defence, first submitted, as a matter of law, that the action was barred by the Statute of Limitations, and, secondly, that the defendant, in certifying Mr. Harnett, acted in pursuance of the Lunacy Act, 1890, in good faith and with reasonable care, and was therefore protected, unless the plaintiff could show that there had been an absence of reasonable care and good faith. The onus of showing this was on the plaintiff, and it had not been discharged.

Mr. Justice Horridge said he would take the verdict of the jury on the question of the exercise of reasonable care, and would deal with the submission that the action was barred afterwards.

Dr. Henry Holdrich Fisher, the defendant, then gave evidence. He said he was M.D. Lond. and L.R.C.P., M.R.C.S., and had been medical officer of the Milton Union and the Sittingbourne district since his father died in 1897. He had had a full course of instruction at Bethlem Hospital and other mental hospitals. On November 10th, 1912, he received a message from the late Dr. Penfold, asking him to go over and see Mr. Harnett for the purpose of certifying him. He drove straight to Newington, where he had a conversation with Dr. Penfold about Mr. Harnett. Dr. Penfold told him that he had complete and sure evidence that Mr. Harnett was not in a state of mental soundness and referred to his recent attack of mania. Dr. Penfold attached vast importance to the plaintiff's letter to the local post office officials, and added that Harnett was "roaring about the street," and matters had come to a climax. From the window of a cottage the defendant himself saw Mr. Harnett rush along the street waving his arms furiously and passing from one group of persons to another gesticulating and muttering something to them. The defendant followed him and put a few simple questions to him, but could get nothing from him. He had been previously told that Mr. Harnett had said that he was collecting witnesses to prove that he was sane. Being of opinion that there was sufficient material to justify his doing so, he made out the certificate.

The Judge's Questions to Dr. Fisher.

By Mr. Justice Horridge: He was not with Mr. Harnett in the street for more than two or three minutes. He was fully convinced then that Mr. Harnett's mind was a blank and that he was mentally unsound. He was certainly not violent or dangerous.

Mr. Justice Horridge: Why did you not take the trouble to ask him about the matters the brother had spoken of? You appear to have asked him nothing.—There are cases where it is futile to ask.

You assumed that he was incapable of telling you anything because he would not speak. How could he tell you anything unless you asked him?—I asked him a few simple questions.

Tell us one single question you asked him.—I must have asked him something, but I cannot say what the phrases were.

It is a serious matter to send a man to an asylum. I should have thought that you could have told us the questions you asked him?—I only remember that it was a simple thing, like "How are you?"

Did he not say to you, "I know you; you attended my wife"?—Yes. Is that any sign that he was not prepared to answer you?—That was of no value to me.

It showed that he knew you and you could have asked him anything you liked. I want you to give some suggestion of some questions you asked. I should have thought that a doctor should get his facts first and then test the man to see whether they were true or not. Did you ask him anything about his letter to the post office?—I do not think I did.

The Juror: My lord, did the witness ask this man any questions at all? His Lordship: He says that he put such small questions that he cannot tell us what they were.

Dr. Fisher: I had to take the man as I found him. I cannot tell you anything more than I have done.

The Juror: There is no definite question at all.

The defendant added that it occurred to him that if he had had Mr. Harnett in a home he might have ascertained more. He thought he had enough upon which to make a certificate. He was absolutely satisfied, as he had sufficient knowledge of the circumstances and of the disease.

Mr. Justice Horridge: Was there any urgency that you should be satisfied on that day?—I could not put the day off because I was asked to go on that day.

Cross-examined by Mr. Cremllyn; the defendant said that the evidence of insanity was meagre but sufficient. He denied the suggestion that he was picked up at the Bull Hotel, Sittingbourne, by Dr. Penfold and driven with a keeper from a mental home to see Mr. Harnett.

Re-examined by Mr. Neilson, the defendant said that he certified Mr. Harnett as long ago as 1912 and the whole thing had passed from his mind. It had been an ordinary incident in his professional life, and he had had no occasion to remember it.

Mr. Justice Horridge: Obviously the defendant has a right to say that it is a hardship to be asked to remember matters after such a lapse of time.

The defendant, continuing, said that as medical officer he had dealt with 247 cases, and he had certified in about a dozen cases before an order was made. He had never had any of his certificates questioned before. If he had not been fully satisfied he would have gone further into the case, but he stopped when he could not elicit any further facts. He wanted to avoid the possibility of retaliation and to leave Mr. Harnett in as calm a state as possible, having regard to the exaggerated state of overexcitability in which he obviously was.

Mr. C. M. Moir, a reporter on the staff of the *East Kent Gazette*, said that, in response to a telegram from the plaintiff to his newspaper, he interviewed the plaintiff on November 9th, 1912, and, from a layman's point of view, he formed the opinion that Mr. Harnett was not right in his mind.

Colonel Richard Locke, Deputy-Lieutenant of the county of Kent and a justice of the peace, who signed the plaintiff's reception order on November 10th, 1912, said he had known Mr. Harnett all his life. Dr. Penfold, who was highly esteemed in the district, told him he was anxious about Mr. Harnett, so he went with Dr. Penfold to the plaintiff's home. Dr. Penfold had warned him not to upset Mr. Harnett, who was exceedingly excitable and some-

times depressed, and when he (witness) saw him he was sitting at the head of the table with his head in his hands. He did not say to Mr. Harnett, "William, you are to go away," immediately he saw him, but he did tell Mr. Harnett later that it would be well for him to go away and have a rest. Mr. Harnett, who was tired and worried, seemed quite willing to go.

Mr. Justice Horridge: If Dr. Penfold, when he left the plaintiff, had said to him: "Mr. Harnett, I am coming around later with a magistrate," would that account for the state of worry and depression in which you found him?—I cannot imagine that Dr. Penfold would have said such a thing.

Mr. Justice Horridge: But Mr. Harnett says that he did say that.—It would have made a difference to Mr. Harnett, no doubt, but I do not think for a moment that Dr. Penfold would say it.

Re-examined by Mr. Neilson, the witness said he had no doubt from what he saw that Mr. Harnett was a proper person to be certified at the time, but he only looked upon his condition as temporary.

Dr. George Henry Adam, one of the defendants in the previous action brought by Mr. Harnett, said that in 1903 he assumed full control of a private mental hospital at Malling Place, Kent, where Mr. Harnett was first received as a patient. The note he made in his case-book after examining Mr. Harnett on his arrival was: "Aspect wild; eyes bulging; actions out of control; jumping from one seat to another; throws his arms about; talking continually on religious subjects; shouts loudly; justifies his behaviour by saying he is acting by the will of God." The witness definitely concluded that Mr. Harnett was of unsound mind. He was bound to take him in under the reception order. He did not know then that Mr. Harnett had had a serious physical illness, or that he had been ill at all. In his statement to the Lunacy Commissioners after the usual seven days, witness said Mr. Harnett was incoherent and rambling, that he chanted aloud from the Bible, talked continually on religious subjects, and believed that he had a special mission to save souls. On December 5th he notified the Commissioners of Mr. Harnett's escape and recapture, on December 10th he reported that the patient's mental condition had improved, and on December 12th he reported that he had allowed him out on twenty-eight days' probation under the care of his brother. On December 14th he heard from the Board of Control that Mr. Harnett was there, and he was fetched back and examined. The record of that examination was: "Patient in a very excited state and much worse mentally than when he went away, and had a delusion that he was going to be infected with various drugs." Later Mr. Harnett was removed to Croydon Mental Hospital.

Cross-examined by Mr. Cremllyn, the witness said he did not think that the original certificates were very strong, but they were strong enough for detention.

By Mr. Justice Horridge: He formed the conclusion that Mr. Harnett was insane, although the jury in the case *Harnett v. Adam and Bond* said Mr. Harnett was sane then.

Further evidence was given by Dr. Ludford Cooper, ophthalmic surgeon, who saw Mr. Harnett at Dr. Penfold's request on October 31st, 1912; by Dr. E. S. Passmore, who received Mr. Harnett into the Croydon Mental Hospital in February, 1913; and by Dr. J. G. Porter Phillips, physician superintendent of Bethlem Hospital.

The Summing Up.

Mr. Justice Horridge, in his summing up, said that the case was one which had rightly been said to be of considerable importance. It was of importance to that unfortunate man, Mr. Harnett. It was of importance to the doctor. It was of importance to doctors because they had to do their duty in giving certificates, and it might well be that if a jury handled such cases heavily in the sense of punishing them, great difficulty might be experienced in getting doctors to certify at all. The case was also of importance to the general public because the public liked to know that, if anybody for whom they cared was to have the same question raised about him as that which had been raised about Mr. Harnett, all due care would be taken before the patient was certified. Dealing with the evidence, his lordship said it revealed that on October 29th, 1912, Mr. Harnett was seriously ill as the result of an injection of tuberculin by an unqualified person. It might be that although a man was thereby caused to do things which might be a bit exaggerated, and might perhaps be in a mental state which might be thought to be unsound, the jury would consider that he had been delirious, had had a temperature of 105°, and was subsequently unconscious, and the jury might think that if these facts were taken into consideration they might explain matters which Mr. Harnett did afterwards, and which without the explanation might strike them as very strange. Colonel Locke, who signed the reception order, was not told one word about the illness Mr. Harnett had had. What did Dr. Fisher's evidence amount to on the point of exercising reasonable care? He had never seen Mr. Harnett before he saw him for a minute or two when Mr. Harnett passed by the window which looked out on the village street. He had a discussion about Mr. Harnett with Dr. Penfold lasting about half an hour, and when he approached Mr. Harnett in the street he only asked him simple questions, none of which he could remember. Dr. Fisher had said that he did not ask Mr. Harnett more questions because he did not want to excite him. That, no doubt, was very kind, but it might mean that because he did not excite him he did not get sufficient evidence upon which to certify him. The Lunacy Act required that a reception order was not to be made unless the practitioner who signed the certificate had personally examined the alleged lunatic within seven days of the order being made. Was Dr. Fisher's examination—making every allowance for the lapse of memory—such as the jury might think sufficient to justify his signing the certificate? Ho (his lordship) thought that they could have very little doubt that Dr. Fisher never attempted in any way whatever to verify any of the statements made about the patient by his

(Mr. Harnett's) brother. Did the jury think that any careful man would consider that a person was of unsound mind solely on the ground that he was "excited," and "harangued the villagers," and "called out in a loud voice"? The jury would have no doubt from the evidence that when Mr. Harnett was said to be in this condition he knew that there was something on foot to put him away. In dealing with these matters they had to give a pretty broad latitude to the honest exercise of a doctor's duty, which was a difficult one to perform.

His lordship, referring to the question of damages, said there had been argument as to how long a part of the plaintiff's detention could be said to be the result of the defendant's certificate, and the plaintiff's counsel had said that he would accept the shortest possible time. The damages must cease to flow directly from Dr. Adam had Mr. Harnett in his care at Malling Place. The jury must not give the plaintiff damages which he would not be able to hold elsewhere. The damages should be moderate and strictly limited to what Mr. Harnett had sustained if he were a sane man taken to the asylum to the knowledge of other people.

The jury, after an absence of an hour, returned the following answers to the questions left them by the judge:

Was Mr. Harnett of unsound mind on November 10th, 1912, when he was certified by Dr. Fisher?—No.
Did Dr. Fisher use reasonable care in certifying him?—No.
Damages?—£500.

A SENTENCE UNDER THE DANGEROUS DRUGS ACT.

The London Sessions (Sir Robert Wallace, K.C., presiding) on April 16th remitted the sentences, totalling six months' imprisonment in the second division, passed upon Dr. Samuel Grahame Connor of Dryden Chambers, Oxford Street, London, by Mr. H. L. Cancellor, the Marlborough Street stipendiary magistrate, for offences against the regulations under the Dangerous Drugs Act, 1920, but decided to allow the fines, amounting to £200, to stand.

The proceedings before Mr. Cancellor, in which the defendant pleaded guilty to technical offences only, were reported in the *BRITISH MEDICAL JOURNAL* of April 10th, at page 677.

Mr. J. A. Hawke, K.C., and Mr. H. D. Roome appeared for the appellant, and Sir Travers Humphreys and Mr. W. B. Purchase appeared in support of the magistrate's decision.

Sir Travers Humphreys said that Dr. Connor in his petition described himself as a medical practitioner of high standing and reputation, and declared that he had been carrying on his profession in London for thirty-three years. Dr. Connor further said he had never previously had any charge against him, and he had never supplied morphine except to a small number of patients, and then only in quantities which he considered would be beneficial. Dr. Connor had submitted that the offences to which he had pleaded guilty were technical in character, inadvertent, and not based upon any improper motive or desire for concealment. The prosecution's case was that Dr. Connor had, during the year 1925, given orders on chemists for a total amount of 850 grains for surgery use. When the summons was served upon Dr. Connor the reply was that he did not understand it, and knew back as about the regulations. As a matter of fact, as far back as December, 1922, Dr. Connor was seen by the police, in regard to the Home Office, and asked to be more careful in regard to the prescriptions he gave for dangerous drugs, as he had been a trifle careless in certain minor matters.

Mr. Hawke, for the appellant, said he did not contest the facts, though he protested that they were heavy. He submitted, however, that a medical man might not be sent to prison for such offences. Of course, it was admitted that Dr. Connor had not kept his books properly, but he had used the morphine for the purposes of obtaining in a perfectly legitimate manner for the use of the treating unfortunate people who were addicted to good results. In several cases Dr. Connor had achieved good results. In the circumstances, and having regard to the whole of the cases and to the fearful consequences which would ensue to Dr. Connor if the magisterial decisions were allowed to stand, the Bench had decided to remit the sentences of imprisonment.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons has this week completed discussion of the Economy Bill, and has also taken the Army Annual Bill Committee stage and the second reading of the Moneylenders Bill. It is proposed to introduce the Budget on April 26th. A meeting of the Parliamentary Medical Committee was summoned for April 21st for a general discussion of medical political subjects.

General Medical Council.

In reply to Colonel Woodcock, Major Hennessy, Vice-Chamberlain of the Household (who answers in the House of Commons for the Lord President of the Council, the Earl of Balfour), said that the five members of the General Medical Council nominated

by the Crown with the advice of the Privy Council under Section 7 of the Medical Act, 1886, are:—For England: Sir Francis H. Champneys, Bt., M.D. (originally appointed 1911, reappointed for further periods of five years, 1916 and 1921; date of registration, March 4th, 1875); Sir George Newman, M.D. (appointed 1919, reappointed 1924, date of registration, November 10th, 1892); Sir Nestor Tirard, M.D. (appointed 1922, date of registration, May 15th, 1876). For Scotland: Sir W. Leslie Mackenzie, M.D. (appointed 1922, date of registration, October 27th, 1888). For Ireland: Sir E. Cocy Bigger, M.D. (appointed 1917, reappointed 1922, date of registration, December 15th, 1883). Colonel Woodcock asked whether the Lord President of the Council would consider setting up a committee of inquiry to investigate and report on the constitution and working of the General Medical Council, as set up by the Medical Act of 1858, with a view to bringing the work and authority of the Council more in accordance with the trend of modern ideas and practice. Major Hennessy referred Colonel Woodcock to the answer given him on December 8th last. (This answer was that the Earl of Balfour did not consider sufficient reason had been shown for setting up a committee of inquiry.) Colonel Woodcock asked whether Major Hennessy was not aware of the great feeling throughout the country engendered by a recent decision of this Council. Major Hennessy replied that he was aware of this question had been taken up by certain sections of the press. If Colonel Woodcock wished to know whether the Privy Council would look into the matter he should put a question down.

Economy Bill.

In committee on Clause 2 of the Economy (Miscellaneous Provisions) Bill Mr. T. Williams moved to postpone Clause 2 for twelve months to 1928. He said that, calculating upon 1924 payments, the clause would mean a reduction in potential benefits of approximately 3s. per person in approved societies. Mr. Chamberlain offered to explain the position with regard to the clause. The main National Health Insurance Act provided 9s. 6d. plus 6d. as the cost of medical benefit and administration expenses. In 1924 it was necessary to arrange for meeting the difference between this 10s. and the actual cost of medical benefit and administration expenses. He understood that the approved societies were asked to meet the difference out of their benefit fund and they refused. Finally, certain moneys were taken up the difference. That arrangement was embodied in the Cost of Medical Benefit Act, 1924. Under that Act the full cost had been met up to the present without charge on the Exchequer. If Mr. Williams's amendment were accepted there would be no statutory provision for the difference between the actual cost and the 9s. 6d. plus 6d. provided in the original Act. The Unclaimed Stamps Fund would be exhausted by the end of this year. Unless the clause were passed in its present form the whole scheme would be thrown into disorder. The amendment was defeated by 244 to 144. On the motion that the clause stand part of the bill, Mr. J. H. Thomas pointed out that the clause had estimated that the extra cost of medical benefit of the approved societies would be £1,900,000 annually, exclusive of the State grant. Mr. Buchanan asked how the clause affected Scotland. Sir Kingsley Wood said there was a special provision that, in addition to the payments out of the 13s. grant which were generally authorized by the clause, the expenses of the provision for a medical service for insured persons to such parts of Scotland as were determined by the Board to be necessary. The 13s. of a medical service for the Board of doctors in the sparsely populated areas of Scotland. Inasmuch as the drug bill was less included areas of Scotland this provision could be made. The provision for special assistance to the doctors in particular sparsely populated areas of Scotland had been put in at the request of the Scottish societies. The Highlands and Islands Medical Service Grant Act, 1913, already made this special provision for the Highlands, and the clause under something was considered its operation. Mr. Lloyd George said their patients saved by the fact that Scottish doctors did not drug their patients as thoroughly as English doctors did. He thought they deserved an extra fee for that. Did the 13s. represent the amount which the Minister of Health had decided should be paid to the doctors, or was it merely a maximum put into the bill for the purpose of calculation? Had the Ministry ever made an arrangement with the doctors on the basis of 13s.? and had they consulted the approved societies with regard to that figure? Mr. Chamberlain said the 13s. was a composite sum. It included the fee which was the subject of agreement with the doctors, and the present comparable amount was 10s. Of the 13s., 9s. went to the doctors for the subject of agreement with the doctors, and 3d. for the Minister of Health in respect of regional medical officers and of central expenses of the Insurance Committees, and 3d. for the cost of administration. A margin of 14d. was put in because the cost of drugs had been rising in the past, and there was no certainty that they had reached finality in the cost of drugs. It would be seen that the 13s. was nearly related to the recommendation of the medical benefit, and strictly followed the recommendation of the Royal Commission. Mr. Wheatley said the House was entitled to know what the people who were receiving now. The clause was added to the bill by 188 to 114.

On Clause 3 Mr. Rhys Davies moved that provision should be made for continuing any additional benefits granted in respect of the surpluses of the first and second valuations. He pointed out that under the bill the Minister could assist any society which was in a deficiency to pay normal statutory benefit. He desired that they should also be entitled to pay such items as additional

maternity benefit, dental treatment and dentures, optical treatment and optical appliances. He calculated that 1,500,000 persons would suffer through a deficiency in their approved societies as a result of the bill's passage. Mr. Chamberlain said Mr. Rhys Davies was not correct in assuming that members of societies which were thrown into deficiency would be worse off. The amendment went far beyond the intention of the bill. Dr. Drummond Shiels said additional benefits were not in the nature of gifts or something outside and beyond the scope of the Insurance Fund. They were an attempt to come nearer the object of the insurance system. A full and complete medical service and adequate financial benefits were designed from the first. Restrictions on these were made by regulations under the Act, principally so that time might be given to test the financial soundness of the scheme. That had now been assured, but it was alarming to find the Minister of Health contemplated that not only might they not get additional benefits in many cases, but even that the benefits secured under the first two valuations might be reduced. Nothing would more tend to slackness of administration in the approved societies than the Government's action. The additional benefits mentioned by Mr. Rhys Davies were absolutely necessary. No medical scheme could be successful which did not provide for efficient dental treatment. In view of the complexity of diseases and the great increase in specialist treatment it was ridiculous to maintain a purely general practitioners' practice for panel patients. Yet it seemed that after the third valuation they would have no specialist medical benefit. They would be left with simply a dental benefit, an oculist benefit, and perhaps a little additional maternity benefit, and some of the more elementary things might even be taken away. Mr. Wheatley asked whether the Minister of Health could rise in the House and deny that the dental service which had been obtained by the insured people of the country had been one of the greatest national boons the country had ever received. It was impossible to have a decent standard of health in this country if the teeth of the people were not properly attended to, and for the first time they were able to obtain for the poorest section of the people through the National Health Insurance scheme what they knew to be one of the elementary necessities of health. Part of the outlet for the surpluses of approved societies had been the assistance of convalescent homes or hospitals in which their members obtained treatment. The whole nation would suffer if this assistance was withdrawn. Another additional benefit was optical treatment, and many members on that side of the House were short-sighted from lack of early provision of optical appliances. The provision for the industrial population. gical appliances to their members made all the difference between great hardship and existence under ordinary standards of comfort. Mr. Chamberlain said that additional benefits were not declared for all time but for a quinquennial period. Mr. Buchanan said he had told a colleague, a doctor, that he was surprised at the medical profession in the House not making a greater fight on this amendment. They were going to make the task of the ordinary doctor in a poor district harder than ever. If the patient could not get decent food and medicine the doctor might as well not be there at all. The Minister of Health should at least secure after 1931 the surgical and dental treatment and the subscriptions to the convalescent homes.

The amendment was defeated by 106 to 163.

On Clause 4 Sir Kingsley Wood said that the Stamps Fund, which had been used for paying the extra amount to the medical men on the panel, would be practically exhausted. But stamps would be lost and cards destroyed again, and the actuaries calculated that sufficient would become available to prevent members of approved societies losing their benefits through prolonged unemployment and to meet the serious increase in the cost of drugs. It was estimated that the deficiency in the Drug Fund would be increased to £600,000 by December 1st.

On Clause 5, proposing the transfer of sums from the Navy, Army, and Air Force Insurance Fund to the Exchequer, Mr. Harney said every member of the House received letters which spoke of poor fellows who entered the army capable of maintaining themselves and those beholden to them, but were now wretchedly hobbling through life, while medical experts were unable definitely to say their condition was brought about through war service. These men were to be robbed. Dr. Vernon Davies hoped the Secretary of War would pass on to the Chancellor of the Exchequer the suggestion that there was a crying need in the service for some of this money. He referred particularly to the question of tuberculosis. The present state of tuberculosis in the Services was extremely unsatisfactory, and so far as he could make out there was no appeal from the decision of the medical authorities on the tuberculosis being attributable to service conditions. No doctor, whether in the Navy, Army, or Air Service, was able, when a man contracted consumption, to guarantee that it was attributable to the conditions of the Service or not.

Sir K. Wood said that the Committee had heard Dr. Davies with interest and sympathy. Under the proposals of the Government a certain section of the men in whom Dr. Davies was interested—the men who were unable to join approved societies—would receive better benefits and assistance. The Government proposed that £400,000 of the surplus from the Navy, Army, and Air Force Fund should be devoted to the interests of these men. The men would receive increased benefits, and, as recommended by the Royal Commission, treatments, such as dental treatment, on the lines of the approved societies' additional benefits. Clause 5 was added to the bill by 229 to 121, and discussion continued on other clauses not of direct medical importance.

During the subsequent debate, on April 20th, on the clause proposing to amend the Education Act and more strictly control

educational expenditure, Dr. Haden Guest said that even in the medical department it was exceedingly difficult to arrive at standards of comparison as between one area and another, or even between two parts of the same area. In London the cost of special services for the schools for blind, deaf, epileptic, and defective children was 15s. 11d. in 1920-21, while in Grimsby it was 1d. Such cases could be multiplied. How could they compare the expenditure of public authorities on the feeding of school children? Some years ago he was one of the medical inspectors of the London County Council, and it was one of his duties to make comparisons between the physical conditions of the children in different areas of London. All the inspectors were trained persons in that respect and all did the same work according to the same standards. Yet to bring their own work to a focus, and to ensure that they were not constantly using different standards in their work, they had to have periodical conferences to deal with one small subdivision of the work of the education authority.

Dr. Drummond Shiels spoke on a Labour amendment to ensure that only new expenditure by local education authorities might be refused grants by the Board of Education. Dr. Shiels said the health of the children ought to come first and their education second. School medical services were still very unsatisfactory, and it was a waste of time and money to provide extra items of education for children who, because of defects of the teeth and tonsils, were unable to profit by them.

The bill was reported to the House without amendment, the third reading debate to be on April 22nd.

Midwives and Maternity Homes.

On April 20th a Standing Committee, with Sir Richard Barnett in the chair, considered the Midwives and Maternity Homes Bill which had been introduced by Dr. Fremantle. Sir Kingsley Wood moved that the phrase in the bill "Any person, not being certified under this Act, who attends a woman in childbirth" be altered to "If any person, being either a male person or a woman not certified," etc. He said that the Ministry of Health desired to prevent any man, not being a medical man, practising in midwifery as had occurred in time past in Durham and had led to malpractices.

Dr. Vernon Davies asked how the amendment would affect medical students. Dr. Fremantle said that any attendance on childbirth by a medical student was under the direction and personal supervision of a duly qualified practitioner, and so the point raised by Dr. Davies would be met. Sir Richard Luce said it was recognized in all medical schools that even when a medical student attended a case alone he had behind him a qualified man at the hospital. Mr. Looker suggested that the courts might interpret the phrase "personal supervision" more strictly. Sir Kingsley Wood thought his amendment met the case, but he would reconsider the case again before the report stage.

A general discussion was permitted on the clause, and in the course of this the Committee debated an amendment by Major Hills, which proposed that no uncertified person should attend women in childbirth otherwise than under the direction and in the presence of a registered medical practitioner, and that any person so acting should be liable on summary conviction to a fine not exceeding ten pounds.

Dr. Fremantle said he had put down a similar amendment at the request of the Central Midwives Board. This would insist on personal direction by a medical practitioner. As a county medical officer he knew that the Act had worked very well, but even in his profession there were a few black sheep—"dichards" who had worked with "handy-women" and would attempt to continue to do so. His proposal was that "handy-women" should only work in the presence of the doctors. At what stage was the doctor to attend? In actual practice it was almost impossible to lay down a precise rule. He said the medical man should be made finally responsible in these cases. If the General Medical Council would turn up their doctors to observe this clause as originally drafted they would get over the difficulty. He offered to withdraw his amendment if the Minister of Health would promise to consult with the General Medical Council.

Sir K. Wood said the Government supported the bill because it was making for the time when every woman in confinement would be looked after by a qualified person. That could not be ensured immediately. The clause in the bill was a great advance on the Act of 1902. In many cases the phrase in the old Act "habitually and for gain" had been avoided. The old clause only enjoined that attendance should be under the direction of a doctor, which could be merely by instruction at the beginning of the case. The new phrase "personal supervision" meant that the medical man actually took charge. If they said "in the presence of" the doctor would have to stay throughout the whole of the confinement. Otherwise no doctor would feel safe. That would be unworkable in practice. He believed that the words in the bill would go sufficiently to ensure great reform. The Central Midwives Board had at one time preferred the phrase "in the presence of," but after consultation with Dr. Fremantle and the Minister of Health the Board was now content with the phrase in the bill. He welcomed Dr. Fremantle's suggestion that the Government should consult the General Medical Council about action to deal with the few medical men who could be said to be "covering" unqualified women. It was always better that a profession should discipline its own members, though he thought the clause in the bill would make such "covering" an offence. Major Hills thought that the courts would interpret "personal supervision" as being the same as general direction. If the courts held that, then a doctor could not be struck off the Medical Register or penalized for carrying out the law. Mr. Rhys Davies asked how the clause would apply.

in villages where there was no qualified midwife and the doctor was miles away. Major Hills said that was provided for as a case of emergency. Sir K. Wood said they need have no anxiety for the woman who attended a neighbour in an emergency in a remote village. They must not permit the odd case to divert them from the purpose of the bill, which was to ensure proper treatment under medical supervision. Sir K. Wood's first amendment was then carried, and the clause was added to the bill.

On Clause 2 Sir Kingsley Wood moved that where a midwife had been suspended from practice to prevent the spread of infection and not for default, the local supervising authority should be compelled to pay compensation. He said that most local authorities did this and he sought to enforce a uniform practice. Major Hills pointed out that the clause in the bill was wider, for it authorized compensation for any case of suspension without default. Dr. Vernon Davies said it was difficult to prove that a midwife was responsible in a case of infection, say by puerperal fever, and he suggested that to stay the spread of infection they should compensate all midwives suspended because of infection. Sir K. Wood said that would be far too wide. He added that the clause proposed that the midwife should appeal primarily to the Central Midwives Board, but that Board did not desire to deal with such appeals. The formula in the amendment followed existing practice and met the only case in which compensation was payable under the old Act. Mr. H. Williams asked if there was any provision to suspend the doctor who became infectious. Sir K. Wood said all that was already provided for by statute. The amendment was then accepted and the clause added to the bill.

Sir Kingsley Wood moved to omit Clause 3, which proposed an annual registration fee for midwives. He said that there were 70,000 names on the Midwives Roll, but that only some 14,000 were habitually practising. He sympathized with the desire to keep the Roll up to date, but many midwives had objected to the fee. Therefore he desired to withdraw the clause. Later he would move a new clause to provide that the Roll should be divided in two parts. The first, to be published annually, would include all the names furnished by the local supervising authorities. The larger list would be published at intervals not exceeding five years, and provision would be made for erasing names which could not be traced. Sir Richard Luce said that many women who practised did not do so in their own districts. A large proportion of nurses qualified as midwives with the intention of practising occasionally. Sir K. Wood said that no midwife could in fact practise unless she gave notice to the local authority, who would furnish her name for the active list. Mr. Rhys Davies said the proposed new clause would give the Midwives Board more power than it ever had before. Sir K. Wood denied this. He had never heard any objection to the constitution of the Board. The clause was deleted, as was the next clause, dealing with male midwives.

On Part II, dealing with the registration of nursing homes, Sir Douglas Newton moved amendments to secure that the authorities supervising maternity homes should be the councils of county boroughs, and such other councils as were authorities under the Maternity and Child Welfare Act, 1918. He suggested that the authority most conversant with local conditions was better suited than county councils to deal with applications for registration. Sir K. Wood opposed the suggestion. Under the Midwives Act the supervising authorities were the county councils and the county borough councils. Now they were proposing, for the first time, with the assent of all parties, the registration of maternity homes, and the bill threw heavy responsibilities on the registering authority. He suggested that the value of the maternity homes should be minimized by minor authorities, but to double inspection, which would be of the country. The suggestion would prove extravagant and wasteful. The Ministry of Health attached great importance to the clause, and doubted whether it could continue to support the bill if the amendment were carried. He was authorized to say that the Central Midwives Board was anxious that the provisions of the bill should be maintained and that the other local authorities should not be introduced. In the debate which followed Dr. Fremantle and Sir K. Wood pointed out that any homes set up by the Government or by a local authority were excepted from the bill, as was any hospital and home for the conduct of which a duly qualified resident medical practitioner was responsible.

Discussion was adjourned until April 22nd.

Registration of Nursing Homes.

When the Select Committee on the Registration of Nursing Homes resumed the taking of evidence on April 20th, allegations of a most serious kind against a cheap nursing home at Wimbledon were made by the Rev. S. K. Anderson, formerly curate in charge of St. Matthew's, Wimbledon, and by Miss Cardross Grant, a registered nurse formerly engaged in parochial visiting at Wimbledon. The testimony of these two witnesses indicated deplorable neglect of patients in regard to overcrowding and defective sanitary arrangements. Mr. Anderson said that this place and other similar ones were advertised as "nursing homes." The same doctor visited four homes of this kind about which the witness knew. All the homes of this description charged between fifteen and twenty-five shillings a week, and in each of them there were about fifteen or twenty patients attended by two or three untrained persons. He brought the same complaint against other cheap nursing homes as against the one he instanced in particular, and in regard to which Miss Grant gave corroborative evidence.

Miss Stephenson, chairman of the Public Health Committee of the Wiltshire County Council, said that council was anxious to

have authority to register. There were practically no nursing homes in the county outside Swindon and Salisbury. She could not say that all the nursing homes in Swindon were satisfactory, but the council was most concerned to register "odd rooms" let habitually by midwives or nurses. There were these rooms all over the country, and some of them were unsatisfactory for midwifery. They only heard of these rooms through district nurses if they were not used for midwifery cases. In the rural areas there was not a great prejudice against sending senile cases to the workhouse infirmary. The cottage hospitals did good work, but she suggested that they should be included in registration. The smaller cottage hospitals would then take up nursing-home work with fees. Some did so now, but few put it in their rules. Such hospitals were now going through a difficult time. Dr. Davies asked whether witness recognized that it was necessary to have rooms in villages to which certain women could go to be confined. Witness said she did, but thought that midwives or others providing this accommodation should be registered. She did not regard the house as more important than the nurse. A doctor in the country would send a patient to confinement in a cottage hospital where the standard was not satisfactory. Many old-fashioned general practitioners were not exacting in such matters, and some cottage hospitals were unsuitable for maternity cases. The "homes" which were ill equipped or badly staffed were usually only for two or three cases, but were run by a qualified nurse or midwife. The chief nursing home in Salisbury charged 5 to 8 guineas a week, but the local doctors were trying to start one at 3 guineas a week. When nurses took patients into their houses the charge varied enormously. The nurse got as much as she could. There was a lack of homes for patients who could pay about 4 guineas a week. In reply to Sir Richard Luce, witness advocated the registration of cottage hospitals because it would raise the status of cottage hospitals which at present had great difficulty in obtaining trained nurses. Answering Dr. Shiels, witness said she knew of cases where a nurse took in a sick person but where there was no medical attention.

The Committee then sat *in camera* to take evidence from a nurse. At the previous sitting, on April 15th, evidence was taken in support of the claim that Christian Science nursing homes should be exempted from registration.

Obituary.

J. W. SMITH, M.B., C.M.Ed., F.R.C.S.Eng.,
Emeritus Professor of Surgery in the Victoria University
of Manchester.

WE regret to announce the death of Mr. John William Smith, which took place on April 13th at Ingleton, Carnforth, Yorkshire, where he went to live when he retired from active practice in 1922.

John William Smith, who was born at Lancaster on August 13th, 1864, the eldest son of Mr. T. D. Smith, belonged to a family which had been settled in the district for centuries. He received his early education at the Royal Grammar School, Lancaster, a foundation dating from the thirteenth century. There he was well grounded in classics, for which he retained a love throughout his life. Having decided to enter the medical profession rather than follow his father in business, he became a student at the University of Edinburgh in 1880. He was no doubt influenced in the choice of a school by the fact that many of his fellow townsmen were Edinburgh medical graduates; among them was the late Sir William Turner, who was born in Lancaster in 1832, and also received his early education at the Grammar School. As a student Mr. Smith attracted the attention of Sir William Turner, who appointed him to be one of his junior demonstrators of anatomy. After graduating with first class honours in 1886 Smith became resident house-surgeon to Mr. John Duncan in the Edinburgh Royal Infirmary. This was a piece of good fortune which profoundly influenced his future career, and never ceased to be a source of satisfaction to him. For John Duncan was a remarkable man and an illustration of the dictum of the late Sir William Dalrymple, given in his shrewd and witty *Dr. Chesterfield's Letters to his Son*, that the largest practices and widest influence are not necessarily in the hands of those men who are most in the public eye. While in Edinburgh Smith, among other honours, had the distinction of being elected a president of the Royal Medical Society.

In 1889 he went to Manchester as junior demonstrator of anatomy to the Victoria University under the late Professor A. H. Young, a former pupil of Sir William Turner. This appointment he occupied for two years, and published several papers on comparative and human anatomy; at this period he became a Fellow of the Royal College of

Surgeons of England (1890). In 1891 he was elected resident surgical officer to the Manchester Royal Infirmary. In this he followed the old-time tradition of the training for the practice of surgery—that a surgeon should first, above all things, be an anatomist. In former times this was almost a fetish, so that the connexion between the anatomy department and the hospital surgical staff was close. It is interesting, though perhaps futile, to speculate how far this alliance or mutual interdependence must have militated against the advance of surgery, for the dissecting room must have been a deadly neighbour to the operating theatre.

On the termination of his resident appointment in 1894 Mr. Smith began private practice as a surgeon. He held various junior non-resident appointments on the infirmary staff, among others that of junior anaesthetist. About this period he interested himself in the medical services of the army. This was years before the creation of the present Territorial Force, and the only outlet for such energies, and the only scope for civilians in this direction, was afforded by the old Volunteer Army Medical Service Corps, or Bearer Company, then under the command of Lieutenant-Colonel William Coates, C.B. In this Mr. Smith obtained a commission, and became an enthusiastic and useful officer. On the call for volunteers in the dark days of the South African war, in December, 1899, a detachment of seventy-two men went out, early in 1900, followed later by a contingent of thirty-four more. Mr. Smith went in command of the first, but on reaching the area of operations was separated from these his own men and detailed for service at Bloemfontein, where he was placed in charge of the surgical division of the famous No. 9 General Hospital (South African Field Force). He served in this capacity for six months, and published an interesting account of his experiences, under the title "Six months with a military hospital," in the *Manchester Medical Chronicle* (1901). During his absence a curious accident happened which might have had a serious effect on his future prospects. There being a chance of a vacancy on the honorary staff of the Royal Infirmary while he was abroad, he left with an intimate medical friend an application, with testimonials, for the appointment, ready to be handed in should the vacancy occur. His friend forgot all about the trust, failed to hand in the documents; and another candidate was duly elected. Happily there was another vacancy within a year, to which Mr. Smith was elected. He thus became honorary assistant surgeon in 1901, attaining the rank of full surgeon in 1910.

On returning from South Africa he continued his connexion with the Volunteer Bearer Company. On the formation of the Territorial Force in 1908 he was given a commission as major in the newly created Royal Army Medical Corps (T.F.), and had command of a field ambulance company. This work strongly appealed to him; he rarely if ever missed a camp, and his enthusiasm and experience on active service made him a most valuable officer. On the retirement of Mr. G. A. Wright from the command of the 2nd Western General Military Hospital, Mr. Smith succeeded him as commanding officer, with the rank of lieutenant-colonel, R.A.M.C. (T.F.). It thus fell to his lot, in conjunction with Mr. F. A. Westmacott, registrar, to mobilize the hospital early in August, 1914. At this period it is difficult to recall or imagine the strain and effort entailed in that task.

The hospital was originally equipped and designed to comprise 500 beds under one roof, and there was the bare nucleus of a trained military staff of officers and orderlies. Except that all contracts for equipment had long been made out and placed and a building ear-marked for the hospital, everything else had to be done *de novo*. A large school in the centre of the town near the Southern Railway centre, with a smaller one a few hundred yards distant, were taken over and rapidly transformed into hospitals. At a very early date patients were being admitted, first from training centres in the district, then direct from the front. The accommodation was rapidly extended again and again. These repeated extensions had to be made at a time when the pressure of work was greatest. The extension went on almost continuously until about 1917, by which time the original base hospital of 500 beds in two

buildings, with a few odd auxiliary hospitals, had increased to a base hospital with 5,000 to 6,000 beds, and some 120 auxiliary hospitals, making a total all told of upwards of 20,000 beds. Mr. Smith retained the command until late in 1915, when he relinquished it to devote himself entirely to surgical work as head of the surgical section of the hospital. These services were recognized by his being appointed deputy lieutenant of the county of Lancaster.

After demobilization he continued in practice till 1922, when, owing to failing health, he decided to retire from active work. Smith was a skilful surgeon, and his judgement and knowledge of human nature were quickly appreciated by his colleagues and patients. His shrewd common sense and his clearly expressed opinions were always recognized in matters of policy in connexion with the medical school. He was specially interested in medico-legal work, and was frequently seen in the witness-box in his capacity as consulting surgeon to the corporation tramways. He also acted as medical referee in the county court for several years.

Mr. Smith was a member of the British Medical Association, and was honorary local secretary of the Annual Meeting at Manchester in 1902. He had been President of the Manchester Medical and Pathological Societies. He published a number of papers in the medical journals, amongst which may be mentioned "Muscular anomalies in human anatomy" and "The surgical anatomy of the rectum," in the *Journal of Anatomy and Physiology*; and two papers in the *BRITISH MEDICAL JOURNAL*—one on excision of the rectum for carcinoma, a record of thirty-four cases from 1904 to 1910 (May 6th, 1911); and the other on atony and prolapse of the large intestine (1920), in which he advocated excision of the displaced colon.

He was married in 1910, and is survived by his widow and two children. The funeral took place quietly at Tatham Church, near Wennington, on April 16th.

SAMUEL BRAITHWAITE, M.R.C.S.,

Late of Egremont, Cumberland.

A FAMILY doctor of the good old-fashioned type, highly respected in his own country-side, passed away at Southbourne on January 26th last in the person of Samuel Braithwaite, late of Egremont, Cumberland. He was educated at St. Bees School, and was articled to Dr. Lawson of Egremont in 1870. Afterwards he studied at the Newcastle School of Medicine and at University College Hospital, London. He gained silver medals for anatomy, botany, dissection, and midwifery. He took the diploma of M.R.C.S. in 1876. He returned to Egremont in 1876, and continued in practice there till 1913, when he retired, and lived at Bournemouth and Southbourne; down to that time he had been for many years a member of the British Medical Association.

At Egremont he took an active part in all local affairs, being chairman of the local board in 1885 and for ten successive years; he was the first chairman of the Egremont Urban District Council, justice of the peace for Cumberland and Westmorland from 1897 onwards, and a prominent Freemason. He became lieutenant in the Egremont Rifle Volunteers in 1884, and was promoted captain in 1888. He was keenly interested in all country sports, and was Master of the Egremont Otter Hounds about 1886, and a member of the Hound Trailing Association. He was chairman of the West Cumberland Fishery Board for many years. In 1915 he won the Bournemouth bowls singles championship. During the war he returned to medical work, and held an appointment at a military hospital in Bournemouth. A life well lived, every day of it.

Dr. JAMES SHEPHERD, who died on March 29th at Aberdeen, in his 80th year, was widely known for his distinguished services in the Indian mission field. He graduated in arts at Aberdeen University in 1868, and obtained the degree of M.B., C.M. in 1871, proceeding M.D. in 1873. While working at Edinburgh for his medical degree he attended the theological hall of the United Presbyterian Church, since he had already determined to become a missionary. He spent the winter of 1871-72 in

Berlin in medical study, and in 1872 commenced medical missionary work at Deoli, in Rajputana. At the special request of the United Presbyterian Church of Scotland he then went to Udaipur, where he founded the celebrated Rajputana mission. His outstanding medical skill and organizing ability, particularly during epidemic outbreaks in this town, won for him the admiration of Rudyard Kipling, who wrote a tribute to him under the title of "A good man's works in the wilderness" (in *Letters of Marque*). In addition to founding the Rajputana Mission Hospital and church, he established a school for Bhils and an asylum for lepers. In 1898 Aberdeen University conferred upon him the honorary degree of D.D., to signalize the completion of twenty-five years' work as a missionary. In 1901 he received the Kaiser-i-Hind medal of the second class, for public service in India, and in 1914 the medal of the first class. He was a member of the British Medical Association.

Dr. JOHN EDGAR PERCIVAL SHERA, who died on April 1st, aged 52, received his medical education at Dublin; he obtained the diplomas L.R.C.P. and S.I. and L.M. in 1895, and the M.D. Brux. degree in 1903. His professional life was almost entirely devoted to mental diseases, and his appointments included those of assistant medical officer to the Kent County Asylum, senior medical officer to the Somerset and Bath Mental Hospital, and medical superintendent of the Bath and Wells Mental Hospital for the last six years. Dr. Shera was a visitor under the Lunacy and Mental Deficiency Acts, and a member of the Royal Medico-Psychological Association. During the war he held a commission in the R.A.M.C., and served in Salonica and North Russia. He was a member of the Somersetshire county panel from 1922 to the time of his death. Great sympathy is felt with his wife and other members of his family.

Dr. GEORGE KILWORTH SHERMAN BIGG, who died on April 4th, aged 71, was educated at Overslade, Rugby, and the Middlesex Hospital. He obtained the diplomas of L.S.A. in 1876, M.R.C.S. Eng. in 1887, and F.R.C.S. Ed. in 1888. He entered the army as surgeon in March, 1880, and served in the Egyptian war of 1882, receiving the medal and the Khedive's bronze star. From Egypt he went to India, where he was staff surgeon at Allahabad. At the expiration of his term of Indian service he served for a short time as staff surgeon at Dover, retiring with a gratuity in the spring of 1890. He then commenced practice in Westminster, and was a Fellow of the Royal Institute of Public Health, examiner to the St. John Ambulance Association, honorary medical officer to Queen Mary's Hostel for Nurses, and honorary surgeon to the Royal Society for the Prevention of Cruelty to Animals. He was the author of several medical and sanitary pamphlets, including *Baby's Health*, *The Anglo-Indian's Health*, *The Wife's Health*, *The Axioms of Diet*, *The Practical Treatment of Cholera*, and *Face and Figure*. He was a member of the Junior United Services Club, and was much respected and beloved by his many friends and patients. For some years past he had been in poor health, and was ultimately compelled to give up active practice in 1923.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

THE following arrangements have been made for the third examination for medical and surgical degrees: Part I (surgery, midwifery, and gynaecology) will begin on June 15th and conclude on June 19th. Part II (principles and practice of physics, pathology, and anatomy) will begin on June 16th and conclude on June 19th. The examination will be held on June 15th, 16th, and 17th, and candidates for the third M.B. and B. examinations should be sent to the Registry by April 27th.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY Council meeting was held on April 15th, when the President, Sir John Bland-Sutton, Bt., was in the chair. It was decided that the Museum in future should be kept open till 5 p.m. all the year round, instead of being closed at 4 p.m. from November to February.

Subjects for Prize Essays.

The subject for the Jacksonian Prize essay for 1927, "The pathology, diagnosis, and treatment of bronchiectasis and abscess of the lung," was approved. The subject approved for the Cartwright Prize for 1926-30 is "The etiology, pathology, and treatment of chronic general periodontitis" (pyorrhoea alveolaris).

Bradshaw Lecturer.

Mr. Ernest W. Hey Groves was appointed Bradshaw Lecturer for the ensuing year.

Fellowship.

The following Members of twenty years' standing were elected Fellows: Mr. George Buckston Browne (London), Mr. Thomas Herbert Bickerton (consulting ophthalmic surgeon, Liverpool Royal Infirmary).

Examiners in Dental Surgery.

Mr. Graham Simpson and Mr. Russell Howard were elected members of the surgical section of the Board of Examiners in Dental Surgery in the vacancies occasioned by the resignations of Mr. Raymond Johnson and Mr. Hugh Lett.

Cartwright Medal.

The Cartwright Medal, with an honorarium of £85, was awarded to James Slim Wallace, M.D., L.D.S.R.C.S., for his essay on "Variations in the form of the jaws, with special reference to their etiology and their relation to occlusion of the dental arches."

Walker Prize.

The Walker Prize of £100 was awarded to Dr. William Ewart Gye. The award was made in pursuance of the following report from the committee appointed to advise the Council in this matter:

"The work of Dr. Gye, which has been very materially assisted by the optical researches of Mr. J. E. Barnard, F.R.S., promises to throw light upon the hitherto unsolved problem of the causation of malignant disease. Taking as his starting-point the pioneer work of Peyton Rous upon fowl sarcoma, Dr. Gye produced from this tumour, by different methods, two fluids. Neither of these fluids when inoculated alone produced a tumour, but an inoculation of the mixed fluids in a healthy fowl produced a sarcoma. The experimenter produced a malignant growth two years which appears to be of extreme factor peculiar to each species of fowl. Dr. Gye has succeeded in producing a virus capable of being obtained from human carcinoma, and he has shown that a virus capable of acting with the 'specific factor' of the fowl to cause fowl sarcoma."

to cause justify:

Diplomas.

Diplomas of membership were conferred upon the following candidates who had passed the requisite examinations and complied with the by-laws:

E. L. Fothergill, J. Gray, A. Holson, M. M. Raouf, S. T. Seccombe, C. C. Ungley.

Licences in dental surgery were conferred upon two successful candidates.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.

THE following, having successfully passed the examination, have been admitted Fellows of the Faculty: P. V. Cherrin, S. S. K. Hattiangadi.

CONJOINT BOARD IN SCOTLAND.

THE following candidates have been approved at the examination indicated:

FINAL EXAMINATION.—Medicine; C

T. MacL. Ormiston, Emma C

J. E. Muirhead.

Of 104 candidates entered, the following passed the Final Examination and have been admitted L.R.C.P. Ed., L.R.C.S. Ed., L.R.F.P. and S. Glasg.:

F. D. R. Wylie, H. Ellison, B. J. Hallion, D. J. Allan, J. L. Clark, R. W. Schuch, J. L. D'Silveira, W. C. Heslop, T. D. Gould, R. A. B. Leakey, W. L. P. Dassanayake, Minnie F. Varley, C. A. B. Leakey, J. C. Sinclair, J. Daly, H. C. V. Cal, G. L. E. P. Sainatsekana, C. L. Millen, D. Isaacs.

son, A. W. Dunn, ang, E. P. Tullio, singhe, O. D. Beet, rk, Ann J. Brown,

The Services.

I.M.S. DINNER.

The annual dinner of the Indian Medical Service will be held at the Trocadero Restaurant on Wednesday, June 16th. Major-General Sir R. C. Macwatt, C.I.E., has been invited to take the chair. Tickets and all particulars may be obtained from the joint honorary secretary, Colonel J. J. Pratt, I.M.S.(ret.), 18, Nevcrn Mansions, Warwick Road, London, S.W.5.

THE PARKES AND THE ALEXANDER MEMORIAL PRIZES.

The Parkes Prize, open to officers of the Royal Navy, Army, and Indian Army of executive rank on full pay, other than professors and assistant professors at the Royal Naval Medical School and of the Royal Army Medical College, is of the value of seventy-five guineas in money and a gold medal; the subject for the next competition will be "The means of spread, and methods of control of bacillary dysentery." The Alexander Prize, consisting of £50 and a gold medal, is open to executive officers of the Royal Army Medical Corps on full pay, other than professors and assistant professors at the Royal Army Medical College. The subject for the forthcoming competition will be "The various aspects of inflammatory middle-ear diseases, with especial reference to their relation to military service." Essays should be sent to the honorary secretary of the prize committee for the respective competitions, Royal Army Medical College, Millbank, S.W.1, on or before December 31st, 1928. Each essay must have a motto, and be accompanied by a sealed envelope bearing the same motto and containing the name of the competitor.

DEATHS IN THE SERVICES.

Major George Pritchard Taylor, D.S.O., M.C., R.A.M.C., died on April 5th, aged 45, at Mhow, Central India, of wounds inflicted by a tiger, which he encountered when out duck-shooting. He was born on September 10th, 1880, educated at Edinburgh, where he graduated as M.B. and Ch.B. in 1908, and entered the army as lieutenant on January 30th, 1909, attaining the rank of major after twelve years' service. He served throughout the recent war, when he was four times mentioned in despatches in the *London Gazette* of June 15th, 1916, May 29th, 1917, December 24th, 1917, and December 30th, 1918. He was awarded the Military Cross on January 1st, 1917, the D.S.O. on January 1st, 1918, and a bar to the D.S.O. on November 7th, 1918. At the time of his death he held the appointment of the D.A.D.M.S. (Sanitary), Mhow Division.

Medical News.

The pharmacological laboratories of the Pharmaceutical Society of Great Britain will be opened by Mr. Neville Chamberlain, Minister of Health, on Wednesday, May 5th, at 3 p.m. As we have already taken occasion to explain, the laboratories have been established by the society for the testing of those therapeutic substances which will be scheduled under the Therapeutic Substances Act, 1925. They comprise, among other substances, such important medicinal agents as digitalis, strophanthus, ergot, and pituitary extract, the purity and potency of which cannot adequately be determined by chemical means. The laboratories are being carried on under the direction of the council of the society, with the assistance of an advisory committee, including, among others, Sir Humphry Rolleston, Sir Nestor Tirard, Dr. H. H. Dale, and Professor W. E. Dixon of Cambridge.

To commemorate the services of Dr. Edmund Ralph Sircorn, late medical officer under the West Ham Board of Guardians, who died on June 1st, 1925, aged 42, an inscribed marble tablet has been placed on a wall in the North-West Ham relief station, and was unveiled on April 8th. Eulogistic speeches were delivered on the services rendered by Dr. Sircorn, and special reference was made to his invariable courtesy and kindness and devotion to the welfare of his patients. The fund for the tablet was raised by a collection from the recipients of outdoor relief, who had particularly desired that some permanent memorial should be erected. Dr. Sircorn had been a member of the British Medical Association for many years, and during the war held the rank of surgeon lieutenant-commander, R.N.V.R.

The presentation portrait of the late Sir Sydney Russell Wells, M.D., F.R.C.P., painted by his nephew, Mr. John Wells, R.I., will be unveiled in the staff room of the Dreadnought Hospital, Greenwich, by Sir Humphry Rolleston, Bt., K.C.B., Regius Professor of Physic at Cambridge, on Tuesday, May 4th, at 3 o'clock. This portrait, which has been subscribed for by his friends and colleagues of Sir Sydney Russell Wells, was on view at the Alpine Gallery in March; it represents him in his robes as Vice-Chancellor of the University of London. Any of his friends who desire to be present at the ceremony may obtain cards of invitation on application to Professor R. Tanner Hewlett, M.D., at the Scamcn's Hospital, Greenwich, S.E.10.

The fourth English-speaking Conference on Maternity and Child Welfare will be held at Caxton Hall, London, from July 5th to 7th inclusive, in connexion with the National Baby Week celebrations. The main subjects under discussion will be the care of the toddler, the care of the mother (expectant, at confinement, nursing, and post-natal), and the father's part in the child welfare movement. Lectures and film displays will be given during the evenings, and arrangements will be made for conducted motor tours to a number of maternity and child welfare institutions in London. A mothercraft exhibition organized by the Central Council for Infant and Child Welfare will be open daily. Further information and tickets for the conference may be obtained from Miss J. Halford, National Association for the Prevention of Infant Mortality, 117, Piccadilly, W.1.

At a meeting of the Illuminating Engineering Society, to be held at the House of the Royal Society of Arts (John Street, Adclphi) at 7 p.m. on Thursday, April 29th, a discussion on school lighting (modern requirements and recent progress) will be opened by Dr. James Kerr (Chairman of the Joint Committee on School Lighting).

THE KING has confirmed the appointment of Dr. Lawson Gifford, District Medical Officer, Kingston, and Dr. David J. Williams as nominated members of the Legislative Council of the Island of Jamaica.

THE Fellowship of Medicine announces that Mr. Gwynne Williams will give a demonstration in clinical surgery at the Royal Northern Hospital on April 27th, at 2 p.m., to which members of the Fellowship and general course ticket-holders are invited. The last week of the course in rology at St. Peter's Hospital begins on April 26th. The Royal Waterloo Hospital will hold a three weeks' course in medicine, surgery, and gynaecology, beginning on May 3rd, on which date also a special course will start at the Central London Throat, Nose, and Ear Hospital. On May 9th the Infants Hospital will begin a two weeks' course with a morning visit on the Sunday to the Venereal Diseases Centre at Thavies Inn; on week-days the sessions begin at 2 p.m. at the hospital. The Royal Westminster Ophthalmic Hospital will hold a course during the first three weeks of May. On May 3rd a course in psychological medicine commences at the Maudsley Hospital and lasts until May 28th. Between the same dates the London Lock Hospital will hold a course in venereal diseases. Syllabuses and programme may be had from the Secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1.

UNDER the auspices of the British Institute of Philosophical Studies, Professor Leonard J. Russell will give a course of nine lectures on science and philosophy on Tuesdays, at 5.30 p.m., at Bedford College for Women, Regent's Park, beginning on April 27th. Particulars of the course can be obtained from the Director of the Institute, 88, Kingsway, W.C.2.

AT Bonn University 375 medical students, of whom 76 were women, were enrolled during the winter session.

THE late Dr. Henry Raynor, of whom an obituary notice was published in our issue of February 20th (p. 351), left estate valued at £41,334.

PROFESSOR ARTHUR HALL, M.D., F.R.C.P., has been appointed consulting physician to the South Yorkshire Mental Hospital, Sheffield.

DR. W. E. GRE will read a paper on the origin of tumours at the meeting of the Section of Surgery of the Royal Society of Medicine on Wednesday, May 5th, at 8.30 p.m. Afterwards Mr. J. E. Barnard, F.R.S., will give a demonstration on microscopical methods.

INVITATIONS have been issued by the Master and Wardens of the Society of Apothecaries to a dinner to meet the Lord Mayor and Sheriffs of London at Apothecaries' Hall, Blackfriars, on Wednesday, May 12th.

A THIRD edition of Sir StClair Thomson's textbook, *Diseases of the Nose and Throat*, will be published shortly by Messrs. Cassell and Co., Ltd. The work has been revised and considerably enlarged, and many new illustrations have been inserted.

PROFESSORS FRIGER of Copenhagen and Marinisco of Bucarest have been elected honorary members of the Société Anatomique de Paris. Professor Léon Frédéricq of Liège has been elected successor to the late Professor Bergonlé in the section of medicine and surgery of the Académie des Sciences.

THE annual provincial meeting of the Fever Hospital Medical Service Group of the Society of Medical Officers of Health will be held at the Medical Institute, Great Charles Street, Birmingham, on Friday next, April 30th, at 2.15 p.m., when Mr. F. Brayshaw Gillespie, assistant surgeon to the Birmingham and Midland Ear and Throat Hospital, will read a paper on ear and throat work in the acute infections.

THE KING has granted authority to Dr. Alexander Granville, C.M.G., C.B.E., late President of the Quarantine Board of Egypt, to wear the insignia of the Second Class of the Order of Ismail conferred upon him by the King of Egypt in recognition of valuable services rendered.

A CONFERENCE on mental welfare will be held, under the auspices of the Central Association for Mental Welfare, in the Central Hall, Westminster, on May 20th and 21st, under the presidency of Sir Leslie Scott, K.C., M.P. On the first day papers will be read by Mrs. Hugh Pinsent, Commissioner of the Board of Control, and Mr. J. Sandeman Allen, chairman of the West Lancashire Association for Mental Welfare, on the proper care of defectives outside institutions. In the afternoon papers on borderland cases will be read by Professor G. M. Robertson and Dr. W. R. Kemlo Watson. Under the presidency of Dr. H. B. Brackenbury the training of teachers for special schools will be discussed on the morning of the second day, when papers will be contributed by Miss M. M. Allan, Mr. G. B. Dodds, and Miss M. N. Russell. In the afternoon Dr. A. F. Tredgold and Dr. F. C. Shrubbs will open a discussion on encephalitis lethargica and its after-effects. It is stated that the Minister of Health will be prepared to consider applications from local authorities, under the Mental Deficiency Act, 1913, whose accounts are subject to Government audit, and from boards of guardians, for sanction for the reasonable expenditure of two delegates. It is announced that a full report of the conference will be published at the cost of 3s. 6d., post free. A public lecture on moral imbeciles will be given by Dr. A. F. Tredgold, on May 20th, at Bessborough House, 1a, Lupus Street, S.W.1, at 5.45 p.m. Tickets for the conference and further information may be obtained from the honorary secretary, Central Association for Mental Welfare, 24, Buckingham Palace Road, S.W.1.

A MEETING of the Society of Superintendents of Tuberculosis Institutions will be held at 122, Harley Street, on Monday, April 26th, at 3 p.m., when papers will be read by Dr. F. R. Walters, on some needs and indications for treatment in pulmonary tuberculosis; by Dr. F. A. Lucas Hammond, on phthisical psychosis; and Dr. S. Roodhouse Gloyne, on the pathology of pleural adhesions in tuberculosis.

DR. C. VER HEYDEN DE LANCEY, L.M.S.S.A. and L.D.S.R.C.S.Edin., who is a British subject, has been appointed oral and dental surgeon to the King and Queen of Italy, the Royal Household, and the Prince of Hesse.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9561, 9562, 9563, and 9564** (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR of the **BRITISH MEDICAL JOURNAL**, *Antiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER

(Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medicera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

LETTERS, NOTES, ETC.

THE PROCEDURE OF THE GENERAL MEDICAL COUNCIL.

"HINDUSTAN," a British practitioner in India, writes: It seems to me that the present criticism of the General Medical Council in the public press at home is not due to any lack of appreciation by the public of the need of such a body to prevent the growth of abuses which would inevitably arise were the Council nonexistent; but it is one of our national characteristics to regard

with suspicion the decisions of tribunals empowered to pronounce summary judgments without appeal, and for this reason those of a professional tribunal like the General Medical Council, which can to all intents and purposes determine without appeal the career of a professional colleague, are particularly suspect. I have been in the habit for many years of reading the proceedings of the General Medical Council, as reported in the **BRITISH MEDICAL JOURNAL**, and am convinced that the decisions of the Council are almost invariably both just and tempered with mercy. Nevertheless, I am in agreement with those who resent the practical absence of appeal from the judgements of the Council. The General Medical Council being under the Privy Council, any practitioner struck off the *Register* has, it would appear, the right of appeal to the Privy Council itself. This being so, I would suggest that it should be arranged that in future such appeals should be referred for consideration by the Privy Council to its Judicial Committee, that very illustrious body which is the highest court of judicature in the Empire. Were this done public opinion would be reassured and much irrelevant criticism of the Council from time to time in the public press obviated.

"NATURE STUDIES IN OBSTETRICS."

DR. CHARLES J. HILL AITKEN (Kilnhurst, near Rotherham) writes: In your leading article of May 16th, 1925, "Medical education: two lay views," you quoted from Mr. Flexner—Students "enter the hospital schools and with rare exceptions soon settle down to clinical study at a level much below the level of their physiological training." Perhaps graduates approach their work in the same way. In obstetrics we apply forceps, clear out placentas after miscarriage, etc., forgetting that, as someone has said, the uterus is a very efficient organ and well able to do its own work. The following nature studies in obstetrics show what the uterus can do: (1) The second of twins not being born I was sent for. I advised delay, and two days later the second child was born without any complications. (2) A patient miscarried. The afterbirth was retained. I saw no indication for hurry, so we waited. Four days later the uterus contracted energetically and expelled a healthy placenta and membranes. The patient certainly lost some blood, but was up and about a week later. I was informed by the neighbour in attendance that on one occasion she had waited a week for the afterbirth. (3) Fourteen days after an incomplete miscarriage a patient sent for me because she had a foul-smelling discharge. Her temperature was 105°. Hesitating to take on myself the responsibility of leaving this case to the uterus, I arranged for the removal of the patient to hospital. While waiting for conveyance labour pains set in and a putrid mass (placenta and membranes) was deposited on the bed. A year later there was a full-time normal birth. (4) A multipara fell in labour on the seventh month. Following a great discharge of liquor amnii the uterus rested. The presentation was head and cord. I judged I was in for turning; however, I decided to await nature action before interfering. Ten hours later the uterus resumed its work and in four pains delivered foetus and afterbirth "in a mass." There was no haemorrhage.

TRIPLETS.

DR. FUKUSHIMA (Rangoon) sends us a note of a case of triplets, which occurred recently in her nursing home. A Madras Hindu lady of about 39 years of age (seventh pregnancy) was delivered of a male child on February 21st, 1926, at 7.5 p.m. with head presenting; at 8.10 p.m. she was delivered of a female child, also head presenting; and at 8.30 p.m. another female child was delivered with breech presenting. She suffered from no pains after the delivery of the first child. The respective weights of the infants were 5 lb. 3 oz., 5 lb., and 5 lb. The male child had a separate sac with its cord, and the females were in one sac with separate cords originating from one placenta. All three children look alike and well developed. An early diagnosis of more than one foetus was made from the physical signs.

ANTIMONYAL CUPPS.

DR. GEORGINA F. MALDEN (Ayr) writes: In connexion with Sir StClair Thomson's article on antimonyal cupps I think the following quotation may be of interest: In *Patronage*, a novel by Maria Edgeworth, published in 1813, occurs: "Mr. Panton seemed to be much struck with the account of bottles made of antimonyal glass, which continue, for years, to impregnate successive quantities of liquor with the same antimonyal virtues." The account is one of medical anecdotes told by a young physician to an elderly hypochondriac. Apparently antimonyal glass then existed, or was believed to do so.

MEDICAL GOLF.

THE final of the Medical Golfing Society's knock-out tournament will be played between Mr. Joseph Canning, who defeated Squadron Leader A. J. Brawn, and Dr. E. Ravensworth Hart, who defeated Dr. D. S. Gordon.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 45, 47, 50, and 51 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 48 and 49.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 100.

A Lecture

ON

THE PRINCIPLES OF TREATMENT OF PULMONARY TUBERCULOSIS.*

BY

CLIVE RIVIERE, M.D.LOND., F.R.C.P.,

PHYSICIAN, CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, AND EAST LONDON HOSPITAL FOR CHILDREN.

CONTRARY to common belief pulmonary tuberculosis is one of the most curable of infective diseases. Many of us sitting here have weathered it in its slighter forms, and even the more severe outbreaks are very amenable to proper treatment. Why, then, it must be asked, is the disease responsible for so large a death roll? The reasons for this lie far more in human nature and our social conditions than in any failure on the medical side. Neglect and ignorance delay the diagnosis, and impatience and lack of opportunity prevent treatment being carried through to a cure. It has been said by some that the sanatorium treatment of phthisis is a failure, but this is far from true. It is, in fact, a wonderful success; but on account of impatience and lack of opportunity it is rarely given a chance of carrying a case through to the stage of cure. Compare with it the institutional treatment of surgical tuberculosis—admittedly a triumphant success. Where does the difference mainly lie? Undoubtedly in this—that for these cases, mostly children, the average time of treatment runs into years, till, in fact, "arrest" is really carried into "cure." Among these children impatience and desire of change do not break off the cure at the critical time as too often happens in adults; nor does the need of wage-earning or lack of funds return the half-cured case to the unhealthy conditions out of which the disease arose. Pulmonary tuberculosis is a disease of slow progress and still slower retrogression; it needs for its cure the years that are given to the treatment of surgical tuberculosis, and without them failure must follow, however successful in itself the form of treatment employed. Remember, therefore, at the outset that time is one of the essential elements in its treatment, and that this must be measured in years.

Now, what is the first essential in the treatment of active inflammation in any organ? You will answer, without hesitation, "Rest." This is as true of the lung as elsewhere, but how are we to apply it? For movement is the essence of the lung's function, and we cannot prevent it. We can, however, damp it down by reducing the need for oxygen through general bodily rest, and this in many cases suffices. Let the patient be put at rest, preferably in bed, as soon as the disease is diagnosed, or even before; it is well that he be impressed at the outset with the fact that he has an inflamed lung, and that the treatment for this is general bodily rest. Having seen to this, the next question that will be asked is, Should he go into a sanatorium?

Sanatorium Treatment.

The modern sanatorium lays itself out to employ all or most forms of treatment applicable to pulmonary tubercle, and the principles of sanatorium treatment are roughly the principles of the treatment of phthisis. They are, in the main, twofold: first, to build up the body's natural resistance to disease by general hygienic measures, and towards this open air, abundant daylight, and good feeding especially contribute; and secondly, to increase the specific resistance to tuberculosis by all known measures, of which the proper application of rest and exercise are the most important. Let us consider open air first, so as to clear the ground for the more important subject of rest and its corollary, exercise.

Open Air.

The real father of the open-air treatment of tuberculosis was George Boddington, who published his book *On the Treatment and Cure of Pulmonary Consumption* as long ago as 1840. In it he advised the unstinted use of open air in all weathers, and insisted especially on the value of cold air, both indoors and out—a revolutionary doctrine in those days. He advocated the provision of institutions for this outdoor treatment, and himself took a house for this purpose at Sutton Coldfield. But, surprising as it may seem, the value of fresh air in sickness appears to have been recognized long before this. Recently there has been unearthed in America a precious morsel from the writings of Benjamin Franklin about the year 1786; it runs as follows:

"It is recorded of Methusalem, who, being the longest liver, may be supposed to have best preserved his health, that he slept always in the open air; for when he had lived 500 years an angel said to him, 'Arise, Methusalem, and build thee an house, for thou shalt live yet 500 years longer.' But Methusalem answered and said, 'If I am to live but 500 years longer it is not worth while to build me a house . . . I will sleep in the air as I have been used to.' Physicians, after having for ages contended that the sick should not be indulged with fresh air, have at length discovered that it may do them good. It is therefore to be hoped that they may, in time, discover likewise that it is not hurtful to those who are in health; and that we may then be cured of the aerophobia that at present distresses weak minds, and makes them chuse to be stifled and poisoned, rather than leave open the window of a bedchamber, or put down the glass of a coach."

Open air in the treatment of phthisis should be as complete as possible, and the patient must be inured to it gradually. In particular, it is to be insisted that the patient be exposed to full daylight, unobstructed by glass. This is a very important element in open-air treatment, but sun, unless the air is cold, is safest avoided by patients with active lung disease. A prolonged sunning may lead to undesirable congestion of the tuberculous areas. The effect of open air, and especially of cold air breathed, seems to be a stimulation of metabolism, leading to increased appetite and well-being. Climate is secondary to open air, but is, I think, of more value than is sometimes admitted in this country. Tuberculous patients do best in a dry climate, and in this country are best sent east or south-east, according to the time of year. But with active disease the regime is more important than climate—even more important than open air—and this brings us back to rest and exercise, the first essentials in treatment.

Rest and Exercise.

Now although the house at Sutton Coldfield already referred to may be considered the prototype of the sanatorium as we know it, it must be noted that the importance of rest and exercise was recognized much later. Boddington's patients got their open air for the most part by walking and driving. But some twenty years later there was founded by Hermann Brehmer, at Görbersdorf in Germany, the first sanatorium on anything like modern lines. To Brehmer and his assistant Dettweiler belongs the credit of recognizing the importance of the regulation of rest and exercise in the treatment of pulmonary tuberculosis. Brehmer enjoined gentle exercise up sloping paths with rests at intervals. Dettweiler at a later stage became impressed with the need and value of rest above all things, and about 1880, at Falkenstein, initiated the famous *Liegekur*. His patients, febrile and afebrile alike, spent their time in reclining chairs in the *Liegehalle*. Dettweiler was also the founder of "absolute rest," called by him "cadaver rule," but in this country often referred to as "typhoid rest," for the control of troublesome fever. Since that day rest and exercise, pursued under open-air conditions, have formed the basis of sanatorium treatment the whole world over; only in the proportion and dosage of these has any difference of opinion obtained. There is universal agreement that cases decidedly febrile must be kept at rest as long as fever persists—beyond that point differences of opinion and practice exist. On the whole it may be said that Continental sanatoriums advocate rest, rather than the avoidance of exercise, while British institutions enforce less rest and make exercise a part of their routine.

* Delivered at King's College Hospital on March 8th, 1926.

The Control of Auto-inoculation.

Now where the Continental physician speaks of "the correct dosing of rest and exercise" (Dettweiler), here, thanks to spread of the ideas first initiated by Almroth Wright, we are apt to talk of "treatment by controlled auto-inoculation." For Wright has taught us the pleasant game of "antigen" and "antibody" on which the practice of vaccine therapy has been built up, and this has been of notable value in the rational application of rest and exercise in pulmonary tuberculosis. He showed us how the body's resisting power to chronic infections depends on a proper balance between them; how a suitable supply of bacterial products (antigen) is needed to produce an immunizing response (production of antibody), and how excessive and uncontrolled dosage may overcome antibody formation, with the result that symptoms appear and disease spreads; how, further, once the balance is upset it can only be recovered by control of the bacterial toxins let loose (control of auto-inoculation) by rest. For auto-inoculation may follow upon "all active and passive movements which affect the focus of infection, and upon all vascular changes which activate the lymph stream in such a focus." Now, at once it becomes clear that, for better or worse, our tuberculous patient is an unconscious vaccine therapist—nothing less, in fact, than an uncontrolled tuberculin factory whose products are at the mercy of his bodily activity. When he exercises he receives a dose of auto-tuberculin, and when he rests the dosage is reduced. Doubtless other tissue poisons and toxins from other bacteria also come into play, but these may here be neglected. Thus the treatment of tuberculosis demands above all some knowledge of the action of tuberculin and of the means whereby it can be turned to therapeutic use. This knowledge will be necessary, not only in the control of rest and exercise and the understanding of the patient's symptoms, but also in the use of many drugs, in addition to tuberculin itself, used in the treatment of pulmonary tuberculosis.

The Action of Tuberculin and Auto-tuberculin.

Now all vaccine therapists know the stages of an "immune reaction"—how dosage with antigen is followed by a "negative phase," during which resistance to disease is lowered, and later a "positive phase" with improvement; and how, also, if the dosage is excessive the negative phase may persist, and no positive phase of raised immunity follow. If an effective dose of tuberculin is given to a tuberculous patient it is followed, after an interval of eight to twenty-four hours, by a "reaction" corresponding to the negative phase. At the point of injection there may be a "local reaction," with redness and swelling; a "general reaction" is shown by fever, malaise, and perhaps headache; and a "focal reaction" occurs in every active tuberculous focus. It is this focal reaction which especially concerns us. Each area of disease becomes flooded with blood, and this leads to an increase of physical signs, and of symptoms such as increased cough and sputum. If the dose has not been excessive for the type of case all these symptoms may quickly clear and a positive phase of immunity may follow. If, however, the focal reaction has been severe, and has occurred in areas of very active disease, other phenomena may follow. Further toxins and bacilli washed out may lead to further "secondary" reactions, both general and focal, with corresponding prolongation of fever and illness, and these may continue and increase owing to further spread of disease and increased sensitiveness to tuberculin. This gives us the picture of autotoxic tuberculosis brought about by neglect of treatment.

Now if instead, the dose of tuberculin has been moderate and followed by a mild reaction, it will be found that a period of increased "tolerance" to tuberculin ensues. During this period a larger dose will be tolerated, and by giving a gradually increasing dose at the best interval, which is found to be about twice weekly, we can establish tolerance to very large doses. The same can be accomplished with auto-tuberculin on a system of graduated exercise. If, however, instead of raising the dose we continue the same small dose, or if we seriously overdose our patient, the opposite condition to tolerance may sometimes

be brought about—namely, a hypersensitiveness to tuberculin.

Now let us apply this to a case of pulmonary tuberculosis. If he is ill and febrile we know he is overdosed with tuberculin from the diseased lungs. He is suffering with "general reactions," shown in fever and symptoms, and at the same time with "focal reactions," leading to congestion of the tuberculous areas, further washing out of toxins and bacilli, leading to further "secondary" reactions, and to increased activity and spread of disease. This is a vicious circle which can only be broken by cutting down the supply of auto-tuberculin. This is achieved by complete bodily rest—the demands for oxygen are thereby reduced, and lung movements and lung circulation are damped down. After a time the auto-tuberculin reactions die down and the patient becomes afebrile and free from symptoms. But disease is still active—get the patient up again and fever again appears.

After an interval for the tissues to recover their lost balance it will be found possible by a graduated regime to bring the patient back stage by stage to active movements without any fever resulting and even with a steady-*ing* of temperature. With each step forward it may be found that the temperature shows a slight rise, or an increase of the diurnal fluctuation, but these after a short time again subside. These are evidences of "immune responses" to auto-tuberculin accompanied by a steady rise of tolerance. Finally the patient, with disease which is far from being arrested, may yet be following a vigorous regime without any untoward symptoms—thanks to this tolerance. But if tolerance is upset at any point by too rapid rise of dosage violent reactions may occur and a period of rest be again required.

This means of establishing tolerance has been pushed further by Paterson and others into a system of "graduated labour," whereby considerable physical exertions are undergone towards the end of treatment. The advocates of this have spoken of the "high tide of immunity" thereby achieved, but high tolerance of tuberculin is probably something quite other than increased immunity to tuberculosis, and recent evidence seems to show that the ultimate results of graduated labour are inferior to those obtained by systems where a more resting regime is followed.

Ought Auto-inoculation to be Employed?

And now, having seen that we can, once autotoxic symptoms have been controlled by rest, in many cases get our patients up again with disease still active, we may inquire whether we ought to do so. I may remark at once that, owing to lack of beds for pulmonary tuberculosis among the hospital class, and of nursing accommodation in sanatoriums, the establishment of tolerance at an early stage has become almost a routine of practice in this country, so I am putting to you no hypothetical case. The answer to the question must depend to a large extent on the type of disease from which our patient is suffering. In disease of chronic, fibroid, "proliferative," or "productive" type, mild reactions and a full blood supply seem in many cases to promote the healing of disease, though even in such cases it may be argued that increased movement may tend to spread the fibrosis and prevent the proper encapsulation of the tuberculous areas. But in cases of acute, caseous, or "exudative" type a very different result must be anticipated. Both reactions and congestion may lead to softening of caseous areas, and though in the neck glands this may be of little consequence or even convenient, in the lungs it is a serious matter, for it leads to cavitation. Now tolerance may prevent reactions during exercise, but yet all exercise means flushing of the lungs with blood, for the pulmonary circuit must hand on all blood which the systemic circulation puts into motion. Moreover, the lung movement, a serious bar to healing, must also increase. Therefore no patient with caseous areas of any extent should exercise till disease is fully quiescent; and since most cases of tuberculosis are of mixed type and contain some areas of caseous disease, exercise should be regarded as a somewhat dangerous measure in pulmonary tuberculosis until all evidence of activity is past.

Febrile Cases.

The patient should be put at rest as soon as the disease is suspected or diagnosed. If there is fever, rest in bed must be carried on, under open-air conditions, until all fever has gone, and as long after as symptoms and signs suggest that disease may still be active—for activity is not limited to the period of fever. Where fever continues in spite of rest in bed, this must be continued in the hope that eventually it will subside, which it may do after even three or four months or more of waiting. In such cases more complete rest must be aimed at—what is known as “typhoid rest” tried, talking forbidden, and possibly some means of “splinting” the inflamed lung attempted. The possible need of collapsing the lung in such a case by artificial pneumothorax must not be neglected till too late. As long as fever persists rest is the one essential of treatment, and such a patient may be better nursed in his own home, if conditions are suitable, than in a sanatorium. Sanatoriums do not provide nursing accommodation for many febrile cases, so the febrile stage is best arranged elsewhere. The same also applies to the hospital class; if these could receive bed treatment in their own homes, during the early stages, as has been so successfully done under the so-called “class method” in Boston and Montreal, the institutions now provided could be put to their proper purpose—namely, the establishment of tolerance when disease has become quiescent, not, as now, while it is still active. Many cases end fatally where, if rest could have been carried on for a year or more, recovery might have ensued. Six or more months’ rest is not a bit too much for a case of serious type.

Afebrile Cases.

Cases with little or no fever will require less in the way of strict rest, but at the outset a period of bed, and later bed and couch or lean-chair, will be needed. The symptoms which bring them under observation are an evidence of active disease, and active disease requires rest. There will come a time with these patients, however—and also, though later, in febrile cases that progress—when the question of movement and exercise will arise. At most Continental centres for the treatment of tuberculosis exercise is for the most part considered a mere necessary return to normal life and not as an element in treatment. I think this is the safest view to take of it, but with a somewhat liberal interpretation. When disease is arrested the patient should be got slowly but steadily back to normal exertions, and five to eight or ten miles’ walking exercise daily is not too much to end up with. But this must be slowly and steadily achieved, with an eye on the temperature chart; any rises of temperature must be met by a return to a more resting regime. It is especially during this stage that the sanatorium is of unique value, providing as it does the skill of a physician specially trained in this difficult work. At the same time that exercise is being steadily pushed to these moderate heights the patient must have some hours of complete rest on couch or lean-chair during the day, and for some part of this time should relax his muscles and do nothing, or sleep if he will. In British sanatoriums some two hours’ compulsory rest is usual, one hour of which is before lunch. On the Continent at least seven or eight hours’ daily rest is the rule. I think myself that in this country we do not carry rest far enough, and the rest between lunch and tea invariably practised abroad might be adopted here with advantage.

I have been careful to utter a warning about the possible dangers of exercise, even graduated exercise given therapeutically, in cases of pulmonary tuberculosis not fully quiescent. Nevertheless I have admitted that graduated exercise, or “controlled auto-inoculation,” is a method of treatment that can be pursued with advantage in certain quiet types of case. But “immuno responses” may be obtained by other means than exercise, and these other means must now be considered—first, tuberculin treatment, and secondly, treatment by certain drugs which produce reactions.

Tuberculin Treatment.

I have already considered the effect of a tuberculin injection—how a large dose may lead to severe reactions,

local, general, and focal, and may, like auto-tuberculin, upset immunity, and start the patient in a vicious circle of reactions with serious results. I have also shown how, with a step-like increase of dose, the patient may receive a desirable “immuno response” to each dose, and establish a growing tolerance. For localized tuberculosis, as in surgical cases, where there is little or no auto-inoculation, tuberculin can be used in small doses, repeated with the same response every two weeks, by which time tolerance will have dropped again. But in autotoxic tuberculosis, as in lung cases, where inoculation with auto-tuberculin already occurs, it is found better to raise the dosage steadily at a shorter interval and so establish tolerance. Otherwise it is impossible to find and keep the level of effective dosage, since this is interfered with by irregular additions of auto-tuberculin. Doses are started in the neighbourhood of a millionth to 100,000th of a cubic centimetre, and rise steadily, by geometric progression, to a final dose of 1 c.c.m. Here again, as in “graduated labour,” we establish high tolerance to tuberculin, but we must not delude ourselves into the belief that this is the same as high immunity to tuberculosis. It is more probable that such good as arises from tuberculin treatment depends on the short immune response to each dose, rather than on any cumulative effect. There is, I think, no doubt that a well applied course of tuberculin does good in suitable cases, but the treatment has gone out of fashion here largely on account of the trouble involved to both doctor and patient. If it had been the remarkable remedy some have held this would certainly not have happened. If it is used, my advice is that large reactions should be avoided—that getting a minimum but definite response to each dose should be aimed at. Any marked reaction must be met by rest and the return to a lower dose at the next injection. But too timorous an advance is as bad in its effect as overboldness. The treatment is not suitable for febrile cases, nor for “exudative” types of disease. It is useful in those quiet chronic types for which graduated exercise may be employed with impunity or even with advantage. There are also cases of mild fever hanging fire where a minute dose of tuberculin (or auto-tuberculin) may sometimes start the body’s delayed effort at immunity.

The tuberculins on the market are very numerous, but their actions are very similar; the best known are Koch’s three preparations—old tuberculin, new tuberculin or T.R., and bacillus emulsion or B.E. Of recent years many preparations of split tubercle bacillus have appeared, among which may be mentioned Dreyer’s “defatted antigen,” which was introduced in 1923. My experience with this preparation is that it may do good in a certain class of case, just as do other tuberculins. It is no cure for tuberculosis.

Drugs causing Reactions.

I may now turn from tuberculins to certain drugs which cause “reactions” in patients suffering with active pulmonary tuberculosis. How these reactions are produced is not yet clear, but for some of the preparations recently introduced it is claimed that the tubercle bacillus is attacked and destroyed *in situ*. It has long been known to those treating cases of pulmonary tuberculosis that potassium iodide, arsenic, creosote, and some other drugs may cause “focal” reactions in certain cases, but it has been to the salts of the heavy metals that attention has been directed of recent years—those of copper and gold especially, and to a less extent of nickel and cobalt.

Copper.—Copper salts were used in very early days, and their use was revived in France by the Lutons, father and son, about 1880. They observed that they possessed a specific affinity for tuberculous tissues, just as did Ellis more recently with his “picric-brass paste,” and given internally they found that focal and general reactions followed. They gave for the most part copper acetate, and later workers have used copper chloride, a dimethyl glycol copper, and other preparations. Begun at first by the mouth and subcutaneously, they were finally employed intravenously. These experiments seemed to bring out two important facts: (1) a selective action possessed by copper for tuberculous tissues; (2) the apparent ability to get copper into contact with tuberculous tissues by general administration, and to cause reactions. These reactions

774 MAY 1, 1926]

were followed by improvement in some cases, but in others by none, and this no doubt depended on the class of case treated. Feldt of Frankfurt, working with gold salts, claimed that reactions following the use of these were, on the contrary, always beneficial.

Gold.—Gold therapy may be said to date from Koch, who in 1880 discovered that gold salts, especially the cyanides, possessed an inhibitory action on the growth of the tubercle bacillus *in vitro*. Gold potassium cyanide had been recommended for internal use in pulmonary tuberculosis by Chrestien as long as sixty years ago, and its use was revived about the year 1913. Later, about 1917, a gold-cancharidin preparation called "aurokantan" was introduced by Feldt, and this gave place to a body called "krysolgan," which was given intravenously in 10 per cent. solution. Reactions followed the use of these preparations and were said to lead to improvement. Feldt claimed that krysolgan "increases the production of normal and specific antibodies, renders the tubercle bacillus harmless, and that in doses which for the remaining body cells are not only harmless but exert a stimulating influence." Lydia de Witt of Chicago, however, testing it on tuberculous guinea-pigs, found that life was not prolonged and disease not checked. From an analysis of the organs of healthy and tuberculous animals so treated she concludes "that gold has shown no specific affinity for tuberculous tissues." Moreover, she found that tubercles flourished in organs containing large amounts of the metal. In 1924 Moellgaard of Copenhagen published a preparation named "sanoerysin," a double thio-sulphate of gold and sodium, which, he claimed, would diffuse through the non-vascular tuberculous tissues, penetrate the fatty capsule of the bacillus, and attack it *in situ*. Intravenous injections of this body in 4.5 to 5 per cent. solution lead to violent reactions, often with erythema and albuminuria, and in some cases "shock" symptoms, and these have been ascribed, as they may well be in part, to the mobilization of auto-tuberculin. A serum has been used with the hope of neutralizing these toxic effects, but it appears to be of doubtful utility. Various results, some good and some bad, have so far been attained, and the method is still under trial. Whether we are here dealing with a true chemotherapy, or only a treatment by reactions, still remains. I think, to be proved. It has, of course, always been seen that the difficulty which would be met, if chemotherapy could ever be applied to tuberculosis, would be the large and perhaps fatal reactions caused by the release of auto-tuberculin.

Before leaving the subject of treatment by reactions it will be well to mention one or two other subsidiary forms of treatment which probably act in similar manner and have had their advocates. The first of these was that by nascent iodine, which is, I think, no longer used. Then there is the sodium morrhuate treatment, introduced by Leonard Rogers, the substance injected being a sodium salt of the unsaturated fatty acids of cod-liver oil after extraction by ether. Lastly, there is colloidal calcium. It is curious that these substances should produce reactions very similar to those produced by tuberculin, but so it is, and in certain cases, as happens with other methods of auto-inoculation, a certain measure of improvement follows. Whether with any of these measures the results justify the means, or whether they present any definite advantage over the "controlled auto-inoculation" produced by suitable rest and exercise, is a question difficult to answer. Certain it is that no striking results, unobtainable by other means, have ever been demonstrated.

It will be clear from the consideration of the action of tuberculin or auto-tuberculin, that the treatment by reactions, however they are induced, is a treatment which must be pursued with caution, and not applied to cases of exudative or caseous type. Only it may be said, that if a true chemotherapy be proved for gold or others of the heavy metals, then some risks may, perhaps, be justifiably run during the destruction of bacilli in areas of active disease. But in a disease so treatable as pulmonary tuberculosis, in all but its later stages, there is a strict limit to this.

Excessive Auto-inoculation.

I will now turn away from the cases—mostly afebrile, or at least ambulant febrile—where artificial auto-inoculation might be considered, to the directly opposite condition where auto-inoculation is excessive, whether from the amount or type of disease, and must be controlled if the patient is to live. This will be the febrile case with disease progressing in spite of bodily rest, and with this I will consider the case where disease, whether febrile or not, has reached a stage where mechanical factors prevent healing. It will be found that a proportion of such cases are wholly or largely one-sided, and among these collapse of the lung by artificial pneumothorax or other means has been attended with notable success.

Artificial Pneumothorax or Lung Collapse Treatment.

As long ago as 1821—that is, as soon as the elastic recoil of the lung was an established fact—James Carson of Liverpool had recognized how serious a bar to healing were the pool had recognized how serious a bar to healing were the elasticity, condition of extension, and constant movement of the lungs, and on these grounds urged lung collapse as a method of treatment. In absence of the lung he noted how "the sides of the abscess are prevented from falling into a salutary contact, not by the matter which lodges between them, but by the powerful elasticity and retraction of the surrounding substance." By collapse of the lung, on the other hand, "the diseased part would be placed in a quiescent state, receiving little or no disturbance from the movement of respiration, which would be performed solely by the other lung, and the divided surfaces would be brought into close contact by the same resilient power which before had kept them asunder." With regard to "consumption," he remarked: "in those cases in which the disease is placed in one of the lungs only, the remedy would appear to be simple, safe, and complete." He also foresaw its value in pulmonary haemorrhage. Later on in the century the occasional improvement following spontaneous pneumothorax was noted by various observers, but pneumothorax as a form of treatment may be said to have seriously started with the publication of cases by Forlanini in 1894 and 1895. Now it is recognized as a most valuable measure all the world over. The cases for which it is suitable fall into two categories: (1) cases of active disease which strict recumbency has failed to arrest, and where more complete rest of the lung is needed, and (2) cases where cavitation and extensive disease have rendered healing impossible in the extended lung. To these may be added recurrent severe haemoptysis. Disease must be the main, one-sided, or if disease is present in the better lung it must be of quiet type and not too extensive. Much experience is needed to decide what is a suitable case, but in a doubtful case an artificial pneumothorax can be tried and its effects watched.

As a rule, under pneumothorax treatment the functioning lung improves rather than deteriorates. This might be almost expected, for by collapsing the bad lung we remove the source of auto-inoculation whereby severe focal reactions, tending to increased activity and spread of disease, were occurring in all tuberculous foci in the better lung.

Artificial pneumothorax is brought about by the injection of air or nitrogen gas into the pleural cavity, and for this all that is needed is a gas bottle, a pressure bottle containing liquid, a water manometer, rubber tubing connecting these, and continued through a cotton-wool filter to a suitable needle. The needle is passed through the chest wall under proper precautions, and its arrival in a free pleural space recorded by the manometer. As soon as it is clear that the needle end is in the pleural cavity gas is allowed to enter. The main risks during the operation are those of gas embolism if a vein is entered, or "pleural shock," a reflex disturbance which is occasionally countered. Gas is given every few days at first, in quantities varying from 300 or 400 to 800 c.cm., and full collapse of the lung becomes a small solid mass against the spine, and the heart and mediastinum are carried over towards the opposite side. This displacement must not go too far, and is controlled by the gas pressure. A lung full of disease collapses but slowly. After the first few fillings there is often an increase of fever, and as the lung collapses

its contents are squeezed out and appear as an increase of sputum. But in a short time, in a successful case, the sputum again diminishes or disappears, the fever wanes, and the patient rapidly reaches a condition of "clinical recovery." But the diseased lung, though removed from view and no longer, thanks to the stagnation of its lymph and blood supply, providing poisons, will need a long period to reach "anatomical recovery." This takes place by an active fibrosis throughout the organ, and treatment can generally be given up after some three or four years. The lung's re-expansion will then depend on the extent of disease, and is often pretty complete unless it is bound down by a thickened pleura resulting from pleural attacks during treatment. Pleurisy is a common complication of artificial pneumothorax, and attacks, generally in a slight form, fully 50 per cent. of cases at some time during treatment.

The main trouble in pneumothorax treatment is the very common presence of pleural adhesions, which tend to limit collapse. Sometimes only a few bands are present, which stretch or break under treatment. But in many cases part of the lung, often the most diseased part, is held out to the chest wall, and we have attained only a partial pneumothorax. This may, in some cases, suffice to arrest symptoms and eventually ensure a cure. But often the pneumothorax is thereby rendered useless. In a few of these cases adhesions holding the lung may be artificially divided, whether by thoracoscope and cautery or by open operation, but very few are suitable for these measures. In a proportion of cases, also, otherwise suitable for pneumothorax treatment, total adhesion of the pleural surfaces is found to exist.

Surgical Measures.

For those cases where pneumothorax treatment has failed owing to adhesions, there remains still the possibility that the diseased lung may be collapsed by suitable surgical measures. Many operations have been devised and have been more or less successful, but the operation which holds the field at the present time is that known as extrapleural thoracoplasty. Thoracoplastic operations with a view to collapsing cavities date from de Cereville of Lausanne in 1885, but their use as a substitute for failed pneumothorax was first pursued by Brauer and Friedrich about 1907. The modern form of operation—a paravertebral resection of ribs—is especially associated with the names of Sauerbruch, Wilms, Brauer, and to a less extent of Saugman. Portions of all the ribs, from the first to the tenth or eleventh inclusive, are resected through an incision running down the back over their angles. The aim is to obtain a satisfactory collapse of the hemithorax, and for this it is necessary to cut the ribs back to the transverse vertebral process, and especially to include the first rib so that the ribs may fall like the handle of a bucket. The shoulder girdle remains intact, and hence there is little deformity. The operation is done in one or two stages, according to the condition of the patient, the lower part first. Sometimes the operation is preceded by phrenicotomy to paralyse the diaphragm; the main danger is aspiration pneumonia, and this is thought to help in its avoidance. The results of these operations in skilled hands have been highly encouraging, but they can only be performed with advantage in carefully selected cases. In the main, cases suitable for pneumothorax are suitable for thoracoplasty, but the indications must be much more rigidly drawn. The other lung must be more severely scrutinized—it is all too likely to break down under a surgical operation. Also thoracoplasty is more suitable for the second class of case mentioned under indications—extensive chronic disease—than in the first class, where lung rest is desired in a case of active disease. It is claimed from large statistics that 33.8 per cent. of advanced disease are cured, and 24.4 per cent. improved as the result of thoracoplasty—no small success when the class of material is considered.

Principles of Treatment in certain Important Complications and Symptoms.

Haemoptysis is, to the patient, a very terrifying experience, and the first point is to allay anxiety and instil

confidence, since thus cardiac excitement is stilled, and restlessness mitigated. For this morphine, the usual panacea, should be avoided, especially if the haemoptysis is large, or at most given in small doses. Better is a large dose (30 to 60 grains) of sodium bromide. The danger of haemoptysis lies more in the retention of blood in the lungs, leading to pneumonia or further spread of tuberculosis, than in the quantity of blood expectorated; consequently it is of the utmost importance that the cough reflex be not abolished by drugs, such as morphine in large doses. The patient is best propped in the semi-upright position, so that coughing is easy, and told to restrain too violent or needless cough. Speaking should be avoided. Aspiration of blood and secretion will probably do no harm unless too long retained, and this is not likely to happen if the cough reflex is intact, or only slightly dulled, if too violent, by quite small doses of heroin or codeine.

To control the haemoptysis we should have three things in mind: (a) reducing the pulmonary blood flow; (b) increasing coagulability of blood; (c) contraction of the bleeding vessel.

(a) The first of these is best achieved by damping down the systemic circulation by rest, a cool surface, and avoidance of cardiac excitement. Vaso-dilators and vaso-constrictors should be avoided, for both increase pulmonary blood flow. Cardiac depressants, such as the depressant expectorants, are unpleasant remedies; but pituitrin, which is said to act as a depressant to the right heart only, may be used and has proved effective. In large haemorrhages binding the limbs and cupping the abdomen will hold up blood from the lungs for a period.

(b) Increased coagulability of the blood is best attained by "salt action," whereby tissue fluids carrying thrombokinase are drawn into the blood vessels. Sodium chloride may be given intravenously in hypertonic solution (5 c.cm. of 10 per cent. solution), or by the mouth—a teaspoonful in half a tumblerful of water; some of this may be replaced by sodium bromide, which has the same action. Binding the limbs probably adds thrombokinase to the blood when the pressure is released. These effects, though valuable, are apt to pass off quickly, though their application can be repeated. Other remedies which may have more lasting effects on blood clotting are calcium, given intravenously or intramuscularly, gelatin, horse serum, or such preparations as haemoplastin, coagulen, etc., but the action of all of them proves very doubtful in practice.

(c) Contraction of the bleeding vessel we can influence little or not at all. If the bleeding area is known an icebag may be applied; ice must not be given to suck, since this has been found to dilate the pulmonary vessels. Sandbags and strapping have been largely abandoned owing to the fear of retention of blood clots. Lastly, the bleeding-point may in many cases be closed by pneumothorax. In arranging the after-treatment it is useful to remember that it takes twenty-four to forty-eight hours for a vessel thrombus to fix, and many days or weeks for organization of the clot.

Fever.—Fever we must regard as evidence of toxæmia, to be treated by the reduction, by all means in our power, of auto-inoculation. Only in some subpyrexial cases it seems as if a mere hypersensitiveness exists, to be controlled in some cases by a careful increase of auto-inoculation or a minute dose of tuberculin. The use of antipyretics, especially of pyramidon and ergogenin in small doses, has been extolled by some in febrile cases of pulmonary tuberculosis. I do not think myself that by their use we break any vicious circle, as is claimed, nor improve the patient's well-being in any way.

Cough.—Cough is in some cases a troublesome symptom, in that it disturbs healing of the lung and increases auto-inoculation. The patient must learn to restrain it, and with practice may do much. Often it is easier if rendered looser, especially by that useful drug ammonium chloride. Opium preparations should be postponed as long as possible—they soon upset general well-being. Lozenges containing demulcents, as liquorice and perhaps some menthol, will often suffice, or for some patients an occasional inhalation containing menthol, eucalypt, and chloroform.

THE TREATMENT OF SPASTIC PARALYSIS IN CHILDREN.

BY

H. A. T. FAIRBANK, D.S.O., M.S., F.R.C.S.,
SENIOR ORTHOPAEDIC SURGEON, KING'S COLLEGE HOSPITAL; SURGEON,
HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

It is generally agreed that a spastic condition of one or more limbs of a child can result from one of the three following causes: (1) prenatal damage to the brain, (2) intracranial haemorrhage at birth, and (3) inflammatory injury to the brain after birth—for example, poliomyelitis or syphilis. It is the relative frequency of the first two that is in dispute.

James Collier¹ has done much to convince medical opinion—including, we believe, the majority of the neurologists—that the damage in most cases is done before birth. He attributes the lesion to "primary neuronic degeneration." Some physicians, notably Hector Cameron,² are still unconvinced, and regard intracranial haemorrhage as being a common cause of this condition.

Fortunately this question is not of practical importance to the orthopaedic surgeon, as he is concerned with the results of the lesion rather than with the lesion itself. It is, however, important that he should be satisfied that the lesion is not progressive. In some non-syphilitic cases—both pre- and post-natal (Collier)—as well as in those in which syphilis is the cause, the case may become progressively worse; this is very rare in my experience. The surgeon should, however, exclude these cases by a careful history and the Wassermann reaction before considering surgical treatment. If we accept Collier's conclusions, and I think we must, we must necessarily doubt the possibility of doing any good by a decompression operation as practised by Sharpe.³ I have no experience of this method of treatment; it did not seem to me called for in any of my cases. We may take it, therefore, that in the majority of cases the lesion is not a progressive one, but, on the contrary, any case will in all probability tend to improve. The surgeon's business is to see whether he cannot hasten the improvement, or, indeed, make possible an improvement which otherwise would be out of the question. What, then, are the chief effects of the lesion or lesions, and how do these influence the question of surgical treatment?

SYMPTOMS.

Mental.—All grades of mental defect are met with: there may be gross idiocy or what appears to be normal intellect. The mental affection seems to go more or less hand in hand with the severity of the limb affections in the majority of cases. It is uncommon to see a case which is not more emotional than the average, but occasionally the child is quite normal. On the other hand, mental deficiency associated with very marked spasm or uncontrolled movements may even prevent the child from sitting up, while walking is, of course, impossible. Such a case is unsuitable for operative treatment, and should be re-examined after a lapse of from six to twelve months. There is no doubt, as Cameron and O-man⁴ have insisted, that most cases show a marked improvement, both mental and physical, as they grow older. It is noteworthy that every surgeon who advocates a particular line of surgical treatment, whatever this may be, states that the mental condition improves to a decided degree after his operations. Any treatment which lessens the difficulty in walking will undoubtedly lead to mental improvement, and for two reasons: the less the difficulty in walking the more can the child get about, mix with other children, see things for himself, and thus undergo normal unconscious education; while in addition his brain is freer to receive impressions instead of being concerned entirely with trying to move one leg in front of the other. Mental deficiency should not be considered by itself as a contraindication to operative treatment, provided there is a reasonable chance of this enabling such an imbecile to walk.

Fits.—Epilepsy is more commonly associated with hemiplegia than with the other forms of spastic paralysis (Batten⁵). If the fits are recurring with any frequency,

operative treatment should be delayed, but if no fit has occurred for a year or more a history of such is no bar to operative treatment. It is our custom to give bromides in all cases for a few days before and after operation, however small this may be, and whether fits have occurred or not.

Paralysis.—The paralysis is for the most part spastic in character, but not always or entirely so. Certain muscles or groups of muscles may, indeed, be flaccid and partially or completely paralysed. That is not uncommonly seen in the arm. Great weakness of a muscle group can undoubtedly result from overstretching caused by the spasm of their so-called opponents, but in the forearm both opposing groups may be equally affected by flaccid paralysis in a case in which the leg or legs show a typical spastic condition. Nothing can be done for this flaccid hypotonia. The type of case here referred to is quite distinct from the "atonic" group of diplegias with general hypotonia of the limbs and which usually exhibit grave mental defects (Batten⁶). It is the spasm and deformity resulting from the cerebral lesion, whatever its nature, with which the surgeon has to deal. This spasm is increased by handling the limb, and more importantly by any attempt at voluntary movement on the part of the patient. There is yet another factor which may play a part in the child's disability. While in most cases it is obvious that the spasm—arising from the failure to accomplish the desired movement—transmitted to the limbs to produce movements—responsible for the failure to accomplish the desired movements, in others there seems to be a lack of power to originate the necessary impulses. This again is more frequently seen in the upper limb, and is most marked in those with the greatest amount of mental affection, but by no means confined to them. It is not always easy to estimate how much of the imperfect function of a limb should be attributed to spasm of certain muscles and how much to a want of voluntary initiation of impulses which should be transmitted to their opponents. A correct estimation of these various factors in any given case is of great importance in deciding the prognosis, and therefore has a distinct bearing on treatment.

Involuntary Movements.—There may be involuntary movements which interfere more or less with the use of the affected limb. These may be of the rhythmic athetoid type developing some time after birth, of the more explosive and erratic choreic type, or they may belong to the so-called "porverse movement" group. It is not always easy to classify a particular involuntary movement. For instance, a case was recently seen with a typical monoplegia of one leg with only a mild degree of mental affection. The child had the typical spastic equinus, but when she began to walk the tibial muscles took complete charge of the foot till it rested on the outer border. After a few moments, during which the child stood with a self-conscious expression on her face, this spasm passed off and she was able to continue her progress with an equinus deformity only. Handling the foot would sometimes bring on this inversion spasm. The temporary nature of the spasm was the peculiar feature of the case. The presence of athetoid or other involuntary movements is generally considered to be an absolute contraindication to operative treatment. This is unquestionably sound in the vast majority of the cases displaying these complications, but occasionally in carefully selected cases operation is justifiable and is followed by definite improvement in the use of the affected limb. This was so in the case referred to above, where the varus spasm was completely cured by tenotomies.

DEFORMITIES.

The deformities which arise are the result of spasm of the stronger groups of muscles (for example, the gastrocnemius and soleus), or of those which act at a mechanical disadvantage (for example, hamstrings), aided in some cases by gravity (for example, drop-foot, etc.). It should be remembered, however, that in the ordinary case all the muscles of the affected limb are a potential source of spastic deformity, and that, as Stoffe⁷ has pointed out, a spastic deformity in any direction can be produced by fixing the limb in a particular position for a sufficient

time. This is a most important point to remember in the after-treatment of cases treated by operation. I have more than once seen spastic calcaneus result from injudicious after-treatment, where the tendo Achillis has been divided or lengthened, while similar overcorrection of other deformities has been met with occasionally. Once started, the want of balance between opposing groups of muscles tends to increase, the muscles which gain the battle and deform the limb tend to become stronger, while their stretched opponents tend to become weaker. At first these deformities can be fully overcorrected in a few moments by firm manual pressure—that is, the deformity is entirely due to spasm; but sooner or later a secondary contracture (anatomical shortening) occurs, so that the deformity can only be partially corrected by manual force. The time this secondary contracture takes to develop varies considerably: while in some it is surprisingly late in development, in others, for no apparent reason, it develops much earlier. For instance, an equinus may be accompanied by real contracture requiring lengthening of the tendo Achillis at the age of 3 years, whereas another case may reach the age of 6 and still the deformity be due to spasm only. With the anatomical contracture of the muscle also occur accommodative changes in the ligaments, fasciae, etc. In some cases, however, with an atypical deformity, the excessive spasm of the particular group of muscles involved would appear to result from an unusual distribution of the lesion. Otherwise how can we account for the occasional occurrence of internal rotation of the whole leg?

The usual deformities met with are the following. In the arm, flexion of the elbow, pronation of the forearm, flexion and ulnar deviation of the wrist, and flexion of the fingers and thumb. In the leg we see adduction of the thigh, flexion of the knee, and drop-foot. In addition a valgoid deformity is common, especially after correction of equinus, and in a few—particularly, I think, hemiplegias—internal rotation of the whole leg is seen. Less commonly is there a varus tendency which may or may not be corrected by correction of the drop-foot. Only once have I met with a primary bilateral calcaneus deformity, though this has been seen on a few occasions as a result of overcorrection of the equinus. The hips may show a flexion deformity, the extensors being weak and the child having great difficulty in maintaining the erect posture when standing.

I do not propose to discuss the difficult and much-disputed question of the nervous mechanism on which muscular tone depends, nor the neurological problems involved in the production of the spastic condition of the limbs. Reference must be made, however, to the experimental work of Hunter and Royle,⁴ as a new method of treatment was the outcome of it. To put it briefly, these workers came to the conclusion that, in part at any rate, muscular tone is under the control of the sympathetic system, and on this they founded a method of operative attack for spastic cases—namely, ramisection or division of the grey rami in the cervical and lumbar regions. The conclusions they drew from their experiments have met with severe criticism at the hands of the neurologists, while the results of the operation of ramisection for these cases have been universally disappointing both in this and other countries (Bankart,⁵ Lewin, etc.).

TREATMENT.

It may be said at once that I agree with those (Bankart, for instance) who say that massage, commonly ordered for prolonged periods at great expense, is absolutely valueless. Apart from operation, if such be necessary or advisable, treatment should be directed towards patient daily training in the movements which are performed with the greatest difficulty, and gentle but firm manipulation to stretch the muscles chiefly affected by spasm: this corrects the deformity and thus prevents secondary anatomical contractures. It is often surprising how much a child will improve under the above treatment. It is well known that these children learn to sit up later than the normal; they stand and walk late; they have to contend with difficulties unknown to the normal child. It may be that a patient never walks until by operation the chief obstacles to locomotion are removed. But whether operation is necessary

or not, in all but the less severe cases an immenso amount of patience is required to make the child walk reasonably well. To return to the question of massage, while condemning its general and prolonged use as being waste of money, it must be admitted that it may be useful under certain conditions. For instance, applied to weak muscles after an operation designed to weaken their opponents, it is rational; while in hemiplegias, where an annoying amount of shortening of the affected leg may be found, massage to improve the nutrition of the limb, and thus limit the amount of increase of the deformity, is again rational. In both cases, however, massage falls far short of systematic exercises in usefulness. Fixation of the deformed limb in plaster-of-Paris is not advisable; in fact, plaster is not of much use in these cases except occasionally after operations, particularly those on the nerves or muscles of the forearm.

The aim of operative treatment is to reduce the excessive spasm in certain groups of muscles, and thus to correct deformity and restore as far as possible the balance of the opposing groups. We cannot make a spastic limb normal, but we can improve, often to an enormous extent, the patient's control over the limb in selected cases.

Three years is a suitable age for operation, though in the case of the upper limb it is probably wiser to wait until six years, as the co-operation of the child in the after-treatment is necessary. The patients must be able to sit up alone, and exhibit a definite desire to walk. If they can sit alone they almost invariably manage to put one leg in front of the other alternately when supported, however severe the adductor spasm may be. If the child cannot sit it is useless to try and make it walk, and operation should be delayed.

What operative methods are at our disposal? Only two methods are worth discussing in detail: (1) operations on the tendons and muscles themselves, and (2) excision of some of the motor nerve fibres passing to the spastic muscles. Förster's¹⁰ operation of division of the posterior spinal roots—that is, division of the afferent paths to the cord—has been given up for this class of case, even, I believe, by Professor Förster himself. It is a difficult operation which gave many disappointing and some fatal results. I have already referred to Royle's operation, or ramisection. My small experience of the results of this operation agrees with that of other surgeons; as a method of treatment in the cases under consideration it is unfortunately useless.

Operations on Tendons and Muscles.

The operations on the tendons and muscles include tenotomies and myotomies, tendon lengthenings, excision of portions of tendon and muscle, and tendon transplantations. The last has been used more for the upper limb, but in the few cases in which it was tried it has not been successful in my hands, possibly for the reasons which are given in discussing the treatment of the arm. Simple tenotomies and myotomies constitute the oldest method of treatment and are still used extensively by some surgeons. The method is of the greatest service in many cases, particularly an open tendon lengthening; when there is real anatomical contracture of a muscle an operation on the tendon or muscle is often imperative. Operation on the afferent paths (Stoffel's operation) is the other method which has proved of real value. In common with several other surgeons in this country, I am indebted to Mr. Blundell Bankart for my introduction to this method. Stoffel and others have done an immense amount of work in mapping out the various recognizable nerve bundles composing the main nerves of the limbs and in tracing them to their destinations. In some cases a knowledge of the arrangement of the nerve bundles in a main nerve is not necessary, as the branches after they have left the parent trunk are more easily attacked; while in others—the median, for example—a knowledge of the minute anatomy of the larger nerves is of distinct service. By excising a length of motor nerve fibres a spastic muscle or part of a muscle is permanently paralysed and the balance between an overacting group and its opponents is restored. The method has the advantage of lending itself to careful adjustment, with experience, the exact amount of paralysis

produced being varied to suit the particular case. There is, indeed, the theoretical objection that if too much is done there is no possibility of undoing it, except by attacking the nerves to the opponents, but as a matter of fact, as Bankart and others have stated—and the author's experience agrees with this—the error is practically always in the direction of doing too little rather than too much. Crushing a nerve, injecting a nerve with alcohol, or both, and intraneural division have all been advocated with the idea of producing only a temporary paralysis, yet by this means obtaining a balance of opposing muscle groups. It may, I think, be fairly stated that these methods are much more uncertain in their ultimate results; they have not been employed by us to any extent. It is claimed by some that the Stoffel operation produces the result immediately and does away with the necessity for apparatus afterwards. This is, I think, a mistake. It is true of some deformities—for example, adductor spasm, where no splintage is necessary after the wounds have healed—but it is certainly unwise to make it a general rule. In equinus deformity a night shoe to hold the foot in the neutral (that is, the right angle) position is essential for some months after correction, by whatever operative method this be done. The deformity can, and does, relapse after a Stoffel operation on the internal popliteal nerve if care is not exercised. It is our experience that while one deformity is best dealt with by the Stoffel method, another is corrected with greater certainty by tenotomy or an open lengthening of a tendon. In older children with severe deformities neither method yields such good results as a combination of the two.

Drop-foot.

The first essential is to see whether this is due only to spasm which can be entirely overcome by firm pressure against the ball of the foot or whether anatomical shortening of the calf (real contracture) has supervened. If the muscles are short, the tendo Achillis should be lengthened by the open method; if the deformity is due to spasm only, a Stoffel operation on the internal popliteal to paralyse a portion of, and thus weaken, the gastrocnemius and soleus may be done. If the amount of nerve fibres to be excised is judged correctly a very pretty result may be obtained, but not, I think, superior to that obtained by a carefully performed tendon lengthening. After an extended trial of both methods (over 60 operations on the internal popliteal nerve in the last 130 cases operated upon) the author is still unconvinced that the Stoffel method for this particular deformity has any advantages over tendon lengthening. The tendon lengthening is the better operation, but it should be done with care.

After the tendon has been divided by the "Z" method through an incision to the inner side of it and the upper end allowed to retract, the two portions are stitched together in such a position that the upper end is pulled on by the lower just before the foot reaches the right angle as the foot is raised towards dorsiflexion. Before the tendon is sutured the other tight structures—for example, posterior ligaments of the ankle-joint, etc.—should be thoroughly stretched. The foot is held in slight equinus by a malleable iron splint for five or six days and then gradually brought to a right angle and retained in this position till the end of the sixth week. Walking with a shoe wedged up on the inner side, to check the valgus tendency which is usually seen after correction of the equinus, is now permitted, while a rectangular tin shoe is worn at night for several months. A few simple exercises with the object of training the child to control the foot more perfectly and carry it through its full range of movement, particularly dorsiflexion and plantar flexion, are useful.

The Stoffel operation is performed through a vertical incision exposing the internal popliteal and its branches. On the superficial aspect of the nerve are two columns of fibres, lying close together and fusing above. The inner divides into the cutaneous (ramus communicans tibialis), running on in the mid-line, and the branch to the inner head of the gastrocnemius. The outer divides into a large soleus branch (this muscle receives another branch lower down) which runs down in the mid-line deep to the

cutaneous branch, to disappear between the two heads of the gastrocnemius, and a branch to the outer head of the gastrocnemius. The fibres resected depend on the degree of spasm present, and consist of the whole of the soleus branch and a half to two-thirds of the branches to each head of the gastrocnemius. In small children these nerves are difficult to split, and some surgeons prefer to excise them completely and vary the amount removed of the soleus supply. The knee should be kept extended on a splint with the foot at a right angle for three weeks to allow healing of the wound to be complete and the wound free from scabs before flexion is permitted. The scar has shown a curious tendency to crack and become thickened in a few cases, so that eventually a keloid scar develops with ulceration at the flexure.

Varus and Valgus.

As already stated, valgus is commonly seen after correction of equinus though not present before operation, but in some it is obvious when the case is first seen, even without any marked equinus being present. Varus is much less common. These are difficult deformities to correct with nicety, and the feet require careful watching to guard against over- or under-correction. The varus may disappear when the equinus is corrected, but tenotomy of the tibials may be necessary. This is best done by the open method, as in these cases the tibial tendons fail to unite after simple division. Valgus may be corrected by either method—the nerve operation or tenotomy of the peronei—and the author has had occasional pleasing results with both. Further experience is necessary before deciding which is the better. As considerable variation is met with in the exact distribution of the peroneal nerve and its branches, the musculo-cutaneous nerve should be followed down in the substance of the peroneus longus till the last muscular branch, to the brevis, is reached.

Knee Flexion.

In most cases a Stoffel operation on the sciatic nerve, or rather its branches to the hamstrings, gives better results than division or resection of a portion of the hamstrings. When anatomical contracture is present these tendons must be divided, but even then, particularly in older children (10 to 14 years of age), a Stoffel operation should be performed in addition. The nerves usually resected are the whole of the branch to the long head of the biceps, the whole of the branch to the semi-membranosus, and a portion, varying with the degree of spasm, of the branch to the semitendinosus. The knee is kept extended on a splint until the wound is healed; walking apparatus to prevent flexion of the knees is necessary only in quite exceptional cases. Exercises to improve the power in the extensors of the knee are useful.

Adduction of the Hip.

Here the nerve operations are unquestionably better than division of the adductors or resection of portions of them. Stoffel tackles the obturator nerve in the thigh, just above the upper border of the adductor longus. This approach is necessary when it is desired to excise only the anterior branch, but when the spasm is severe and the whole nerve is to be divided the abdominal extraperitoneal route is to be preferred. This approach I learnt from my colleague Mr. Tyrrell Gray, who was, I believe, the first to use it in spastic cases. The wound is less likely to become contaminated than one on the thigh by a child with dirty habits, and the whole nerve can be removed with greater certainty. The presence of an accessory obturator is the only possible source of error; this was met with twice—in a unilateral case and on one side of a bilateral case. It is an easy matter to isolate the nerve on the lateral wall of the pelvis as it approaches the obturator foramen. After the operation the thighs should be held in moderate abduction, just sufficient for nursing purposes, until the wound is healed. The two sides can be reached through a single paramedian incision, the peritoneum being stripped from the parietes in a downward and outward direction till the pelvic brim has been reached and passed. The results of this operation are extremely satisfactory and much more certain than after division of the muscles. Very rarely is there any suggestion of overcorrection.

Internal Rotation of the Leg.

Operation on the Stoffel principle would seem to have advantages over detachment of the muscles from the ilium as originally suggested and practised by Sir Robert Jones. The object of the former of these two procedures is to paralyze the internal rotators of the hip—namely, the tensor fasciae femoris and anterior fibres of the gluteus medius and minimus. Some surgeons excise the superior gluteal nerve as it enters the buttock, but I prefer to limit the paralysis to the portions of the muscles named, and thus avoid weakening the abductors unnecessarily. A vertical incision is made from the iliac crest to the great trochanter down to the periosteum. The terminal part of the superior gluteal nerve is found between the muscles, and a portion excised. The incision in the muscles must necessarily divide any other twigs of the nerve passing to the anterior parts of the glutei muscles. The result is entirely successful. There may be internal rotation of the tibia below the knee due to spasm of the popliteus muscles. The obturator nerve should always be resected when the superior gluteal is divided.

Flexion of the Thigh.

At present we only have division of the muscles—namely, the tensor fasciae femoris and psoas—as a possible means of dealing with the deformity.

The Arm.

The arm, as already stated, is much more difficult to deal with than the leg, for various reasons. The movements of the hand and arm are more specialized and finer; we more often find a diminution of the power of initiating impulses to the hand, and, more important still, the patient has little incentive to use the limb, being able to do almost everything with the other hand. A child cannot walk without using both legs, but can do most things with only one hand. A comparatively mild case, in which the voluntary control of the fingers is fairly good but in which the pronator spasm is a distinct drawback, can be considerably improved by dividing the tendon of the pronator radii teres, but an even better result can be achieved by following Stoffel. He attacks the median nerve and excises the branches given off to the pronator radii teres, the flexor carpi radialis and palmaris, all of which are pronators to some degree. It is not necessary here to enter into details of the operation, which can be read by those who wish for further 'information,' but we would emphasize the importance of using a battery to test the nerves isolated by dissection, as the bundles in the median nerve and the arrangement of the branches are extremely variable. While the internal popliteal is extraordinarily constant in its minute anatomy, the median, in our experience, cannot be relied upon in the least to conform to textbook description. Where the ulnar deviation with flexion of the wrist is marked we have, in addition, attacked the nerve supply of the flexor carpi ulnaris through a separate incision. If the flexor spasm of the fingers and thumb is marked, the column in the median nerve passing to the muscles concerned can be isolated and a fraction of it excised with benefit. The column is situated on the side opposite to the column going to the pronators—namely, on the postero-internal aspect of the trunk. There is no doubt that, as in the leg, the most satisfactory results are obtained in the milder cases. When the control of the hand is not too bad, though the pronator spasm is marked, the results more than justify the operation. Plaster may be used with advantage for holding the forearm in full supination for three or four weeks after operation, the wrist, of course, being dorsiflexed.

After-Treatment and Results.

As already stated, massage by itself is not of any material benefit except possibly, and then only to a small extent, in cases with one leg affected, and this leg showing signs of diminished growth, and perhaps to aid recovery in overstretched muscles after an operation on their opponents. The only thing of real benefit is patient and persevering training in walking and using the affected arm. A rectangular night shoe, with the sole plate inverted to check valgus, or everted if varus is present, should be used for several months after correction of the equinus. A splint to hold the knee extended is also useful in bad cases,

while a removable supination splint of plaster for the arm is also of benefit at times. Walking-irons extending up to the hips are only necessary in quite exceptional cases, usually in older children in whom the deformities have been of long standing; and occasionally a short outside iron and valgus "T" strap are of use. In the vast majority of cases the rectangular night shoe is the only apparatus necessary. The results in the milder cases are most gratifying to the parents and surgeon. In the worst cases the patient may be enabled to walk in some sort of fashion—a thing quite impossible before operation. In the majority that are worth operating upon at all—and most cases fall within this category—a decided improvement, at any rate in walking capacity, can be achieved, and this is usually accompanied by general improvement in the child's mentality.

These cases exhibit a quite extraordinary tendency to the development of a keloid condition of the scars resulting from operations. I am not prepared to state exactly the percentage which show this complication, but that this is unduly high I have no doubt. A scar may be affected in part only or in the whole of its length. In a child in whom some six or more incisions have been made every scar may be more or less affected. As a rule the condition is of moderate severity and gives rise to no trouble of any kind; but in certain situations—for example, the bend of the elbow or back of the knee—cracking and ulceration may occur. Even more rarely the scar is said to be sensitive or painful. Special care in splinting after operation is necessary in these situations. The cause of this curious incidence of keloid is difficult to find. The presence of a low-grade infection seems probable, but sepsis in the ordinary meaning of the word was certainly not the cause in my cases. The habits of these children are far from clean, and they are difficult cases to nurse and keep at rest, but even so one very rarely experiences any trouble as regards the healing of a wound.

HYOSCINE IN POST-ENCEPHALITIS LETHARGICA;

WITH SPECIAL REFERENCE TO ITS INFLUENCE ON CARBOHYDRATE METABOLISM.

BY

P. K. McCOWAN, M.D.ED., J. S. HARRIS, M.D.ED.,

AND

S. A. MANN, B.Sc.LOND., F.I.C.
(From the Pathological Laboratory, Maudsley Hospital, London,
and West Park Mental Hospital.)

INTRODUCTION.

THERE is little doubt that investigations into encephalitis lethargica will, as prophesied by von Economo, lead to a better understanding of the neuroses and psychoses, for this recently recognized disease affords us an unexpected insight into the psychological and physiological mysteries of mental mechanisms. This paper is based on clinical and laboratory work carried out at West Park Mental Hospital and the Maudsley Hospital. Being convinced, as the result of clinical experience, that hyoscine is in the nature of a specific in the treatment of post-encephalitic Parkinsonism, it was considered an interesting line of research to try and find objective proof of its action on the bodily mechanisms in such cases. We chose carbohydrate metabolism as represented by the blood sugar curve, and our investigations show how this is influenced by hyoscine.

CLINICAL EFFECTS FOLLOWING THE INJECTION OF HYOSCINE.

(A) In the Normal Person.

The subcutaneous injection of 1/100 grain of hyoscine hydrobromide is followed in from ten to fifteen minutes in the normal person by dryness of the mouth and throat,

a sensation of giddiness and a slight degree of mental confusion; some inco-ordination resulting in slight slurring of the speech and inability to walk straight; marked impairment of accommodation, with consequent difficulty in reading any but the largest print. These unpleasant early phenomena are followed by a feeling of laziness or fatigue; a great effort is required to perform the simplest of movements, and if left to himself the individual will settle down in a chair and soon fall asleep, remaining in this state for three to six hours. To what cause this remote effect (sleep) can be attributed is a question difficult to answer, and no very definite statement can be made. In view of the well known sedative effect which hyoscine exerts in acute mania it would seem probable that it acts on the motor side of the neuro-muscular arc, causing a marked diminution in muscular excitability and movement, with a consequent decrease in the number of stimuli reaching the higher centres from this source. In any case the action of hyoscine in the normal person is definitely depressant in character, and hence is quite different from that produced in a person suffering from post-encephalitic Parkinsonism.

(B) In Post-encephalitic Parkinsonism.

The immediate effects of hyoscine in the encephalitic are indistinguishable from those met with in the normal person—namely, dryness of the mouth, interference with accommodation, inco-ordination, etc. The later or remote effects in the amyostatic post-encephalitic patient with Parkinsonism, however, present a marked divergence from those found in the normal person. A short period of drowsiness, lasting for about two hours, is often noticed, and is followed by signs of physical and mental improvement. In some cases these beneficial results are more marked than in others, but in practically every case, given the correct dose, some improvement is obtained. On the physical side there is diminution of the generalized muscular rigidity, lessening of the tremors of the face and extremities, and disappearance of the excessive salivation and lacrymation which are such frequent and distressing features of this condition. The patient becomes more alert, and instead of being content to sit huddled up in a chair will occupy himself with light tasks; his gait is much freer, and shuffling less pronounced; some faint expression creeps into his mask-like countenance, and he begins to exhibit some interest in things outside himself. His articulation, though lacking in timbre, is less slurring and hesitant, he speaks much more freely, and his speech, like all his actions, shows a diminution of the retardation which is such a prominent feature of the disease. Since the action of hyoscine is probably entirely on the motor side, it follows that in this action must lie the explanation of the increased sense of well-being, the diminution of the apathy, and the brighter outlook of those who benefit by its administration. It supports the thesis that, though the brain is the seat of the psyche, the functions of the mind are dependent upon the whole body and the harmonious interaction of all its parts, as implied in the time-worn dictum *Mens sana in corpore sano*.

In the encephalitic it is always difficult to discount the element of suggestion in the appraisalment of the benefits derived from any particular form of treatment, but extended experience of the administration of hyoscine in this disease leaves no doubt that in many cases it is, quite apart from suggestion, of profound benefit. The following cases illustrate this.

1. A girl, aged 17, who suffered from Parkinsonism with excessive salivation, marked general rigidity, and who was completely dependent, requiring hand-feeding, washing, etc., immediately improved on hyoscine 1/1000 grain daily, and after three days was up and about, able to dress and feed herself, was alert and cheerful, and by the end of a week was entering into the social life of the ward, including dancing.

2. A man, aged 50, suffering from well marked Parkinsonism, with rigidity and mask-like features, excessive salivation, being entirely dependent and depressed, on hyoscine 1/75 grain daily became quite active and cheerful, and his rigidity, tremors, salivation, etc., disappeared. In this case, in order to eliminate the element of suggestion, sterile water was repeatedly substituted for the hyoscine, and though quite unaware of this he invariably failed to respond by any improvement.

It must be more than coincidence that the hysterical element is here found to an extent not approached in any

other group of patients found in a mental hospital. We would suggest that the site of the lesion in these cases is all-important, and that a clue may here be found to the discovery of an organic basis for the so-called functional disorders or psychoneuroses. No gross material change is to be looked for, but subtle biochemical or biophysical abnormalities may be present. The site referred to is the basal ganglia. Certain it is that this area is affected in encephalitis lethargica, with its hysterical aura, and in addition there is little doubt that the same area is of primo importance in the instinctive and emotional life of man which composes the mental mechanisms that are at fault in the neuroses. Support is lent to this hypothesis by the fact that in chorea and Wilson's disease we have two other diseases which, like encephalitis lethargica, have lesions of the basal ganglia and psychic manifestations of an hysterical nature.

The hyoscine may be administered either subcutaneously or by the mouth. When given subcutaneously it seems to act more powerfully and its effects continue for a longer period than when the oral method is employed. The question of dosage is of some importance. It is best to commence with fairly small amounts and increase until the required effects are obtained. If given hypodermically a start can be made with 1/150 grain once a day, and this amount can if necessary be increased until as much as 1/50 grain is being given once a day. When administered by the mouth larger doses may be given three daily, preferably just after meals, since if given before food the dryness of the mouth and throat makes mastication and deglutition somewhat difficult and unpleasant.

EFFECT OF HYOSCINE ON THE BLOOD SUGAR CURVE.

Method Employed.

In order to discover the effect of the injection of 1/100 grain of hyoscine hydrobromide on the blood sugar curve in the normal person and in the post-encephalitic the following precautions were taken: The person whose blood sugar curve was about to be investigated was starved for about twelve hours (from 8 p.m. till about 9 a.m.). He was kept in bed or seated comfortably in a chair, and the temperature of the room was maintained at about 65° F. A specimen of blood was taken to ascertain the fasting blood sugar level, and then 50 grams of glucose in 6 oz. of water were given by the mouth, and at the same time 1/100 grain of hyoscine hydrobromide was injected subcutaneously into the arm. Thereafter specimens of blood were taken at fixed intervals (3/4 hour, 1 1/4 hours, 1 3/4 hours, 2 1/4 hours) from the time when the glucose and hyoscine had been administered. In post-encephalitic patients it was necessary first of all to establish blood sugar curves by giving glucose only; the effect of hyoscine was investigated the following morning.

The Effect of Hyoscine on the Blood Sugar Curve of the Normal Person.

Eight nurses and three medical colleagues were selected in order to establish the effect of the normal blood sugar curve, and they were all in good health. Below are tabulated the blood sugar readings at the fixed intervals of time.

No.	Sex.	Fasting Level.	50 Grams Glucose + 1/100 Grain Hyoscine.			
			After 45 Mins.	After 75 Mins.	After 105 Mins.	After 150 Mins.
1	F.	.09	.128	.103	.122	.120

6	M.	.12	.156	.144	.164	.122
7	M.	.10	.112	.117	.103	.118
8	F.	.10	.15	.136	.13	.098
9	F.	.114	.125	.143	.143	.103
10	F.	.106	.12	.13	.128	.09
11	F.	.098	.1	.116	.136	.125

Reference to the table will show that the effect of 1/100 grain of hyoscine hydrobromide on the blood sugar curve following the ingestion of 50 grams of glucose in the normal individual is a general depression of blood sugar values. These lowered values may be associated with a sluggish rise and fall of the curve, and it is not unusual to find a secondary rise of the blood sugar curve resulting in some degree of hyperglycaemia after two hours following the glucose meal and drug injection (Fig. 1).

At first sight it would appear that hyoscine has an inhibiting action on the factors governing both the rise and the fall of the blood sugar curve, but, as will be seen later, the results obtained with the cases of post-encephalitis

FIG. 1.—Blood sugar curves of normal person. N, After 50 grams glucose. H, After 50 grams glucose plus 1/100 grain hyoscine.

lethargica in general show the same depression of blood sugar values with acceleration of the fall of the curve (Fig. 2). The main effect of hyoscine on the blood sugar curve is, then, a depression of the glycogenolytic reaction and a variable glycogenetic response. Atropine gives a similar result, both as regards depression of the blood sugar values and the accelerated fall of the curve in cases showing a sustained hyperglycaemia after glucose ingestion.

The pharmacological action of these parasympathetic-mimetic drugs gives rise to inhibition of the external secretion of the pancreas and general arrest of the secretions of the alimentary tract. Inhibition of the internal secretion of the pancreas would lead to impaired glycogenesis and a blood sugar curve showing sustained hyperglycaemia; this is not evident in the blood sugar curves with hyoscine (or atropine). But with the general arrest of alimentary secretions the alteration in the blood sugar curve may find explanation either in diminished or retarded rate of absorption of the sugar from the intestines, or on the lines of Allen's theories regarding treatment in diabetes; with arrest of the external secretion of the pancreas there may be increased activity of the internal secretion with corresponding glycogenesis.

Effect of Hyoscine on the Blood Sugar Curve of the Post-encephalitic.

The majority of the blood sugar curves after glucose alone are abnormal in type; some show high blood sugar values, and sustained hyperglycaemia is the rule.¹ The results of the injection of hyoscine simultaneously with the glucose ingestion make it possible to classify the cases

FIG. 2.—Blood sugar curves of post-encephalitic Parkinsonian. A, After 50 grams glucose. B, After 50 grams glucose plus 1/100 grain hyoscine.

Case 13 was the only instance in which this reaction was indefinite. All these cases showing an "improved"

Table showing the Blood Sugar Percentages in Post-encephalitic Patients—

blood sugar curve benefited clinically from the administration of hyoscine.

The second group consists of cases (14 to 20) which did not exhibit Parkinsonism and in whom this "improved" blood sugar curve following hyoscine was not evident. There is a variable depression of blood sugar levels, many of the cases showing a secondary blood sugar rise, giving blood sugar curves of the type shown to occur after hyoscine injection in the normal individual. In these cases the administration of hyoscine was not associated with clinical benefit.

The above results show that in patients with post-encephalitis lethargica, those with Parkinsonian symptoms receive most benefit from hyoscine therapy, and that this clinical improvement is coincident with an "improved" blood sugar curve.

CONCLUSIONS.

1. Hyoscine is of undoubted value in the Parkinsonism following encephalitis lethargica.
2. This value is objectively demonstrated by its effect on the blood sugar curve, which is made to approximate to the normal type.
3. This improvement is due to a specific action of the drug, though suggestion may be a subsidiary factor.
4. This action of hyoscine is only temporary, but the prolonged use of the drug does not lead to tolerance or any deleterious effects.
5. The hysterical element in this disease is probably due to lesion of the basal ganglia, and it is suggested that an analogous lesion may account for similar symptoms in hysteria, chorea, etc.
6. Though in the majority of cases the full benefit of hyoscine can only be obtained by hypodermic administration, there is no doubt that in many cases considerable benefit follows its oral exhibition.

In conclusion we would like to thank Dr. Golla, the Director of the Pathological Laboratory of the Maudsley Hospital, at whose suggestion these investigations were undertaken, for his unflinching interest. To Dr. Roberts, the medical superintendent of West Park Mental Hospital, we are indebted for the permission to publish the particulars of certain cases.

RHEUMATIC AFFECTIONS:

SOME OBSERVATIONS ON THEIR TREATMENT.

BY

J. LESLIE ORR, M.B., CH.B. GLASG.,
GLASGOW.

So much has been written on "rheumatism" that it is not without a little hesitation that I attempt to add to that mass of literature; I feel, however, that the findings set forth below, in one section especially, are worthy of note.

The greater part of the investigation was made in Manchester, a city noted for its humid climate. The conditions which I wish to discuss are: acute rheumatism or rheumatic fever; rheumatoid arthritis; osteo-arthritis; fibrositis; and Still's disease. It is in connexion with the first mentioned condition that most of the work has been done.

Acute Rheumatism.

Rheumatic fever is typically an acute febrile disease, characterized by polyarthritis and liable to be complicated by endocardial disease or hyperpyrexia. In a very large proportion of cases treatment, including keeping the patient in bed between blankets and the administration of sodium salicylate, is most effective; but there are patients who for some reason or other do not respond to this kind of treatment, or who respond up to a point and then continue in a state of irregular pyrexia for many days or weeks. Whether this failure to clear up is due to there being a more virulent strain of streptococcus, a less robust patient, or a superimposed infection, I shall not venture to say definitely. It seems quite certain, however, that most people who suffer from the effects of permanent damage to the heart belong to the "non-clearing up" group. It was with a view to promoting the prevention of cardiac damage and subsequent disability that the present investigation was commenced.

In all cases of acute rheumatism an examination of the lungs, throat, teeth, and urine was made. Fluid was removed from joints which were swollen on admission, or which remained swollen and in a state of subacute inflammation. An attempt was made to isolate an organism from these various situations, and the greatest number of positive cultures was made from the throat and teeth. A long type of streptococcus was found, and this organism was also found in fluid removed from joints, most frequently the knee-joint. Negative cultures resulted from all examinations of the urine.

An autogenous vaccine of the residual type was prepared and given subcutaneously; salicylate treatment was stopped. The first dose was 3 minims of a suspension containing 500 organisms in the minim, and thereafter injections were given every third or fourth day, increasing the dose, when possible, by 3 minims on each occasion.

In all cases a reaction followed the first injection; headache, pyrexia, sweating, and pain in the affected joints were the chief symptoms, and usually lasted for twelve to twenty-four hours. In some cases marked reaction was noted in the second and subsequent doses, but in the majority of cases only a slight reaction was perceived after that following the second dose.

A definite improvement in the patients' condition resulted, and as a rule by the end of a fortnight the patients were able to sit up in comfort, and the swelling of the joints had either completely or considerably subsided. In those cases where cardiac murmurs had been noted earlier in the illness no abnormality was noted when the patient was ultimately discharged.

The following cases have been selected from the series:

CASE I.

A man, aged 42, admitted January 26th, 1924, complained of severe pain and swelling in both knees, the left ankle, and both elbows. The throat was sore and acutely congested; the temperature was 102.4°, the pulse 104, and the respirations 28.

Treatment with sodium salicylate in large doses internally, and the application of methyl salicylate to the affected joints, was commenced immediately after admission. A few hours later the patient was very delirious and this continued through the first night. The specific gravity of the urine was 1028, albumin was present, but no other abnormal constituents. On January 29th most of the joints had improved. On examination of the heart on this date an apical systolic murmur was noted. A small amount of

fluid was removed from the right knee-joint, which did not show any improvement, and sent for bacteriological examination; a throat swab was also sent, and in each case a pure culture of a streptococcus was obtained. A vaccine was prepared and treatment with this commenced. The first dose of this autogenous vaccine was 3 minims (equivalent to 1,500 streptococci), given subcutaneously; a severe reaction followed, the temperature rising to 102.3°. Owing to the marked reaction further administration of the vaccine was withheld for one week, when 6 minims were given; again there was a reaction, but this time less severe. The third and fourth doses, each of 6 minims, were given at weekly intervals; thereafter increased doses were given every third day. The vaccine was discontinued on March 18th; by this time all pain and swelling had completely disappeared, and the heart presented no abnormality in the nature of a murmur. Hydrotherapy and massage, which had been employed for a few days, were continued, and the patient was gradually able to get up and about, and soon became his normal self.

Four months later the patient looked and felt well. He was at work and made no complaints which would suggest cardiac trouble; his heart was examined and no abnormality found. He is now in the South of England and enjoys good health.

CASE II.

A man, aged 49, was admitted on February 13th, 1924, complaining of pain and swelling in both ankles and the left wrist. Examination of the heart revealed the presence of endocarditis, and there was a systolic murmur at the apex. Sodium salicylate and methyl salicylate treatment was commenced, and on February 15th the upper left molar tooth was extracted. Above the level of the gum the tooth appeared quite normal, but the root exhibited disease; from it a streptococcus was recovered and a vaccine prepared. On February 20th 3 minims of the vaccine (equivalent to 1,500 streptococci) were given, and a few hours later a moderate reaction followed. However, when 6 minims of the vaccine were given a week later there was a very marked reaction, the temperature rising to 103.2° and the pulse to 128. Within a few hours the patient complained of sore throat and pain in the submaxillary region of the right side, and a day or two later he developed a right-sided quinsy which required incision. It is just possible that the 6-minim dose was given too soon, and it either coincided with or precipitated the quinsy. On March 20th the 6-minim dose was repeated, and a slight reaction followed. On April 12th a 12-minim dose was given and no reaction followed.

This patient was discharged on May 17th; there was slight stiffness in the right foot, but the heart was sound. Four months later he was back at work, made no complaints, and his general condition was very satisfactory. Just recently I heard that he was still working as a carter and exposed to the elements daily; he made no complaints.

Only a summary of the observations on the other conditions will be given.

Rheumatoid Arthritis.

Protein shock with *B. coli* vaccine given intravenously was the method adopted in this disease, and about 60 per cent. of the cases treated were undoubtedly benefited. On no occasion was an autogenous vaccine obtainable. Throughout the whole of the treatment of this affection only one accident occurred. This was a case of anaphylaxis, and after a few hours the patient completely recovered. No history of previous vaccine or serum treatment was elicited.

Osteo-arthritis.

Vaccines and protein shock were tried without the slightest improvement. Massage with active and passive movements were the only methods of treatment which relieved the intense suffering, and, with the exception of anodynes, drugs, given internally or externally, proved useless.

Fibrositis.

Treatment with collosol sulphur and iodine was tried. The result was indefinite, and equally good results followed the prolonged administration of potassium iodide with potassium citrate in the form of a mixture. Massage and hydrotherapy aided recovery.

Still's Disease (Children).

Salicylate treatment was first tried, but proved useless, and protein shock failed. An attempt was then made to isolate an organism and prepare a vaccine. An autogenous streptococcal vaccine was made, but its administration failed to produce any reaction at the time or any improvement, even after prolonged administration.

Conclusions.

It may appear that in many cases ordinary sodium salicylate treatment in acute rheumatism is sufficient, but I would point out that the heart is a highly specialized organ, and, once it has been damaged, repair in most cases,

perhaps all, is impossible. Treatment of acute rheumatism with an autogenous vaccine at the beginning of the illness has a definite effect in decreasing the tendency towards cardiac and other complications, and hastens recovery in other cases which might lapse into chronic deformity or tend towards hyperpyrexia.

Protein shock treatment is limited to rheumatoid arthritis; massage, hydrotherapy, and electrical treatment may be utilized in all rheumatic affections, but are usually only required after the acute stage is past.

I am indebted to Dr. C. E. Jenkins (pathologist to Salford Royal Hospital) for the preparation of the vaccines, and would refer those who desire further information about the dosage to articles by him in the *BRITISH MEDICAL JOURNAL* (1921, ii, p. 846; 1922, i, p. 596) and the *Lancet* (1922). I have also to thank Dr. J. Dudgeon Giles, medical superintendent of Hope Hospital, Pendleton, and Dr. Henry Carre, medical superintendent of Woodilee Mental Hospital, Lenzle, for permission to make the experiments and publish the results.

PRESSURE BY THE MESENTERIC ROOT UPON THE DUODENUM WITH ABSENCE OF "DUODENAL ILEUS."

BY

GEORGE ROBERTSON, F.R.C.S.ED.,

HONORARY SURGEON, DUNFERMLINE AND WEST OF FIFE HOSPITAL.

The following case is instructive in view of the mechanical pressure theory of duodenal ileus held by some surgeons, and which I at much length have already attempted to disprove.¹

A multipara on the fourth day following the birth of her last full-time child got out of bed and soon felt giddy. A severe headache followed, and was accompanied by severe vomiting. No pyrexia existed. These symptoms continued for four weeks. Her doctor, who visited her daily, was at a loss to understand her condition. Vomiting was "propulsive" in type, of daily occurrence, was usually accompanied by headache, seldom by nausea. The vomit was partly digested food, and was occasionally bilious in character. By the end of a month the patient became very emaciated, and fits of a cerebellar type developed and became frequent. At this stage I saw her in consultation with her doctor. She was then considered too enfeebled for operation, and very soon she died. During the course of the illness only slight rises of temperature (the highest being 99.6° F.), and at many days' interval, were noted. As a rule the temperature was normal or subnormal, and the pulse rate very slow.

Autopsy showed (1) a tuberculoma, the size of a walnut, of the left cerebellum; (2) extensive tuberculous disease of the abdominal lymph glands. There was not a lymphatic area unaffected. Many of these caseous glands were as large as a small hen's egg, most were somewhat smaller. The mesenteric root was very thick and heavy with large caseous glands. There was not even a suggestion of "duodenal ileus."

The main factors that have been emphasized as capable of producing this mechanical obstruction were certainly present in this case—namely: (a) A very heavy and gross thickening of the mesenteric root where it crosses the duodenum. (b) A severe downward drag of the mesentery as a whole, the mesenteric lymphadenitis being very extensive. (c) A general visceroptosis. The intestines had been suddenly relieved from pressure by the birth of the child. The feeble lax abdominal wall of this multipara, nearing death from extensive tuberculosis, could furnish little support to the viscera.

Had the cerebral symptoms not supervened a surgical enthusiast might have been tempted to anastomose the duodenum to the jejunum. Here much dexterity would have been necessary to perform this operation *secundum artem* and still surmount the almost neoplastic mesenteric root.

Had an autopsy not been made a case showing all the main elements of production of duodenal ileus (obstructive) might have been lost.

The *British Journal of Surgery* for October, 1925, contains a very excellent article by H. P. Winsbury White (London), entitled "The pathology of hydronephrosis." In this contribution a careful and experienced observer has summarily disposed of the attractive but none the less fantastic theory of dilatation of the renal pelvis by the

normal and "abnormal" renal vessels—artery and vein. In the production of duodenal ileus the superior mesenteric vessels have an even smaller part to play than those renal vessels have in causing a hydronephrosis, for so far as I am aware nobody has claimed anatomical abnormality of origin for the superior mesenteric vessels when they are supposed to obstruct the duodenal lumen.

INTESTINAL OBSTRUCTION BY GALL STONE.

THE following report may be of interest in connexion with the series of cases of obstruction of the small intestine due to gall stones recorded by Mr. Bennett in your issue of March 27th (p. 565).

On March 10th I was asked to see a lady, aged 66, suffering from abdominal pain and vomiting. The history was as follows: For some months she had been treated from time to time by her doctor for gall stones; owing to her general condition being very poor no operation had been advised. She had had typical attacks of gall-stone colic, clay-coloured stools, and dark urine. On March 3rd she noticed that her motions were black, and she was suffering from generalized abdominal discomfort not severe enough to call her doctor. On March 8th she vomited, and had intermittent attacks of colicky pain centred round the umbilicus; the pains lasted about five minutes and recurred about every fifteen minutes. On the morning of March 8th she had a good action of the bowels.

The vomiting became more frequent, and I saw her on March 10th; the vomitus consisted of four small intestine contents, and her bowels had not been open since March 8th. An enema gave no result. The abdomen was distended and was tender all over. A diagnosis of acute intestinal obstruction was made, and she was admitted under my care in the West Cornwall Miners' and Women's Hospital, Redruth, for an immediate operation. When I arrived at the hospital I found that only five minutes before she had passed a small motion, formed and somewhat pale. Her general condition being very bad, and as she had not vomited since admission, it was decided to wait.

At 4 a.m. on March 11th, after a fairly comfortable night, she passed by the rectum a huge gall stone, 2 inches long and just over 1 inch through, and barrel-shaped. After passing this she felt very fit; there was no sickness and no pain. She was discharged from hospital two days later, and is now perfectly well.

This case is interesting in that, although a positive diagnosis was impossible, yet she had definite symptoms of gall-stone trouble, and also because of the fact that she escaped operation by passing a small motion five minutes before she would have gone on the table.

ARTHRITIC PURPURA AND PANCREATITIS FOLLOWING MUMPS.

THE following case seems to be of interest on account of the unusual symptoms following an attack of mumps.

On January 29th, during the recent epidemic, a school teacher, aged 26, contracted mumps. The parotid and submaxillary glands of both sides were affected, and there was rather severe and persistent gingivitis round the lower molars lasting for fifteen days. On the eighteenth day she sat up for an hour for the first time without any untoward results, but on the following evening, after sitting up for a short time, she was seized with severe pains in the neck and limbs, and almost simultaneously noticed a heavy petechial rash on both feet. The rash extended from the ankles over the dorsum of the feet and under the arch of the foot, and was followed briefly by fine scaling of the skin. There was no urticaria or rash elsewhere. No swelling of the joints was manifest, but pressure over either shoulder-joint, or raising the arms, caused considerable pain. The patient was kept in bed for four days, during which time the joint pains disappeared and the rash faded. On the next day she was up for about half an hour and felt quite well, but on the following day there was a faint purpuric rash on the feet, which, however, soon faded, and there were no joint pains.

On February 26th, just four weeks from the onset of the illness, on waking up she was suddenly seized with intense pain in the left loin. She vomited, and became very restless with pain and seemed to be rather collapsed. The attack seemed very similar to renal colic; the urine contained a heavy cloud of albumin, and on palpation there was great tenderness in the left loin, and

general tenderness over the left side of the abdomen. The tongue soon became very furred, the breath heavy, and all food was vomited at once, including water. The bowels, hitherto regular, were not opened during that day nor during the next three days. On February 27th there were two more attacks of pain in the back and in the left iliac fossa; the temperature rose to 99° F., and the vomiting continued. In the evening an area in the left flank where the pain had been most intense was seen to be covered with a bright petechial rash. In a later attack the pain was even more severe and radiated into the left groin. When it subsided a quantity of smoky urine was passed with a sediment of blood and several small tubular clots.

On the next day, March 1st, the patient seemed to be decidedly better. The urine was clearer. A catheter specimen was examined and found to contain blood cells, together with many uric acid crystals, a few hyaline and granular casts, and a few detached renal cells. An enema was given with a normal result.

As the abdominal pain and discomfort cleared up an area remained over the tail of the pancreas, which was tender on deep palpation, and this persisted for about ten days in some degree.

Examination of the faeces afforded some evidence of mild pancreatitis. There was no evidence of bleeding into the bowel.

The subsequent history of the case has been uneventful, except for the brief appearance of two quite faint purpuric rashes on the arms just above the elbows.

It should be added that the patient gives no history of rheumatism, or of previous liability to purpura, and that she was not taking any of the drugs which are liable to cause this disorder. The blood condition is normal.

St. Albans.

R. E. WILSON, M.B., B.Ch.

MALDEVELOPMENT OF OESOPHAGUS.

DR. THERON'S case of maldevelopment of the oesophagus (April 10th, p. 652) reminds me of a similar one which I met with about five years ago.

A very healthy looking infant, 2 days old, was brought to me by the district nurse, who had attended the mother, a multipara, in a normal confinement. She said the child took the breast strongly, but could not swallow, and I found that a soft catheter did not pass much below the level of the larynx. I sent the child into hospital, where it died two or three days later, and the surgeon agreed that there was a developmental occlusion, but unfortunately there was no autopsy.

By a curious coincidence the next issue of the *BRITISH MEDICAL JOURNAL* contained an editorial reference to a report on the comparative anatomy and development of the trachea and oesophagus, and remarked upon the rarity of this particular malformation. The investigator had found only a few specimens in the European museums.

Dr. Theron writes that luckily it is rarely met with in practice, although Professor Sir Arthur Keith says it is not uncommon.

Certainly the gross abnormality we encountered cannot very well be mistaken, and the children only survive a few days, but the lesser degrees, where the oesophagus is more or less patent, and opens into the trachea above the bifurcation, might be overlooked even by the pathologist, in an infantile death from respiratory disease, unless the condition were kept in mind. The termination in these cases would be death by suppurative pneumonia.

Hungerford, Berks.

WALTER DICKSON.

BROW PRESENTATION.

IN view of the recent request to medical practitioners to record cases of brow presentation, I think the following clinical details may be of interest.

1. A Chinese multipara had been in labour and the membranes had been ruptured, many hours before being seen by me. The case was one of twin pregnancy. The first child presented brow (left occipito-posterior) and the head of the second child lay behind the shoulders of the first. I was unable to change the presentation either to face or to vertex, and as I was very doubtful whether delivery was possible, even after perforation, the patient was transferred to hospital for Caesarean section. The mother and the second child survived, but the first child had died.

2. A Chinese primipara had been in labour for over forty-eight hours; a small loss of fluid had occurred twenty-four hours, and a much larger loss six hours, before the patient was seen by me. Foetal heart sounds could not be detected. The head was not fixed. On vaginal examination the cervix was half dilated and a brow presentation (right occipito-anterior) was found. Under chloroform anaesthesia an attempt was made to change the presentation to a vertex, but it failed; the change to full face was easy. As the presentation quickly reverted to brow, and as,

during these manipulations, the cervix had dilated fully, the face presentation was maintained by means of a forefinger hooked under the foetal chin while an assistant applied and locked the forceps. The head descended with moderate traction without difficulty. As the foetus was clearly dead, the head was perforated, with a view to minimizing maternal injury, and the mother made an uneventful recovery.

The cause of this brow presentation was not ascertained. Pelvic flattening, if present at all, was very slight. There was no uterine obliquity.

Penang, Straits Settlements.

JAMES GOSSIP, M.D.

Reports of Societies.

INCIDENCE AND SPREAD OF CHOLERA IN INDIA.

At a meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine on April 23rd, Dr. E. W. GOODALL in the chair, Sir LEONARD ROGERS read a paper on the conditions influencing the incidence and spread of cholera in India. The paper embodied the results of the monthly mortality returns for the last fifty years, together with an examination of the coincident meteorological data and of the views of previous writers on the subject.

In the cholera epidemics in India in 1817-19, and subsequently down to those in 1859-71, described by Bryden and Cornish, the disease appeared to have spread from its home in Lower Bengal over North-Western, Central, and Southern India in a series of waves of two to four years' duration at somewhat irregular intervals, the endemic area, according to Bryden, being limited to Bengal and West Assam.

Since 1877 the monthly cholera mortality for every district in India had been recorded, furnishing far more detailed information than the army and jail figures of Bryden's time, but they had not hitherto been utilized for a comprehensive study of the incidence and spread of cholera in India such as was here attempted.

A study of the average monthly cholera incidence and its comparison with the rainfall, temperature, and humidity in forty-five divisions of India showed (a) no uniformity of incidence, as the disease during the south-west monsoon was common in most parts of India, but at its minimum in the north and (b) a regular great increase in the incidence of the disease in all parts of India when the humidity rose to or below 0.400, such dryness of the atmosphere being an epidemic prevalence of the disease. The months in which cholera showed a great increase after the winter quiescent period in North-West and Central India were those in which the absolute humidity first rose to over 0.400, the seasonal increase in the epidemic areas being thus explained quite irrespectively of any spread from Bengal.

The average annual incidence of cholera was found to be highest in Assam, Lower Bengal, Bihar, and the eastern sub-Himalayan divisions of the United Provinces in Northern India, and in South-East Madras, all of which were areas with few or no months of absolute humidity below 0.400 and consequent continued prevalence of the disease throughout the year.

The present endemic areas—that is, areas in which the disease had never been absent for a single year in three recent decades—included the areas of high incidence already mentioned of Bengal, the United Provinces, and Madras, together with the low-lying west coast of Bombay, all with a constant absolute humidity of over 0.400, so the endemic areas were now far more extensive and scattered than the parts of Assam and Bengal indicated by Bryden in 1869.

The epidemic areas—that is, areas in which severe outbreaks occurred frequently after a year or two of complete absence of the disease—included the south and west of the United Provinces, all the Punjab, the Sind, Gujerat, and Deccan divisions of Bombay, and the whole of the Central Provinces.

Study of the figures showed a larger number of epidemics in the United Provinces than in Lower Bengal, and demonstrated that a number of the outbreaks spread from the endemic area of the United Provinces towards the Punjab, decreasing in intensity in proportion to the distance of the divisions from the United Provinces and the dryness of their climate. Similarly it was shown that the Central Provinces in recent decades were sometimes invaded from the east from the southern Orissa division of Bengal, occasionally from the north from the United Provinces, and frequently also from the west from the Deccan divisions, contrary to Bryden's conclusion that cholera always spreads from Bengal to the north-west over the United Provinces, or to the south-west over the Central Provinces to Bombay with the monsoon winds, the facts on which he based his theory being now explained by the effect of low absolute humidity in inhibiting epidemics.

The three most severe epidemics of modern times were next considered in the light of the foregoing data and in connexion with the meteorological conditions associated with them: the spread of the 1875-77 epidemic was mapped out and shown to have spread largely through pilgrims from separate endemic foci north-west from Bengal and the United Provinces, east and south from Bombay, and north from Ceylon or Southern Madras, and in each area of very high incidence the epidemic was shown to be associated with great deficiency of the previous rainfall, accompanied by drought with bad water supplies, and often with famine. That of 1891-92 was spread mainly in the first year by a rarely occurring great Ganges pilgrimage, aided by deficient rains, and in the second year by continued deficient rainfall, but especially by the Hardwar pilgrims; and the most severe epidemic of all, in 1900, was once more associated with very exceptional failure of both the monsoon and the succeeding winter rains over very large areas of India. A table was exhibited showing the epidemic prevalence in each of the forty-five years in which the total cholera mortality in India was much over the average, and out of twenty-five infected areas, in no fewer than twenty-four previous greater or less deficiency of the rains preceded the cholera exacerbations, and in the one exception in the United Provinces, in 1894, very exceptionally high humidity throughout the winter months was followed by unique early recrudescence increase of the disease culminating in an epidemic.

By watching the climatic conditions influencing the seasonal and annual incidence of cholera in any area to which attention had now been drawn, increased or epidemic prevalence could usually be foreseen in time to take steps to lessen its spread, especially by pilgrims, by inoculating them against the disease before attending religious and other gatherings in cholera infected districts. The Punjab, Sind, Gujarat, and Deccan divisions of Bombay, and the Central Provinces, so liable to invasion by epidemics, should especially endeavour to secure a wider application of this simple means of lessening the cholera mortality. The sanitation, and especially the provision of a pure water supply, in all important pilgrim centres should be a first charge on Imperial and provincial revenues under reliable sanitary administration.

In the subsequent discussion, Sir HAVELOCK CHARLES described the professional opinion on the causation of cholera when he first entered the Indian Medical Service in 1882, and gave some interesting examples from his personal experience to illustrate the importance of a pure food and water supply.

Colonel GILL, after paying personal tribute to the value of the Rogers treatment in cholera, referred to the gradual development of the view that cholera in India had some relation with meteorological conditions, and he recalled by way of comparison the work of the Plague Commission, which showed that the tension of aqueous vapour must be at least 0.36 or thereabouts before an epidemic could occur. In plague, and also, as he himself had recently shown, in malaria, the absolute humidity exercised its effect on the insect vector, but he confessed he saw some difficulty in explaining the observed correlation in cholera, unless it could be shown that the susceptibility of the human being responded in some way to changes in the humidity of the atmosphere. He strongly urged that further inquiry should be made into this question.

Colonel GRAHAM said that inquiries were now in progress in three districts of India with a view to elucidating the question of the endemicity of cholera. He referred to the interesting work which had recently been done in Manila on the non-agglutinating vibrios and their role in the causation of true cholera epidemics. He emphasized the difficulty of inducing the ryots to consent to inoculation when cholera was absent. Trials were now being made, however, with Besredka's oral vaccine in Madras under the supervision of the Director of Health, and the results would be studied with great interest.

Dr. WHEATON and Fleet Surgeon HOME also contributed to the discussion, and Sir LEONARD ROGERS briefly replied.

CERVICAL CARCINOMA AND VENEREAL DISEASE.

At a meeting of the North of England Obstetrical and Gynaecological Society held in Liverpool on March 19th, the President, Mr. W. GORDON (Leeds), in the chair, Miss RUTH NICHOLSON (Liverpool) showed three cases of carcinoma of the cervix occurring in women under treatment for syphilis and gonorrhoea.

Miss Nicholson said that during the seven years in which she had had charge of two clinics for venereal diseases these three cases of carcinoma of the cervix had occurred among some 1,500 patients. Arthur Helme had reported in 1902 a case associated with double prostatic carcinoma in a young nullipara, aged 23, married one year; the husband was known to have suffered from gonorrhoea and syphilis. Gordon Luker had described in the *Proceedings of the Royal Society of Medicine* for 1922 a case of squamous-celled carcinoma of the cervix in a young 2-paras, aged 28, under treatment for gonorrhoea in the London Hospital venereal department. He remarked that no other case of a similar nature had arisen during the seven years the clinic had been in existence, emphasising the fact that the local treatment might have acted as an irritant. Herbert Spencer, in his *Lettsomian Lectures* in 1920, expressed the opinion that the relation of syphilis, soft sores, and gonorrhoea to cancer of the cervix was close; he had twice seen carcinoma of the cervix develop in patients who had previously had chancre of the cervix. These were the only cases and references she had found recorded. The notes of her three cases were as follows:

CASE I.

A single woman, aged 25, known to be a prostitute; no pregnancies had occurred. Miss Nicholson first saw her in 1919, when she was being treated for syphilis; there were no notes relating to her condition on admission to the home. She was also suffering from a chronic urethritis and endocervicitis, and though at the time gonococci could not be demonstrated in the discharge, later she developed salpingitis, and gonococci were then definitely shown in vaginal smears. The treatment for syphilis was continued, and local applications of protargol and glycerin were used for the cervix for a period of five months. She came again in 1921, with a recurrence of vaginal discharge; there were then no signs or symptoms of carcinoma. Two and a half years later, in December, 1923, she came complaining of intermenstrual haemorrhage of one year's duration. She was transferred to the Stanley Hospital, where Miss Ivens performed hysterectomy. The pathological report was "a squamous-celled carcinoma." She was still alive, two and a quarter years later, but the malignancy had recurred.

CASE II.

A woman, aged 40, married for twenty years, five pregnancies, all full-time living children. Forceps delivery was necessary in the first labour, but the others were normal; the youngest child was 8 years of age. The patient was first seen in 1921, with well marked signs of secondary syphilis and a positive Wassermann reaction. No primary chancre was discovered. There were no signs of gonorrhoea at that time, and smears from the cervix and vagina were negative. She had gone to Germany five months previously to join her husband, who was with the army of occupation, and had apparently been infected there. She was treated for syphilis, and had had a negative Wassermann reaction and no clinical signs for two and a half years. In February, 1924, three and a half years after infection, and two months after her last visit to the clinic, she returned complaining of slight frequency of micturition. Vaginal examination revealed an irregular growth of the cervix, which bled readily. She was admitted into hospital, and Miss Nicholson operated a few days later. There was a warty growth arising in the cervical canal, and the microscopical section showed a luxuriant papillomatous growth originating from the columnar epithelium, which did not invade the stroma of the cervix, and therefore might be considered benign. The cells, however, were multi-layered, actively proliferating, and irregular in shape. These facts, in conjunction with the microscopical appearances, were in favour of malignancy. The closed adherent tubes showed that a gonorrhoeal infection was also present, and an interesting fact was that a year afterwards, on resuming marital relations, she developed acute urethritis and vaginitis, gonococci being demonstrated in smears from both orifices. She was at present, two years after operation, alive and well, and apparently free from recurrence.

CASE III.

A woman, aged 50, married for twenty-nine years, had borne one full-time living child twenty-eight years ago, and had had no further pregnancies. She was sent to the venereal department in June, 1925, suffering from tertiary syphilitic ulcers of the thighs, and the Wassermann reaction was positive. Urethritis, vaginitis, and endocervicitis were also discovered, and gonococci were found in the urethral and cervical smears. A subtotal hysterectomy had been performed four years previously. This

patient had had intravenous injections of neokharsivan and local treatment for the gonorrhoeal infection two and a half months. She had ceased to attend the clinic last September, and returned in February, stating she had been suffering from neuritis of the left arm, but had noticed no discharge or haemorrhage. On inserting the speculum to examine the cervix Miss Nicholson saw a small cauliflower-like mass, which bled readily; the microscopical section showed a squamous-celled carcinoma.

Miss Nicholson said that in each of these cases the presence of the gonorrhoeal infection with its accompanying cervical discharge might have been a predisposing factor in the production of cancer. In Cases I and III local treatment might have caused further irritation. It was, of course, a possibility that the primary chancre occurred upon the cervix in these cases, as it was not seen anywhere else. The youth and nulliparity of Case I were unusual with carcinoma, and so made it more probable that venereal infection might have been a factor in this patient.

Hydatid Cyst of Cervix.

Dr. H. LEITH MURRAY (Liverpool) showed a case of hydatid cyst of the cervix uteri. He said that hydatid cysts of the internal genitalia appeared to be very rare. Some, if not most, of the cases recorded were undoubtedly a direct extension to the uterus, Fallopian tubes, or ovaries of an adjacent hydatid tumour. The present case was of interest by reason of its unusual situation, and in its history of a retroperitoneal hydatid cyst removed from the region between the right kidney and the liver eleven years and eight months previously.

The patient was aged 32, married for thirteen years, but without family. She had spent the whole of her life in a village on the estuary of the Dee, and had never been even one night away from home. She did not keep dogs, and had no particular liking for uncooked vegetables. Menstruation was regular at twenty-eight-day intervals, and with a duration of three to four days; the quantity was moderate, but clots were occasionally present. Her symptom in November, 1925, was pain radiating from the left of the umbilicus across the right side to the back. This pain had troubled her for at least ten years, and for the last few years she had felt, when walking, that there was a "big lump" in the pelvis. The pain was less severe now than previously, but the feeling of weight and fullness in the pelvis was increasing. Her previous history of hydatid cyst was as follows. She was admitted to the Hospital for Women, Liverpool, in January, 1914, under Dr. Briggs. Her abdomen was full of ascitic fluid of an opaque shaggy kind, which was tested by inoculation of a guinea-pig and found not to be tuberculous. The explanation came later, after her return home, when a retroperitoneal cyst formed between the right kidney and the liver; this Dr. Briggs had opened from the right loin on March 4th, after her readmission to hospital. The urine was normal, so it was hoped that there was no serious disease in the kidney. The cyst was then found to be hydatid, and whenever a hydatid cyst has burst into the peritoneum, in Dr. Briggs's experience, the daughter cysts had grown all over the abdomen. It never occurred to him that the "ascitic" fluid might be due to the leakage of a hydatid cyst. The experience had been unique. Dr. Briggs also reported that the uterus, tubes, and ovaries were then normal.

Examination of the abdomen in November, 1925, showed a large swelling, the size of a sixteen weeks' pregnancy, extending rather more to the left side than the right. The swelling was dull to percussion; it felt solid and rather fixed. Vaginal examination showed the lower pole of this tumour depressing the vault of the vagina, and rotating the os upwards and forwards so that it lay quite beyond reach behind and above the symphysis pubis. There was a doubtfully cystic area posteriorly, but the main mass of the tumour felt as solid as at abdominal examination. A provisional diagnosis of hydatid cyst in the pelvis was made.

As there appeared no possibility of reasonable access from below, abdominal operation was performed on November 11th; it was at once obvious that the swelling was wholly in the cervix. Kelly's method of approach, by bisection of the small uterine body lying on the top of the swelling, was adopted, and after the abdomen had been thoroughly packed an incision into the cervix was made. A cystic swelling with a thick capsule was at once exposed and opened; it was judged to be rather larger than a full-term foetal head. Very numerous daughter cysts, varying in size from a hen's egg downwards, escaped, and the cyst wall was then, with difficulty, shelled out from the surrounding cervix. Rather to his surprise, after a troublesome dissection, mainly by finger pressure, he succeeded in removing the whole of the capsule in a single piece. There was no sign of any other cyst in the pelvis, abdomen, or kidney regions. It would have been impossible to remove the remaining thin shell of cervix, and the cavity, therefore, was reduced by sutures and a subtotal hysterectomy; both appendages were removed. There could be no doubt that the cyst lay wholly within the substance of the cervix, for a most definite and intact capsule of cervix was visible at the end of the enucleation. Its situation appeared to be in the posterior wall, but the cervical canal was not seen. There were no peritoneal adhesions whatsoever. The patient made an uninterrupted recovery. When seen in a routine way on March 15th, 1926, she complained of some dis-

comfort in the pelvis, and at examination a little thickening, apparently in the recto-vaginal space, was felt; this appeared likely to be inflammatory.

Dr. Leith Murray said that Giles¹ appeared to have recorded the first genuine case of primary hydatid tumour of the uterus occurring in this country. The cyst was the size of a foetal head, and lay definitely in the substance of the anterior uterine wall. He was able to record very few cases from foreign literature. Do Vries, who recorded a case in 1904, found at that time only seven genuine cases in the literature. Tittell² described a uterus the size of an eight months' pregnancy with ovaries each the size of a child's head; all three organs contained an enormous quantity of cysts and hooklets, without evidence of hydatid cyst elsewhere. The present case could not, of course, be compared with those just quoted, except in its suggestion of infection of the uterus through the blood stream rather than the digestive tract.

Cervical Carcinoma of a Prolapsed Uterus.

Dr. Leith Murray also described a case of carcinoma of the cervix of a prolapsed uterus, and said this condition appeared to be surprisingly infrequent. The case now recorded was the only one he had had under his own care, and was the second he had ever seen.

A married woman, aged 43, gave a history of moderate and not very troublesome prolapse for some years. She had had a family of four; the last birth was eight years previously. She had been under treatment for pulmonary tuberculosis for two years, and was considered to be holding her own; she had not recently lost weight. Her cough, however, was troublesome, and to this was attributed an aggravation of the prolapse which had occurred a few weeks before Dr. Murray saw her. During those weeks there became apparent for the first time, so she stated, a protrusion at the vulva, which bled readily and almost continuously, and was associated with considerable pain in the pelvis and a tendency to retention of urine. She asserted that menstruation had been regular, but scanty, until two months previously; since that time there had been a good deal of blood-stained discharge, with latterly an objectionable odour. Examination showed the patient to be thin, but in no sense wasted. At the vulva there was protrusion, about 2½ inches long, of sloughing, infected, friable carcinoma; it bled readily to the touch, and appeared to be freely movable. In view of her tuberculosis and the grossly infected condition of the cervix, it was considered best to recommend a quick amputation of the cervix, followed by radium. On October 20th, 1924, Dr. Leith Murray proceeded to amputate the cervix. The bladder was separated with some difficulty, but was not definitely invaded by the growth; the difficulty appeared to be due to cellulitis resulting from secondary infection. During the operation the peritoneum was accidentally opened, and a vaginal hysterectomy was substituted for the original intention. The patient made a good recovery from the operation, and underwent prophylactic radium treatment. There was no recurrence of vaginal bleeding, but, as Dr. Leith Murray did not have an opportunity of examining the patient after the operation, he was unable to state whether symptomless recurrence developed. She died twenty-one months later, apparently from the lung condition. Sections even of the deepest part of the growth showed intense infection of a very active squamous carcinoma of rather unusual type. Clumps of cells appeared to lie in pseudo-acini, and had in places a margin that might almost be described as "palisade." There was, however, no further resemblance to rodent ulcer, and the type of cell was very different from that found in this disease.

Dr. Leith Murray added that it was interesting that the only case of carcinoma of a prolapsed uterus recorded in the *Journal of Obstetrics and Gynaecology of the British Empire* (Russell Andrews, 1910, vol. 17, p. 234) had a similarly short history of protrusion, although the length of the uterus in that case made it certain that there had been a visible prolapse for some considerable time. In the present case the specimen clearly showed that the cervix itself lay beyond the vulva, and that the protrusion was not merely a proliferative "cauliflower" carcinoma.

Atresia of the Vagina.

Dr. ARTHUR A. GEMMELL (Liverpool) showed a case of congenital absence of the vagina in view of the rarity of the condition in association with full development of the uterus and appendages.

The patient, aged 18, complained that she had never menstruated, but had had periodic attacks of abdominal pain for the past fourteen months. The attacks lasted a fortnight and occurred at monthly intervals. The pain was felt in the sacral and hypogastric regions; it was so severe that it caused vomiting, but

¹ *Proc. Roy. Soc. Med. (Obst. and Gyn., April 6th, 1911).*

² *Arch. f. Gynak., Bd. 82, 1927, p. 180.*

was relieved by hot applications and brandy. The attack in which the patient was seen had lasted two weeks. On examination, she was found to be poorly developed for her age. There were six digits on the right hand and each foot. The secondary sex characteristics were well developed. There was a mass in the abdomen extending from the symphysis pubis to the umbilicus, and the upper part of this felt like the body of the uterus. The external genitals were normal, but what was at first taken to be a vaginal orifice with a hymen proved to be a patulous urethral orifice situated in a more posterior position than normal; there was no vagina. Rectal examination confirmed the absence of vagina, and showed that the lower pole of the mass was cystic and extended to within about 2½ inches of the perineum. It was considered wiser to attempt to reach the retained menstrual fluid from below, and after it had drained away to determine exactly what parts of the sexual apparatus were present before deciding on a final course. Accordingly, a transverse incision was made in the perineum below the urethral orifice, but anterior to the fourchette. Blunt dissection was cautiously performed through moderately firm tissue, the direction being guided by keeping a sound in the urethra and a large dilator in the rectum. Finally, the lower pole of the mass was reached and opened, and menstrual fluid escaped; at this point it was noted that pus escaped from the urethra. A tube was passed along the track formed by dissection, and stitched to the vulva. The patient had been having rises of temperature before the operation, and continued to have them afterwards. A dilator was passed along the track daily, and menstrual fluid escaped with pus on one or two occasions. Five weeks later discharge from the track had ceased; there was still an abdominal swelling half-way up to the umbilicus, but nothing suggestive of a uterine body, and the whole mass was fixed. During this time there had been no menstruation and no attack of pain. On opening the abdomen, the bowels and omentum were found adherent to the abdominal wall and to one another, evidently shutting off the retained blood. These were separated with considerable difficulty, and during the process about an ounce of pus escaped from a pocket in the region of the right appendage. By further dissection the appendages were freed, the right from its normal position, the left from the bottom of the pouch of Douglas. The tubes were found to be distended with blood, and the left open at its fimbrial end. The uterus was enlarged, soft, and retroverted, and below ended abruptly in a firm boss embedded in soft connective tissue. Hysterectomy was performed, but in attempting to enucleate what was thought to be the lower pole of the cervix from its bed it was accidentally cut through, and as the patient was suffering from shock, and all secreting tissue had been removed, no time was lost in completing the operation. Peritonization was carried out in the usual way, but with some difficulty. The dissection from the perineum was found to have opened into the pouch of Douglas, and this was kept open as a drain. On examining the specimen it was found that there was actually a small cap of vagina attached to the uterus. The patient had a somewhat stormy convalescence. Fairly large quantities of pus were discharged from time to time from the perineal sinus which was kept irrigated regularly, but there was never any suggestion of peritonitis. On examination almost four weeks after the abdominal operation, the perineal track was healed and there was a little thickening on the right side of the pelvis. The patient was well and free from pain.

Dr. Gemmell said that absence of the vagina associated with haematometra, with or without haematosalpinges, was a rare condition, and he had been able to trace only fourteen cases in the literature; four of these had been reported by members of the North of England Obstetrical and Gynaecological Society. The commoner condition was complete absence of the genital tract or its presence in such rudimentary form as to preclude menstruation. In seven of these cases hysterectomy was performed immediately; five had an artificial vagina formed, as some part of the vagina persisted; and no post-operative complication was mentioned in any of the twelve. In the remaining two cases perineal drainage was resorted to; one patient died, and the other recovered with suppuration.

Toxaemias of Pregnancy.

Dr. G. W. THORALD (Leeds) reported several cases of toxæmia associated with pregnancy, presenting unusual features. Four of these patients had suffered from severe hyperemesis gravidarum; two died, one delivered herself of triplets at about the sixteenth week of pregnancy, while the fourth improved after induction of labour. He then discussed hyperemesis gravidarum from the theoretical and practical points of view. He argued that every physiological process was for the immediate good of the body, whereas pregnancy, with the eroding action of the trophoblast, the extreme hypertrophy of the uterus, the presence of syncytium in the blood stream, and its many concomitants which were not to the good of the body, could hardly fall within the limits of the physiological. It seemed to him unfair that the vomiting of pregnancy should be considered as a nervous phenomenon, and claimed that

although the vast majority of patients, especially in the early months of pregnancy, could be cured by suitable treatment, yet the underlying cause of all vomiting was the toxin circulating in the pregnant woman's blood. There was apparently no chemical test which was of any value in discriminating between the various cases. From the point of view of treatment, a great difference existed between those cases of excessive vomiting occurring before and those cases occurring after the twenty-eighth week of pregnancy. In the latter group excessive vomiting was usually only one of several manifestations of a toxæmia. He held that menstruation, pregnancy, and labour were normal and natural, but not physiological, and they represented a sacrifice on the part of the woman for the good of the race. Pregnancy lowered the threshold of vomiting, and such occurrences as home worries and constipation precipitated the attack, which of itself set up a vicious circle, both mentally and physically.

Dr. J. E. GEMMELL (Liverpool) showed a specimen of carcinoma of the body of the uterus, Mr. A. LETLAND ROBINSON (Liverpool) showed a specimen of a sessile fibroid polyp causing inversion, and Dr. J. W. A. HUNTER (Derby) a case of acute post-partum oedema of the cervix.

ACUTE PHLEGMONOUS GASTRITIS.

At a pathological meeting of the Liverpool Medical Institution on March 25th, Dr. J. C. M. GYEN, the President, in the chair, Mr. D. R. OWEN read a paper on acute phlegmonous gastritis.

Mr. Owen commenced with a short review of the literature of the subject, including the writings of Rixford, Norak, Sundburg, MacAuley, Berkeley Moynihan, and others. He then described two cases of this disease which he had seen at the David Lewis Northern Hospital, Liverpool, within a few weeks of each other. The first patient, a married woman aged 60, gave a long history of "indigestion." She was operated on for perforated ulcer; the true condition was diagnosed at operation and confirmed at the necropsy, twenty-four hours later. An anterior gastro-enterostomy was performed at the operation with a view to draining the stomach, and abdominal drainage was also provided. The second case was in a male sent in as a perforation case and operated upon for an "acute abdomen." The speaker referred to the presence of a "stomach dullness" area, not previously described; it might be expected in these cases, considering the pathological findings. The condition was recognized at the operation, and, as there was pus in the pelvis, all that was done was to place a drainage tube in the recto-vesical pouch. The abdomen was then closed. At the necropsies a similar condition was found in each case. The stomach was greatly thickened and showed signs of acute inflammation; its cut walls oozed pus. There was an acute cellulitis of the stomach in each case, although there was no sign of recent ulceration, and no cause of the cellulitis was found. In the first case a bacteriological examination was not made, but in the second case a mixed infection of *B. coli* and streptococci was found. Mr. Owen then described the localized and the diffuse types of the disease, showing that his cases belonged to the latter, the so-called "idiopathic" or primary phlegmon of the stomach. He proceeded to discuss the possible sequelae—intra- and extra-gastric perforation, peritonitis, and septicaemia—and then, in considering the etiology, mentioned the American experiments of feeding animals on ground glass and on a mixture of ground glass and streptococci. He also referred to recent work, showing that the normal amount of hydrochloric acid in the stomach was of value in rendering innocuous any germs which might ordinarily enter the stomach with food. Supposing that natural cure took place in some cases, Mr. Owen suggested that a very considerable amount of fibrosis would be found, and he therefore suggested that some of Alexis Thomson's cases of "fibromatosis" of the stomach might have been cases of cured phlegmon of the stomach.

Mr. Owen considered that the ideal treatment of this condition was gastrectomy, but, when seen, his

patients could not have endured such an operation. He therefore advocated the application of general surgical principles, when the condition was recognized after mid-line or right abdominal section, which would be the usual operation performed. The two essentials were to feed the patient and to deal with the cellulitis. He therefore believed in performing a jejunostomy through a new incision to the left—in order to feed the patient and to relieve any distension which might occur—and then proceeding to open the stomach and incising its thick walls to let out the pus. Before opening the stomach it should be fixed to the abdominal wall to prevent infection of the peritoneal cavity. In this situation it could be treated as any other cellulitis would be treated. If serious hæmorrhage were feared, Mr. Owen suggested that the main vessels of the stomach could be secured before making incisions into its walls. In favour of this he argued that further operation would almost certainly be necessary, if the patient recovered, for the removal of adhesions or of a fibrotic stomach, and therefore the cutting off of the gastric blood supply would not be very dangerous. Moreover, as in the past only one or two patients had ever been known to recover, he considered that new, even if heroic, measures were needed.

STERILITY.

At a meeting of the Nottingham Medico-Chirurgical Society held on March 31st, the President, Mr. H. BELL TAWSE, in the chair, Mr. VIERON BONNEY read a paper on the causes of sterility and their treatment.

Speaking of cases of sterility generally, Mr. Bonney said that there were factors which could not be accurately assessed, and others which could. In regard to the former group he quoted the findings of Professor Arthur Robinson, which showed that in animals certainly, and in human beings in all probability, there was a wastage of the ova shed by the ovary, in circumstances favourable for fertilization, of as much as between 40 and 50 per cent. This wastage was brought about in several ways. Some ova never reached the tubes, but were lost in the peritoneal cavity; others, though they reached the tubes, did not blend with a sperm though sperms were there; and others again, though blending with the sperm, perished within a few days of the union, apparently as a result of an inherent deficiency of vitality. There were at present no means of diagnosing such happenings in the case of a sterile woman, nor, indeed, of being sure whether she ever passed fertilizable egg-cells out of her ovary. The factors of the second group comprised the patency of the genital canal from top to bottom, the healthiness of the sperm, its deposition in the vagina, and its ascent therefrom. The patency of the female genital canal was essential, and the recent introduction of tubal inflation had greatly extended their diagnostic capabilities in this connexion. Every woman being examined under an anaesthetic to find out the cause of her sterility should have her tubes inflated, and he was of opinion that if they were found blocked the best course in the majority of cases was immediately to proceed to open the abdomen and to endeavour to overcome the obstruction. This could often be successfully achieved, the most favourable class of case being that in which the abdominal ostia alone were closed as a result of pre-existent inflammation. He demonstrated to the meeting the apparatus he himself had been using. Absolute blockage in the uterine and vaginal segments of the canal was rare, but stenoses were not uncommon in the cervix and at the vaginal orifice. He referred to the good results which so often followed operative dilatation of the cervix. The two upper segments of the genital canal comprised the follicle itself and the space between it and the abdominal ostium, this latter being the peritoneal segment of the canal. Obstructions could occur from non-adhescence of the follicle, or from the intervention of omental or other adhesions in the peritoneal segment. Non-adhescence of the follicle and the abdominal ostium might be cleared away. Mr. Bonney referred to the conservative surgery of the uterus, the tubes, and ovaries as a means of maintaining the capability of pregnancy already existent, or making possible pregnancy which had hitherto

been impossible. He emphasized the propriety of examining the man as well as the woman, and spoke of the phenomenon of *profluvium seminis*, and also of the possibility of the sperms being killed by the vaginal discharge. Nothing much of scientific value was known about this last, and the subject needed investigation, but it was difficult to get anyone to undertake it. In regard to artificial insemination, his own experience had been uniformly disappointing, but where on account of physical deformity the sperm could not be deposited in the upper vagina it was the logical treatment.

The address was discussed by the PRESIDENT and Drs. BUCKLEY, ROBINSON, WATSON, W. R. SMITH, LOCHRANE, and ALLEN.

RADIOTHERAPY.

At a meeting of the Leeds and West Riding Medico-Chirurgical Society on April 9th, the President (Mr. A. L. WHITEHEAD) in the chair, Dr. GEORGE COOPER (Leeds) read a paper on radiotherapy.

Dr. Cooper referred to the rapid progress recently made in this form of treatment, and the importance of the position it now occupied in hospital practice. He defined the position in the spectrum of the various wave-lengths employed—infra-red, ultra-violet, and x rays—and briefly described the apparatus employed for the production of

the striking results obtained in lupus by combined treatment by artificial sunlight and local applications of the Kromayer lamp. He claimed that lupus could now be regarded as a curable disease, and confirmed the reports of other workers as to the very favourable results obtained in the treatment of rickets and of tuberculous lesions by artificial sunlight. Artificial sunlight baths were now being used successfully to hasten recovery in cases of chronic infection. With regard to x-ray treatment, Dr. Cooper claimed that this was still the only agency which exercised a controlling influence over the growth of the cancer cell, and he considered that as only hopeless and inoperable cases were sent to the radiotherapeutic department it could be said that a very fair proportion of cases yielded favourable results. Further progress in x-ray therapy would probably come by the use of some sensitizing agent before, during, or after the x-ray treatment. Dr. Cooper showed a number of cases that had been treated by radiotherapy, including rickets, lupus, tuberculous arthritis, carcinoma of the parotid, thyroid, and mammary glands, carcinoma of the cervix and of the stomach, and sarcoma of the ilium and femur.

Later in the evening Dr. Cooper demonstrated the work of the light department, and various cases were shown being treated by deep x-ray therapy, artificial sunlight, diathermy, and ionization.

Radiography.

Dr. H. B. SEANGILL (Leeds) exhibited a large number of radiographs and lantern slides from the radiographic department of the Leeds General Infirmary representative of the work of the department, and indicated the great increase in the radiographic work of the institution during the last seven years. More than four times the number of patients were radiographed last year as in 1919, and the expansion was still rapidly continuing.

Dr. L. A. ROWDEN (Leeds) demonstrated x-ray photographs of hour-glass stomach, and expressed the opinion that the condition was much less frequently met with than fifteen years previously. In his opinion the condition was sometimes congenital. In the acquired case he had seen a completely healed ulcer, although the opinion generally held was that complete healing was rarely if ever found.

Dr. J. A. THORPSON (Harrogate) demonstrated radiographs in connexion with diseases of the hip-joint met with in spa practice. He also exhibited a series of radiographs of a case of aerophagia in a child of 8 years. The child had chronic intermittent abdominal distension, and the photographs appeared to indicate that the distension was due to swallowed air, which finally passed into the bowel and caused distension of the small and large intestine.

Reviews.

DIGESTION AND GASTRIC DISEASE.

PROFESSOR HUGH MACLEAN, Director of the Clinical Medical Unit at St. Thomas's Hospital, London, who is the editor of the Modern Medical Monographs series, has himself contributed a volume entitled *Modern Views on Digestion and Gastric Disease*.¹ It is a useful unit in this series, and is written in the clear and decisive style which has made Dr. Maclean's former writings so popular. But, compared with his books on renal disease and on diabetes, this monograph on digestion and gastric disease has less to add to what the standard medical textbooks say. In it we have the old wine in slightly renovated wine-skins. The ferment of new knowledge has not so greatly disturbed our views on digestion and gastric disease, and the modern views which Dr. Maclean lucidly expounds do not vary greatly from those of a previous decade. In some particulars, however, the teaching of to-day differs from that received by earlier generations of students, notably on certain phases of the digestive process. Thus, duodenal regurgitation has been found to be a most important event in the course of digestion, and any interference with this backward flow of alkaline fluid into the stomach is known to lead to serious disturbance of health.

Dr. Maclean holds strong views on the subject of the supposed relationship between gastric ulcer and cancer. He regards as totally without foundation the statement that gastric ulcers often undergo malignant changes and are a predisposing cause of cancer. The four tables accompanying these pages which compare the duration of symptoms of patients suffering from cancer with the duration of symptoms of cases of gastric ulcer prove conclusively that in ordinary hospital practice patients with gastric ulcer usually give a history of many months or years of invalidism, whereas patients with gastric cancer have often been ill only for a few weeks, and declare that until lately their digestion has never given them a moment's thought. Dr. Maclean has strong views also on the interpretation of the results of test meals in stomach cancer. Absence of hydrochloric acid and the presence of appreciable amounts of lactic acid in the test meal are, he maintains, an almost invariable rule in carcinoma of the stomach.

The general scope of the book is as follows. The earlier chapters deal with the physiology of digestion and the fractional test meal. These are followed by a chapter on the chief gastric diseases and their symptoms, after which the author deals in turn with gastric and duodenal ulcer, gastritis, and cancer. The chapter on the chemical examination of gastric contents and faeces seems rather misplaced at this stage in the book, but it serves to recapitulate many of the preceding opinions. The ninth chapter, on the radiological examination of the alimentary tract, is excellently illustrated with x-ray photographs, and the last chapter, on the treatment of gastric diseases, gives a fairly complete account of both medicinal and dietetic treatment.

A HANDBOOK OF MIDWIFERY AND GYNAECOLOGY.

DR. THEODORE HAULTAIN has published a *Practical Handbook of Midwifery and Gynaecology*² which, so far as the obstetrical section is concerned, follows the lines of a similar handbook, originally written by his father, the late Dr. Haultain, which attained in its day considerable popularity. In the present volume a synopsis of gynaecology on the same lines has been added, and this certainly tends to make it of greater use for the student public to which it is mainly addressed. Books of this kind must be judged according to the standards of their own class, for which there is unquestionably a definite if small place, mainly in the undergraduate's library. In our view this present volume compares very favourably with other books of its

kind, and will prove of value to students reading for examinations, and more occasionally to practitioners who wish to make a rapid survey of the main facts of any subject.

In looking through the book we have noted one or two points, which may be remarked upon. For example, in connexion with hyperemesis gravidarum, we observe that Dr. Haultain gives considerable space to the reflex variety. This is scarcely in keeping with modern teaching on the subject, and it seems a pity to continue it. Under the symptoms of pre-eclamptic toxæmia there is no mention of epigastric pain, but the treatment of eclampsia is as well described as is possible in such brief space. In regard to the estimation of the date of confinement, it seems unnecessary to complicate the ordinary method with qualifications based on whether or not the month of February is included, or upon whether the year is a leap year or not. The calculation is at the best an approximate one, and the day or two's difference which these points involve is of little practical importance. In the mechanism of labour Dr. Haultain mentions the lever theory as the sole explanation of the increased flexion of the head, regardless of the objections to that theory whilst the membranes are intact. Where the number of illustrations is limited to thirty-six, it seems rather a waste to illustrate Robert's pelvis, which is rarely if ever seen outside a museum, and two pages devoted to the obsolete operations of symphysiotomy and pubiotomy are also extravagant. The discussion of puerperal infection leads the author naturally to the subject of gynaecological infections, and from that he goes right on with the other gynaecological matter. Six and a half pages are devoted to tuberculosis, which, in view of its comparative rarity, seems rather out of proportion.

All these, however, are relatively small matters, and do not affect the general excellence of the subject-matter. The proof-reading might have been a little more carefully done, as the arrangement of headings, and the enumeration of causes, etc., under them are not infrequently confusing. But we can most cordially recommend this little volume to students who require a condensed synopsis for a rapid survey of the subjects.

THE EVOLUTION OF ORTHOPAEDIC SURGERY.

IN 1922 the Detroit Orthopaedic Lectureship was established to "foster orthopaedic surgery at large and in our midst. The lecturo is to be delivered under the auspices of the Wayne County Medical Society, by a man, not necessarily an orthopaedic surgeon"; the subject is to be "cognate to orthopaedic surgery and of broad importance."

Under these conditions the society could not have chosen a better qualified or more appropriate orator for the first lecture than Dr. R. B. OSGOOD of Boston, who is so well known and respected in this country as well as in the United States. Dr. Osgood has printed his lecture in a small book entitled *The Evolution of Orthopaedic Surgery*.³ Dr. Osgood begins by declining the difficult task, which has baffled many others, of defining orthopaedic surgery, and is satisfied to accept the broad limits given by Sir Arthur Keith which ascribes to the specialty the task of effecting "the repair of the mechanical framework of the human body by all operations and appliances which have that aim in view." If we attempt to particularize from this generalization we shall find that it is too wide in some directions and too narrow in others, and we may be driven to the conclusion that orthopaedic surgery can only be defined by stating what it is not—that is to say, that it includes the whole of surgery with the exception of that of the special senses and of the cavities of the body. Even such a definition as Sir Arthur Keith's would have shooed the older generations alike of orthopaedic and of general surgeons.

It is scarcely necessary to say that Dr. Professor Osgood has produced as masterly and complete an account as the space at his disposal would allow. If he has thrown a rather fine net too widely it is an error in the right direction, although some of those surgeons he has included

¹ *Modern Views on Digestion and Gastric Disease*. By Hugh Maclean. M.D., D.Sc., M.R.C.P. Modern Medical Monographs. London: Constable and Co., Ltd. 1925. (Demy 8vo, pp. x + 170; 23 figures, 14 charts. 12s. net.)

² *A Practical Handbook of Midwifery and Gynaecology*. By W. F. Theodore Haultain, O.B.E., M.C., B.A., M.B. Cantab., F.R.C.S.E. London: The Scientific Press (Faber and Gwyer, Ltd.). 1925. (Demy 8vo, pp. xiii + 315; 35 figures. 10s. 6d. net.)

³ *The Evolution of Orthopaedic Surgery*. By Robert Bayley Osgood, A.B., M.D., St. Louis: The C. V. Mosby Company. 1925. (Extra post 8vo, pp. 70; 49 figures.)

would probably have been much surprised to learn that they were orthopaedic. Quite naturally the orator has given full space to the claims of Americans, and perhaps not quite enough to Europeans, but in this matter the relative standpoints of the author and his readers will affect opinion. The omission of the name of William Adams is, however, remarkable. His writings on orthopaedic surgery had a considerable reputation, and his pathological work on the process of repair in tendons after division is of permanent value.

The book is well printed, but, to be candid, we cannot accept the reproductions of portraits as fairly representative of the high standard reached by American photo-engravers and of the country where the half-tone process originated. The portraits of Sir Robert Jones and of Professor Putti are particularly poorly reproduced.

We are inclined to question the claim, which has often been made for Delpech, and often contested, that he originated the method of subcutaneous tenotomy for contracted muscles. His one and only operation, upon which the claim is based, involved two incisions of an inch in length and was followed by months of suppuration and sloughing.

Percival Pott is not only included among orthopaedic surgeons, but Dr. Osgood has conferred the title of "Sir" upon him. He deserved titular honours far more than many recipients of peerages in his day, but the hard fact remains that he died plain "Mr." and not even Professor or Doctor. Further, we are very much surprised to find it stated (on page 47) of another St. Bartholomew's surgeon, Sir James Paget, that he was assistant surgeon to W. J. Little at the Royal Orthopaedic Hospital. They were contemporaries and in later years professional friends, but during the few years of Little's connexion with the Orthopaedic Dispensary (afterwards the Royal Orthopaedic Hospital) Paget was surgeon to the Finsbury Dispensary, but was giving most of his time and energies to morbid anatomy in the medical school of St. Bartholomew's Hospital.

NERVOUS AND MENTAL DISEASES.

We have received Volumes 39 to 42 of the Nervous and Mental Disease Monograph Series.⁴

The Emotions, Morality, and the Brain, by the veteran neurologist C. von MONAKOW, is, as the translators observe, a "fascinating monograph," and it well repays careful study, though the fact that the translation is more or less literal makes it difficult reading. In successive chapters the author discusses the reciprocal influence of sensations and emotions on each other, and the increasing complexity of their organization; the development of the emotions, instincts, and morality; the anatomico-physiological components of the emotions; the pathology of the emotions and the dissolution and resolution of morality. In a brief but interesting concluding chapter he makes some final observations on the struggle to preserve psychic equilibrium and to attain emotional contentment. The philosophic views Professor von Monakow develops at the end of his essay are not new, but they are full of wisdom. He points out that man can never attain a state of permanent satisfaction; full security of position and life, complete peace and contentment, are only possible for brief moments. The prospects of the future which we strive to endow with the emotions of perfection and complete satisfaction are in reality only phantoms. Man strives untiringly but vainly to realize this dream, to which he gives the name of permanent happiness; but at each advance in these successive stages of "happiness in the immediate present" new difficulties arise. An example of this is found in the ceaseless effort of the cultured man to attain a permanent and entirely satisfactory position in life—to conquer a

situation of contentment and the prospect of a peaceful future—often followed by a sudden disillusionment at the very moment when plans long dreamed of have been brought to a happy realization. Persons often find only a small part of the satisfaction they anticipated from a quiet life, and they usually arrive at the conclusion that the real pleasures of a passive and monotonous existence are incomparably less than those of a life of endeavour, even though the latter be filled with cares and anxieties. Thus, the author concludes, the goal which we strive unceasingly to reach as a reward of our endeavours is illusory. It is not the final arrival at this goal which brings true happiness, but the toil and striving toward this goal. The joy of life, the peace of the soul, happiness, do not reside in us as an independent quality; such emotions are only attained by the rational use of our powers, by the wise satisfaction of the instincts and feelings, by the observation of the requirements of morality. The benefits thus arrived at must, however, be conquered anew every day and every hour. It is natural that such philosophic conclusions should arrest the attention of the reader, since they are the outcome of a life of strenuous research in the sphere of neuro-biology and of a wide knowledge of human nature in all its types, both normal and morbid.

The Development of Psycho-analysis, by Drs. S. FERENCZI and OTTO RANK, is a monograph intended primarily for practising psycho-analysts, and is only expected to appeal to those having a knowledge of the subject with which it deals. The authors express the view that there has grown up in psycho-analytic circles an excessive interest in theorizing, and urge the necessity for increased emphasis being laid on its practical or therapeutic aspects. In view of the fact that a complete analysis is only possible for a limited number of patients, the writers suggest the desirability of some simplification of the analytic technique. They feel that a point may be finally reached when other psychotherapeutic methods which have proved themselves useful, such as suggestion and hypnosis, might be combined with psycho-analysis.

Studies in Psychiatry, vol. ii, contains twelve papers read at the New York Psychiatric Society, the contributors being Drs. L. Pierce Clark, Adolph Meyer, P. C. Knapp, C. Macfie Campbell, Charles L. Lambert, M. C. Ashley, and Smith Ely Jelliffe. The work of many of these writers is well known to psychiatrists in this country, and the papers as a whole will be found suggestive and stimulating.

In a monograph on *Psycho-analysis and the Psychic Disorder of General Paralysis*, Drs. S. HOLLOS and S. FERENCZI aim to show that many psychotic manifestations of general paresis, as well as the entire course of this disease, prove themselves not inaccessible to psycho-analytic explanation. That the content of the psychosis in this disorder, as in all other forms of mental disturbance, reflects the personal wishes, hopes, fears, and past experiences of its subject is a matter beyond dispute, and no doubt the constitutional make-up exerts an influence on the clinical picture, but we do not feel that the interpretation of the psychotic productions from the psycho-analytic standpoint materially adds to our understanding of the disease. Frankly, we find the arguments of the authors elusive and unconvincing.

PRICE'S "PRACTICE OF MEDICINE."

A Textbook of the Practice of Medicine, by numerous authors, and edited by Dr. FREDERICK W. PRICE, first appeared in September, 1922. A review of this excellent and comprehensive textbook appeared in our columns of February 17th, 1923. Since then five impressions have been called for, and the work now appears in its second edition.⁵ There have been a few transpositions of articles, and a number of additions. New articles appear on tularaemia, botulism, apical dental infection, clystous diarrhoea, chronic duodenal ileus, and tuberculosis of the kidney. Articles have been also added on the Schick test in diphtheria and the method of producing active immunity, on the Dick test,

⁵ *A Textbook of the Practice of Medicine*. By Various Authors. Edited by Frederick W. Price, M.D., F.R.S.E. Second edition. Oxford Medical Publications. London: H. K. Mulford, Oxford University Press, 1925. (Med. 8vo, pp. xxxv + 1226; 110 figures. 35s. net.)

⁴ Nervous and Mental Disease Monograph Series. Washington and New York: Nervous and Mental Disease Publishing Company, 1925. No. 39—*The Emotions, Morality, and the Brain*. By C. v. Monakow. Translated by Gertrude Barnes, A.B., A.M., and Smith Ely Jelliffe, M.D., Ph.D. (Med. 8vo, pp. 95. 2 dollars.) No. 40—*The Development of Psycho-analysis*. By Dr. S. Ferenczi and Dr. Otto Rank. Authorized English translation by the New York Psycho-analytic Society. (Med. 8vo, pp. 68. 2 dollars.) No. 41—*Studies in Psychiatry*. Vol. II. By Members of the New York Psycho-analytic Society. (Med. 8vo, pp. 233. 3 dollars.) No. 42—*Psycho-analysis and the Psychic Disorder of General Paralysis*. By Stefan Ferenczi and S. Ferenczi. Authorized English translation by Gertrude Barnes and Gunther Kell. (Med. 8vo, pp. 48. 1.50 dollars.)

in scarlet fever, on the investigation of diseases of the liver and pancreas, on quinidine therapy, on the pathology of auricular fibrillation and auricular flutter, on mental sequelae of encephalitis lethargica, and on parapneumonia. Many articles have been entirely or largely rewritten. These include: the pathology of scarlet fever, diabetes mellitus, secretory disorders of the stomach, diverticulosis, Hirschsprung's disease, cholecystitis, aphasia and other speech defects, epilepsy, hysteria, neurasthenia, and dystrophia myotonica.

The whole book has been brought thoroughly up to date, and we can again cordially recommend it. The publishers are to be congratulated on the way in which they have produced it; the type is clear and the thin paper selected quite good. Although the volume contains nearly 2,000 pages, including the index, it is not unwieldy.

ANNALS OF MEDICAL HISTORY.

THE first or spring number of the eighth volume of the *Annals of Medical History*⁶ bears on the outside of the cover, which alters with each issue and is related to the subject of one of the contained articles, a portrait of Galen to illustrate a revised version of Dr. Archibald Macleod's essay—written at McGill fifteen years ago, and read two years ago to the Ottawa Medico-Chirurgical Society—on Claudius Galen. In an attractive article entitled "Some humble workers in the cause of anatomy a hundred years ago," Dr. W. B. Howell recalls the doings of the resurrectionists, body snatchers, or "resurgam homos," whom Sir Astley Cooper described as "belonging to the lowest dregs of degradation." The by-paths of medical men in two rather different directions—namely, as pirates and buccaners and as writers of verse—are dealt with in separate articles by Dr. Leo Eloesser of San Francisco and Sir Humphry Rolleston; among the pirate and buccanier doctors one of the gentlest, most whimsical and engaging was Lionel Wafer at the end of the seventeenth century; the account of him given by John Masefield in his appendix to the edition of *Dampier's Voyages* is reproduced in full. His colleague Esquemeling has left an admirable account of *The Buccaneers of America* (1684), from which much of the article is illustrated; he is described as "a quiet, kindly man, speaking ill of no one," and was obviously a contrast to other surgeons on buccanier voyages. Three studies on "palaeopathology" from Dr. Roy L. Moodie of Chicago deal with a prehistoric surgical bandage from Peru, excessive callus following fracture of the forefoot in a cretaceous dinosaur, and spondylitis deformans in a crocodile from the Pleistocene period. In a brief note Dr. Bernard E. Read gleams from Chinese medicine some queer details on pulse feeling and methods of treatment. Among the editor's reviews, that of *Monumenta Medica*, containing contributions of a notable character from Dr. Charles Singer, may be mentioned as adding to the value of this instalment of the *Annals*.

NOTES ON BOOKS.

THE fifth of the statistical handbooks issued by the Health Section of the League of Nations contains the official vital statistics of the Republic of Austria,⁷ which occupies 32,396 English square miles and contains six and a half million people. This handbook was prepared by Dr. Major Greenwood and Major P. Grauvillo Edge, and includes, in particular, valuable information about infantile mortality and tuberculosis. Since the end of the eighteenth century Austrian official statistical reports have been of a high standard, owing to their recognition as a branch of university education, and also to their study being regarded as a section of statecraft. The statistics of the old empire covered a wide diversity of conditions related to the etiology of tuberculosis; and the effects of war conditions upon its incidence have been more fully reported in Austria than in any other Central European country. Other handbooks are

to be published dealing with the States formed out of the old empire, and the present volume has a special value in that it contains tables of the vital statistics of these States before they commenced independent existence. In the preparation of the handbook the files of the official journal, *Statistische Monatsschrift*, from 1884 to 1914, and 1919-20, have been examined, and notes of memoirs of special interest to the medical statistician are included. The present publication will be found very useful by all students of public health conditions in Central Europe.

Chininum: Scriptioes Collectae Anno MCMXXIV editae is a collection of translations of papers published about quinine in the year 1924. It is issued by the Bureau for Increasing the Use of Quinine, Amsterdam, and is distributed free to pharmacologists and others thought likely by the bureau to further its aim. A collection of the papers which appeared in 1923 and the interest which this first volume aroused encouraged the bureau to publish a second collection. This contains English translations and abstracts of about fifty papers describing the use of quinine for the most varied purposes. Certain of the papers which give an account of the use of quinine in combating malaria epidemics are of interest. Thus Professor Swellengrebel recalls the work of the Malaria Commission of the League of Nations, which travelled through Italy and Eastern Europe and studied the local conditions with a view to determining the most profitable methods of combating the malaria epidemic which has swept over many countries since the war. Their object was to determine the best and cheapest methods for combating epidemics and for eradicating the disease in its chronic endemic form. The latter problem is particularly complex, for the reasons which have caused malaria to disappear from certain districts, such as the Fens in England, have not been fully ascertained. The author suggests that numerous causes must have been at work. The value of prophylactic quinine and of drainage is of course recognized, but in addition he holds that the prevalence of malaria is influenced by the condition of housing and of nutrition of the inhabitants. Apparently when a population becomes rich and well fed and not overcrowded malaria tends to decrease. Emphasis is laid on the fact that there is no single sovereign remedy for malaria, but that the local conditions in each country must be studied and that the preventive measures chosen must be adapted to these local conditions. Dr. van der Spek, who contributes an article on the antimalarial campaign during recent years, quotes figures showing the post-war incidence of malaria. The worst figures are from Russia, where five and a half million cases were reported in both 1923 and 1924, a figure which is double the pre-war rate. This article is illustrated with numerous excellent photographs and concludes with full-page reproductions of twelve posters used in antimalarial campaigns in Europe, America, and Asia. Besides the papers dealing with the action of quinine in malaria the volume contains others describing its use in a large variety of conditions. Several papers deal with the action of quinine in inducing or hastening labour and others describe its use in surgery both as a local anaesthetic and for the treatment of varicose veins and haemorrhoids. The volume will be found useful by all specially interested in quinine; the excellent illustrations, which show many phases of antimalarial work in different countries, deserve special mention.

The Department of Pathology of Columbia University, New York, publishes at regular intervals bound volumes of reprints of scientific articles contributed to various scientific journals by investigators holding official appointments in the university, and also by volunteer workers in its laboratories. This plan of collecting and publishing in one volume the research of an institution is useful, particularly in such a case as this, where a large proportion of the research work is focused on one subject. The twenty-six articles in vol. xviii were mostly devoted to rickets, and many of the forty-nine articles in vol. xix deal with the same disease.⁸ Drs. J. W. Jobling, A. F. Hess, and A. M. Pappenheim have contributed numerous papers to each volume. The scope of this research is very extensive, and includes experimental work on laboratory animals, biochemical investigations, dietary studies, and experiments in protective radiation. Dr. Hess's work on the chemical changes which take place in the blood of irradiated animals and the remarkable effect of radiation of certain foods in hestowing on them antirachitic factors is well known in this country. We have drawn attention to many of the new ideas which have emanated from the Columbia school in annotations and

reviews of published work. The subject was fully discussed in two of the sectional meetings at Bath and reported in this JOURNAL (September 12th, 1925, pp. 470-477; September 19th, pp. 499-503). Therefore it is not necessary to do more than announce that these original papers have been received and placed in the Association Library, where they are available for consultation in the handy form which this system of binding together the writings of one school ensures. Papers on other pathological problems are included in both volumes, these also being reprints from scientific journals.

MEDICAL AND SURGICAL APPLIANCES.

A Manometric Lumbar Puncture Needle.

DR. J. G. GREENFIELD (Pathologist to the National Hospital, Queen Square, for the relief and cure of diseases of the nervous system, including paralysis and epilepsy) writes:

That the pressure of the cerebro-spinal fluid is not measured in this country as often as it should be appears to be due chiefly to the difficulty of doing this single-handed with the apparatus at present on the market. These all consist of attachments which are fitted into the lumbar puncture needle after the fluid has begun to flow. This has several disadvantages. One is the fact that only one hand is available to withdraw the stylet and pick up and attach the manometer, the other hand being engaged in steadying the lumbar puncture needle and holding a tube to collect the fluid that escapes in the interval. Another disadvantage is that slight movement of the needle in or out during the process of attaching the manometer may displace the point so that the flow of fluid ceases. To obviate these disadvantages I have had a lumbar puncture needle made for me in which a three-way cock and a side tube for the manometer are incorporated in the handle with very little increase in weight.

In using this needle the manometer, whether of the glass tube or the aneroid variety, is attached by rubber tubing to the needle as soon as it is felt to have entered the spinal canal. Then, while one hand holds the needle in place, the other simply removes the stylet and, if fluid appears, turns the stop-cock through a quarter circle in the direction of the manometer tube. (Position D.) When the pressure and pulsation of the fluid have been noted a turn of the tap towards the handle of the needle (Position B) allows the fluid to run out of the manometer into the collecting tube, and also allows further flow of fluid from the spinal canal. When the tap is turned away from the manometer (Position A) the manometer empties itself but the spinal canal is shut off. If it is desired to inject anything into the spinal canal the tap may be turned towards the point of the needle, so that the manometer is shut off (Position C), but it may be thought better to leave the manometer tube open, so that the injection pressure may be gauged and controlled. The forward position of the tap may also be used for replacing fluid with air.

It is advisable to sterilize the needle with the stylet out and with the tap turned towards the handle (Position B), as in that position water passes freely into the manometer tube from the inside of the needle. In the figure a glass manometer is shown, provided with two sliding clips, by which the initial and final levels of the fluid can be marked and read after the operation is completed.

Messrs. Allen and Hanburys, Ltd., of 43, Wigmore Street, London, W.1, are the makers.

SMALL-POX IN AUSTRALIA.

DR. J. H. L. CUMPTON, Director-General of Health and Director of Quarantine, and Dr. F. MacCallum, Quarantine Officer, Commonwealth Department of Health, have written a history of small-pox in Australia from 1909 to 1923, and the work has been issued under the authority of the Minister of Health.¹ The book is a sequel to a volume dealing with the same subject for the period 1788 to 1908. Dr. Cumpston is of opinion that the special aspects of the epidemiology of the disease as it has shown itself in recent years in Australia and in small-pox infected vessels on their way to Australia are the short range of infection, the comparatively low degree of infectivity, the irregular incidence of attack under equal exposure, and anomalies as to vaccination immunity. The scheme of the book includes a history in considerable detail of successive outbreaks in each State within the Commonwealth, and gives the story of its introduction by individual vessels, and of quarantine and vaccination measures adopted for its control. The record is, indeed, so full that the reader can in large measure study for himself the epidemiology of variola both on board ship and in the various provinces.

As to the amount of vaccination in Australia as a whole, it was approximately estimated in 1910 that some 30 per cent. of all persons had been vaccinated, and the authors think that, taking account of troops returned from war service, the same rough estimate of 30 per cent. may still apply, the community being normally free from small-pox and largely without compulsory infantile vaccination. As now in this country, the amount of vaccination done from year to year seems to depend largely on the prevalence of small-pox. In New South Wales only 11 of 43,782 births in 1909 were vaccinated, but in 1913 there was a small-pox outbreak, and the public vaccinators recorded over 10,000 vaccinations, while the authors, in a footnote, explain (pp. 78 and 99) that probably 500,000 were really vaccinated in New South Wales itself, and the same outbreak resulted in the adjoining State of Victoria having 150,000 vaccinations of adults. It is observed that no attack occurred in a vaccinated person under 20 years of age, or in any person vaccinated within thirteen years previous to attack. No case occurred in the New South Wales outbreak among any of the staff of the Commonwealth Quarantine Service or the State Health Department, excepting one disinfecter on the staff of the latter who by some means evaded vaccination. Regarding the value of vaccination as a community measure in Australia, it had been suggested in the previous report that the conditions essential for an epidemic were (1) the virus, (2) susceptible population, and (3) a third factor or factors not understood. Hypothetically the third factor was regarded as a short range of infectivity in a community not sufficiently aggregated to let the disease spread so rapidly as to become uncontrollable. The authors hold that the experience of the past fifteen years supports this interesting hypothesis. In the course of the volume much detailed information is given as to variation in the duration of the incubation period, the invasion period, and the escape of exposed persons from infection even on shipboard with limited accommodation. Voyages to Australia from many ports are accomplished well within the incubation period of small-pox, and in the time under review eighty-nine vessels had to be quarantined, as against fifty vessels in the fifteen years 1879-93, and the same number in the next fifteen years, 1894-1908.

It is regrettable that a work whose value for reference largely depends on the detailed information with which it is packed should have been issued without a reference index. Also the table of contents at the beginning is irritatingly inaccurate. The book has fifteen chapters, and for thirteen of the fifteen the page reference is incorrectly stated, so that a reviewer has to start by making a paging of his own. Notwithstanding this slip in passing the sheets through the press, the report is an important and valuable contribution to the literature of small-pox, and will no doubt be studied by the committees set up by the League of Nations and by our own Government.

¹ Service Publication No. 29. Melbourne: H. J. Green, Government Printer. 1925. (8½ x 6, pp. 243. Paper covers.)

Nova et Vetera.

DR. DAVID KINLOCH (KYNALOCCHUS), 1559-1617.

By the courtesy of Mrs. Lingard-Guthrie, Carnoustie House, Forfarshire, the portrait of Dr. Kinloch has been made available for publication, and since to Sir Norman Moore and Dr. Charles L. Dana little seems to have been

DAVID KINLOCH (KYNALOCCHUS), M.D., DUNDEE, 1559-1617.
1614 portrait in Carnoustie House (Mrs. Lingard-Guthrie).

known about Kinloch save his authorship of Latin verse, it may be of interest to add a few notes. The verses were published in Paris in 1596, and reprinted in *Delitiae Poetarum Scotorum* in 1637, and the first book, *De Hominis Procreatione*, makes Kinloch the first Scottish writer on obstetrics. He was born in Dundee, where his tomb is still extant. He was "incorporated" at the university in St. Andrews in 1576, but did not graduate. In 1596 he was M.D., probably of Paris, where he was well known as devoted to the study of anatomy, and tradition has it that he was called to give medical service at the Court.

In 1602 he was entered as Burgess of Dundee by right of his father John, and in the Roll he is described as "Medicinae doctor Regius." This, or a synonymous term, is used in most of the official records up to an entry in the Registry of the Great Seal in 1616, when he was granted the right of barony in the estate of Aberbothrie, which he had purchased. Sir George Kinloch, Bt., of that ilk is a direct descendant in the eighth generation. Kinloch travelled much, and even two months before his death in 1617 received permission to go out of the kingdom. On one journey in Spain he was seized by the Inquisition and condemned to auto-da-fé. Tradition again has it that when the execution was delayed he made inquiry and was informed that the Grand Inquisitor was ill and he must wait. Making use of a friendly black cat to bear his message he made known his status and offered his service. This was accepted, the Grand Inquisitor recovered, and Kinloch was sent home to illuminate his native land.

In Dundee he married Grizel Hay of Gourdie, and the records show them to have been a high-minded and

humorous pair. There is some suggestion of an attempted encroachment in these entries. At the town council on July 17th, 1610, three masons appeared and confessed "that before sunrising at the command of Griseld Hay, the spouse of Dr. David" they built a pillar of stone work. They were ordered to pay a fine of five pounds and to be punished in their persons in the sight of the bailies and "to demolish the said pillar to the ground and restore the common gait and passage to the auld estate." On August 16th William Ferguson and Walter Rollok, bailies of Dundee, appeared before the Privy Council to answer the complaint of Dr. Kinloch touching their "allegit convocating of his Majesties leigis and casting down of a prettio piller of stone work" which had been erected by the said Mr. David on his own heritage "for setting thairon of his banefire" on August 5th and November 5th in token of his exceeding joy for his Majesties preservation on the said days, and touching the pursuing of the said Mr. David's sponso for her life and the holding of a "whinger" to her breast. Dr. David was present but did not pursue his complaint. In 1613 James Baldavie complained to the Privy Council that his ward had been abducted by Johnne Ramsay, but Margaret gave evidence that of "hir awne propir will and motive" she left James and came directlie to Doctor Kinloche in Dundee "her friend," and that she intended to marry Johnne, and the lords decided in favour of the said Margaret.

Of Kinloch's verse it is enough here to say that the text of the two books is in excellent hexameters which are so closely modelled after Lucretius that phrases or more are borrowed. That Kinloch was not only learned but witty is shown by the epigram dedicating his second book to the Senato of Armorice Gaul which is thus Englished:

Through Eunomis and Panace
Whom Jupiter and Apollo sway
Judge Themis governs judges two
Who all men's rights and weal review;
One judges pleas and one disease
Each measuring in her own degrees:
In function Law and Leech agree
And in the public need unite;
To fortunes you, to bodies we,
Restore their pristine health and might.
So Senators, from Kinloch's hand,
Take these few sprays from Medicine's field,
Which knowledge of our inner ills,
Their sites, signs, causes briefly yield.
Our Faculty's unhonoured till
It be illustred with your skill.
A green old age, Fate grant us each,
Me, without law, you, without leech!

The portrait, dated 1614, precedes by six years the work of George Jameson, the first known Scottish portrait painter. It may not have been painted in Scotland. Some

TOMB OF DR. DAVID KINLOCH IN THE HOWFF, DUNDEE.

of the details are curiously accurate. The text of the first aphorism is legible, and the Latin version is unusual. Perhaps some scholar may identify the edition. Verification of Kinloch's graduation and of his Court appointments in France and Scotland would be useful.

R. C. BUIST.

British Medical Journal.

SATURDAY, MAY 1ST, 1926.

SYPHILIS AND PAROXYSMAL HAEMOGLOBINURIA.

UNTIL the middle of the first decade of this century paroxysmal haemoglobinuria was held to be due to a condition of abnormal vulnerability of the red blood corpuscles to mechanical injury. This fragility, it was supposed, rendered the red corpuscles unable to withstand the vascular commotion which occurred in the peripheral vessels as a characteristically extreme response when the affected individual was exposed to a low external temperature or to severe physical strain. Thus the "attack" of haemoglobinuria and the "interval" were respectively explained by the presence or absence of causes of abnormally severe vasomotor disturbance, capable, it was supposed, of bringing about mechanical injury to the red corpuscles. This alleged vulnerability to mechanical injury, in some instances, appeared to develop in the wake of various infectious diseases, and it was recognized that the initial attack occurred with special frequency after luetic infection. Reasons connected with alleged causes and with apparent differences in nature of attacks suggested, however, that the term "paroxysmal haemoglobinuria" included various clinical and possibly pathological forms that were not sharply differentiated.

The literature of paroxysmal haemoglobinuria during the past twenty years shows that we have during this period discarded the theory of undue fragility of the red blood corpuscles to mechanical injury. This theory vanished because it became superfluous precisely for that form of paroxysmal haemoglobinuria to which Chrostek had specially applied it. As the theory and methods of Ehrlich in the domain of experimental immunology and haemolysis became more widely known, the hypothesis that a haemolytic agent was present in the blood plasma of haemoglobinurics was evolved and put to the test of adequately controlled investigations. By appropriate adaptation of the Ehrlich technique, the presence of a haemolytic amboceptor in the blood of individuals suffering from paroxysmal haemoglobinuria *a frigore* was proved independently by workers in Vienna and this country. The unique character of this haemolytic amboceptor was shown to be that its function of sensitizing either healthy red cells or those obtained from an affected individual was performed only during a period when the mixture of cells and serum containing the amboceptor was kept below blood temperature. Thereafter the haemolytic action rapidly occurred at blood temperature in the presence of complement. These observations, constituting the Eason-Donath-Landsteiner reaction, became the fundamental basis of the pathology of paroxysmal haemoglobinuria *a frigore* (Kälte-hämoglobinurie); the reaction, moreover, was shown to be applicable as a clinical method by which this type could be sharply and certainly differentiated from other forms of haemoglobinuria. The application of this test made possible for the first time a precise diagnosis of the *a frigore* cases, and has thus given a reliability to published records from which a more exact picture of the nature of the "attack" can be drawn.

Briefly stated, the attack is an abnormal reaction towards cold characterized by a haemoclastic crisis in the form of a high grade short-lived leucopenia, by a fall in the blood pressure and body temperature, and by changes in the mode of blood coagulation; secondary to this, and approximately simultaneous with the haemoglobinuric attack, came leucocytosis, and rise of blood pressure, pulse rate, and body temperature. While the haemolysin reaction *in vitro* is the decisive diagnostic fact, it was soon learned that in not a few metallic cases of paralysis this haemolysin reaction was obtained although such individuals had not suffered from attacks of paroxysmal haemoglobinuria *a frigore*. These individuals have been designated "haemolysin carriers," and their condition described as latent haemoglobinuria, and experimental exposure to severe chilling has actually provoked a characteristic attack of haemoglobinuria.

In both "manifest" haemoglobinurics and in latent carriers, blood dissolution is the function of the haemolysin (Kälte-hämolysin), although in the carriers the clinical symptoms of haemoglobinuria have not occurred spontaneously. Many authors, nevertheless, cited the existence of haemolysin carriers as a bar to the acceptance of the haemolytic amboceptor theory of the pathology of manifest paroxysmal haemoglobinuria *a frigore*. Complete confusion thus arose both as to the genesis of the manifest disease and as to its definition as a clinical entity. The difficulty, such as it was, has been bridged in recent articles¹ by Salén of Stockholm, as he finds that in haemolysin carriers an insignificant drop of the blood temperature actually causes the intravital sensitizing mechanism to function, although there are neither external symptoms nor haemolytic and haemoclastic crises. The evidence of the blood-dissolving function in these is the demonstrable reduction in the number of red cells and the prolonged increase of the urobilin of the urine after exposure of a carrier to chilling. This is not altogether a new fact, but Salén goes further, and asserts that the usual method of function of the haemolysin, both in manifest cases and in carriers, is by the extravascular destruction of the red cells already sensitized in the blood stream, as in haemolytic icterus. On the other hand, the haemolytic and haemoclastic crises, as well as the clinical symptoms of an attack, are the expression of a less regular method of function completed intravascularly. It is not our intention to express any definite approval or rejection of this conception, though there are many reasons for accepting it as a probable, though incomplete, explanation for the presence or absence of external evidence of blood dissolution in the form of haemoglobinuria. At all events, it is known that the manifest case may become a latent carrier, and that excessive chilling of a carrier may provoke in him a typical haemoglobinuric attack. Thus Salén comes to believe that the manifest cases and the latent haemolysin carriers can be grouped as a pathological unity.

What is the relationship of syphilis to this group? In one respect the answer is not in dispute, haemolysin carriers being found in about 10 per cent. of individuals showing evidence of tertiary syphilis or suffering from metasymphilitic disease. In many of these, especially metasymphilitics, the haemolysin is a cause of anaemia, although Salén expresses no opinion either regarding this or the relationship of the haemolysin to the various forms of anaemia occurring in syphilis. Reference may be made to the discussion on

¹ Acta Medica Scandinavica, vol. lxi, p. 521 et seq.

visceral syphilis in the Section of Medicine at the Annual Meeting of the British Medical Association at Newcastle in 1921, and especially to the paper on the anaemias of syphilis by Dr. John Eason of Edinburgh (BRITISH MEDICAL JOURNAL, August 6th, 1921, p. 186).

With regard to manifest paroxysmal haemoglobinuria *a frigore*, most authors since 1904 reckon syphilis either as a very frequent cause or the usual cause. That it is a frequent cause has been recognized since the early eighties of last century, and the anti-syphilitic treatment then available was apparently the means of causing disappearance of attacks for as many as seven and eight years. The expectation that more constant good results would be obtained from the new autisyphilitic methods of treatment has been in great measure unfulfilled. Energetic treatment may convert the manifest haemoglobinuria into the latent carrier, but no proof has been obtained that the auto-sensitizing power of the blood, characteristic of this disease, can be abolished by such treatment. The haemolysin reaction remains positive, and definite cure is therefore so far unknown. If, therefore, paroxysmal haemoglobinuria *a frigore* is a post-syphilitic disease, it behaves towards treatment like metallic affections, while the symptoms of tertiary syphilis present are banished.

In his effort to make clear the etiological relationship between syphilis and paroxysmal haemoglobinuria *a frigore*, Salén has wisely restricted his most careful study to the period beginning after 1904. It is not here possible to follow step by step his searching analysis of the cases, 116 in number, collected by him. His final decision that 97 per cent. have had lues or hereditary lues is a valuable contribution to our knowledge, although the close approximation of his finding to 100 is well expected by those familiar with English writings on the subject. Salén seems, indeed, to be overcautious in concluding that it is for the future to decide if manifest haemoglobinuria *a frigore* is to be enrolled among the syphilitic diseases. In the small percentage of cases which he has not included as luetic no other acceptable etiology can be deduced from the recorded facts, and Salén refers to the difficulty of excluding with certainty a diagnosis of syphilis by clinical means. There are many important facts bearing on the etiological relationship of syphilis to paroxysmal haemoglobinuria *a frigore* which are brought out in Salén's analysis, but we will only mention that in all cases in which evidence of syphilis is found the haemoglobinuria is never primary. Salén reveals in detail the errors of Burmeister's statistical methods which led him in 1921 to conclude that only about 30 per cent. of the cases were syphilitic from the anamnetic and clinical facts, excluding the Wassermann test. Burmeister had explained the discrepancy between this figure and the 90 per cent. which gave a positive Wassermann reaction by assuming that the Wassermann reaction in this disease was usually not caused by syphilis, and was, in fact, a non-specific reaction probably due to the "Kälte-amoceptors" in the blood. In support of this hypothesis Burmeister cited certain experiments made by him, which he believed gave proof that the Wassermann reaction was a more sensitive indicator for the presence of the haemolytic amoceptors than the haemolysin reaction. Salén now gives the results of a most elaborately controlled series of experiments in which he has avoided certain defects in Burmeister's work, and the conclusions to which he has come seem to be as completely proved as is within the capacity of a single observer. Salén finds that the haemolytic

amoceptor content of the blood serum has no influence on the Wassermann reaction, and normal salt solution containing amoceptors dissociated at blood temperature does not give a positive Wassermann reaction. Such experimental results are in full agreement with the facts concerning many cases in the literature, in which a strong positive Eason-Donath-Landsteiner reaction has been obtained while the Wassermann reaction of the blood has been entirely negative, or others in which a strongly positive Wassermann reaction has been given by both blood and cerebro-spinal fluid while only the blood gave the haemolysin reaction; and lastly, that in several cases antiluetic treatment has changed the positive Wassermann reaction to a negative without any demonstrable change in the intensity of the haemolysin reaction.

THE COLONIAL MEDICAL SERVICE.

In a leading article on April 10th we called attention to the withdrawal from the BRITISH MEDICAL JOURNAL of the "Important Notice" covering appointments throughout the Colonial Medical Service. In doing so we expressed the hope that certain grave issues raised in the course of conversations between the Colonial Office and the British Medical Association might be brought to a satisfactory settlement before the general efficiency of the service as a whole had in any way suffered from the existing state of affairs. To-day we are glad to announce that such a settlement has been secured. Mr. Amery has, as we have already pointed out, amply vindicated the sanctity of service agreements by the action he has taken in East Africa to safeguard the rights of the existing personnel of the Medical Service under the new Code of Regulations. Beyond this, he has met the several requests contained in a memorial presented by the medical officers of Kenya in a manner which shows a very real desire to satisfy the wishes of the officers concerned as to the conditions under which they are required to work, and encourages the belief that grievances thus indicated and requests made will be accorded full consideration.

Finally, as may be seen from the terms of the correspondence between the Colonial Office and the Dominions Committee, which is published in the SUPPLEMENT this week (p. 175), the Secretary of State has cordially welcomed the prospect of discussions between the Association and his department, and, in addition, while reserving the principle that Colonial medical officers, like others, should in the first place make use of the ordinary official means of making representations to the Secretary of State, he has recognized the claim of the Association to represent the interests of its members throughout the Colonial Medical Services. In a letter from the Colonial Office, to which, fortunately, no further reference need now be made, that claim seemed to be called in question. Experience shows that such discussions, conducted informally and confidentially, and whenever possible before the final promulgation of orders involving substantial adjustments in service conditions, are the best means of avoiding difficulties and friction. An opportunity to deal with the East African Medical Service Regulations in this manner might well, as Mr. Strachey's letter suggests, have prevented the creation of the difficulties and misunderstandings now happily at an end.

Mr. Amery, by strengthening confidence in the sanctity of service agreements, has now cleared the way to that advance throughout the Colonial Medical Service which we believe it to be his sincere desire to

promote by every means in his power. We already owe to him the fine conception of the Colonial Office as an Imperial Ministry of Health. In the task of bringing that idea to fruition he may depend, as we have already pointed out, on the cordial co-operation of the Association, which has consistently laboured to establish such conditions as shall make for the efficiency of the Colonial Medical Service in general, and to that end is prepared, now as in the past, to place at the Minister's disposal experience derived from a membership which covers the whole of the Dependencies for the health of which he is ultimately responsible.

Not the least of the difficulties with which a Secretary of State has to contend in this connexion is involved in the constitutional and economic position of the various Colonial administrations. It would perhaps be true to say that where the need for an efficient medical service—adequately staffed, well organized, and with generous material resources at its disposal—is to-day most clamant, it is too often least realized. For this reason a service which should offer to a medical practitioner of energy and imagination a particularly attractive career is in many Colonies understaffed and not fully effective, whether because the health policy of the individual Colonial administration concerned is not yet adequately developed, or because sufficient funds are not available for putting into effect a policy already agreed upon, or again because for some other reason service conditions are not conducive to efficiency or to economic well-being. Our criticism in this respect is not based upon any academic standard of perfection. It arises from consideration of the actual achievements of the Colonial Medical Service where it has worked or is working under relatively favourable conditions, and a keen desire to secure the removal of the defects which make it impossible at present to recommend certain branches of the service—notably those in the Windward Islands and Malaya—as offering adequate prospects to the potential candidate for appointment. We are convinced that once the necessities of the situation are realized by the Colonial administrations the means to secure the desired end will not long be lacking.

THE BUDGET.

In the years which immediately followed the close of the war financial critics used to refer more or less optimistically to the time when we could return to a "normal" Budget. There seems to be good ground for thinking that we reached the post-war "normal" state of affairs without recognizing the fact, for with a total national expenditure which offers a most obstinate resistance to any reduction below the £800,000,000 standard it looks as if the supernormal has become the normal, and few critics are so sanguine as to expect any considerable reduction in taxation during the next few years. Hopes of a further decline in expenditure have been so often deferred that such expectations of relief as may have survived are centred rather on the possibilities of receipts from our national debtors on the Continent or of the discovery of new forms of taxation which will not cause undue hardship or irritation. The task of a Chancellor of the Exchequer in such circumstances is obviously one of extreme difficulty—certainly one which does not need the additional complication arising out of the £19,000,000 coal subsidy; it requires the employment of the best brains and the greatest industry and zeal at the command of the nation. Fortunately that necessity has been realized

in this country for generations, and few nations, if any, can boast of so able a line of financial ministers as our own.

A brief report of Mr. Churchill's statement is published elsewhere in this issue; here it must suffice to comment on one or two of the outstanding features of this, his second, Budget. On the important question of trade prospects Mr. Churchill sounded a note of subdued hope; the basic industries which provide employment for large masses of workers are still depressed, but he claimed that the country as a whole is better off than it was twelve months ago. That the present Chancellor has a penchant for the striking or even the spectacular has passed into general acceptance; on this occasion he showed that he is not above emphasizing the obvious if he thinks it necessary. The importance he attaches to the settlement of the coal dispute could be seen throughout his speech. He referred to it in his opening remarks, it was the background of his presentment of the need for cautious finance and the exercise of self-denial in the face of any surplus that might be anticipated for the forthcoming year, and before he closed he had proposed to increase this year's sinking fund contribution to repair the effect of last year's raid, and had stated that a prolonged paralysis in industry would necessitate an increase both in direct and in indirect taxation.

On the whole the lines of the Budget follow general anticipation. The betting tax is to be 5 per cent. on all legal bets, to be collected from the bookmaker, who is expected to recoup himself at the backer's expense. It is not unlikely that this proposal will arouse opposition from very different quarters, and until practical experience is available its probable yield must be distinctly speculative; the official estimate is £1,500,000 for the period November to April, and £6,000,000 in 1927-28. The treatment of the motor taxation receipts is undoubtedly a very debatable matter, though evidently in the mind of the Cabinet the present plight of the taxpayer and the great change in circumstances which has taken place since the existing arrangement with regard to the Road Fund have carried the day. Under the Budget proposal the Road Fund will take in future all the yield from commercial motors and hackney traffic and two-thirds of that from private cars. Probably most of our readers will agree that this is all that the country can at present afford to apply to road expenditure from that source. At the same time, the importance of improving the roads can hardly be overrated, and the allotment of £500,000, in addition to the £750,000 already promised for rural "unclassified" roads—welcome as, of course, it is—will leave many of them, as rural practitioners know only too well, far below the proper standard. Some receipts in respect of the French debt make a welcome, though somewhat belated, appearance in the anticipated revenue of 1926-27; the £4,000,000 on which Mr. Churchill relies is, however, not enough to make any real impression on the burden of the British taxpayer, and the payments of £12,500,000 will not begin until 1930.

Of considerable interest to the medical practitioner is the announcement that the Government proposes to abolish the three years' average system of income-tax assessment after the current financial year, and to substitute for 1927-28 the basis of the preceding year's profits. The change will be in accordance with the expressed views of many classes of taxpayers—particularly, perhaps, those whose incomes fluctuate within wide limits—and with the recommendations of the Royal Commission. If this year proves to be a bad one

for the professions and trade generally the Treasury will, of course, stand to lose over the change—unless, of course, the Government finds itself compelled to reconsider the proposal; but so far as can be seen at the moment the year is likely to prove a suitable pivot for the swing-over to the new arrangement. Whatever may be the result in individual cases, in general it will undoubtedly be found less unpleasant to be faced with a heavier demand for tax than usual when recent earnings have been high than it is—as sometimes happens now—when recent earnings have been low, or in the case of some trades non-existent. Relief is to be given for hard cases occurring during the period of transition, presumably those where an individual, having paid on average assessments during lean years, will lose the benefit of those years in future averages; steps will apparently also be taken to deal with the legal evasion which now occurs in the more speculative businesses, where a firm, having had an abnormally profitable year, goes out of business rather than face the effect on future averages, and restarts in conditions to which no liability to bring in the profits attaches.

We are disposed to think that this Budget will add quite as much to Mr. Churchill's reputation as his previous one did; it strikes the eye less forcibly, but it stands on a firmer basis, it contains fewer references to the benefits it will confer on posterity, but it deals effectively with the more urgent demands of the next few years; it may arouse less enthusiasm in some quarters, but it will give more general satisfaction.

RECENT WORK ON THE ROUS TUMOUR.

In the recent number of the *British Journal of Experimental Pathology* Dr. W. E. Gye and Dr. C. H. Andrewes record some important observations on the so-called "Rous sarcoma" of the fowl. It will be remembered that this is the tumour on which the work of Gye and Barnard is based. It is histologically a typical spindle-celled sarcoma. It differs from most other transplantable animal tumours in the fact that it can be transmitted from one bird to another by a cell-free filtrate of the tumour, while most other neoplasms can only be transmitted by living cells. This difference has been regarded by nearly all pathologists as constituting a fundamental distinction. For it was argued that a neoplasm that can be transmitted by a cell-free filtrate is clearly caused by a filterable agent or agents, and such a tumour has therefore been designated by some as an infective granuloma, by others as an infective sarcoma. It seemed to follow with equal force that a neoplasm that can only be transmitted by living cells was not caused by a filterable agent, and that only such neoplasms were true malignant new growths. It may be added that Rous himself looked upon these filterable fowl tumours which he discovered as true malignant new growths. Gye has added two new facts of fundamental importance to our knowledge of these tumours. He showed first that in the transmission by a cell-free filtrate two factors are involved: one is particulate and a living thing—the virus; the other is non-particulate, and is called by him the "specific factor." Both these factors must be injected together in order to produce a sarcoma. Gye's second observation was that he could substitute for the virus of the Rous tumour a virus obtained from true malignant new growths of the mouse, the rat, and of man, so that this substituted virus together with the specific factor for the Rous tumour again produced a sarcoma in the fowl. This second observation links up the Rous tumour with the true malignant new growths by showing that they have one factor in common. The paper just published adduces new evidence, obtained accidentally,

so to speak, in support of the view that the Rous tumour is a true malignant growth. This tumour, as described by Rous and by subsequent workers also, grows with extreme rapidity, and forms metastases so rapidly that it kills the host within a few weeks. This was also its behaviour in Gye's hands during the first three years of his investigations. Suddenly it changed its clinical character: its growth became slow, metastasis was not rapid, and at the same time it could no longer be transmitted by a cell-free filtrate, but only by living cells. Histologically it remained a spindle-celled sarcoma. It therefore showed now the behaviour of an ordinary malignant new growth. It persisted in this behaviour for six months, and then as rapidly reverted to its original character—rapid growth with extensive metastasis and transmissibility by a cell-free filtrate. The filterability of the Rous sarcoma is therefore a variable and not a fixed unalterable property of the tumour. It varies with the clinical behaviour of the tumour without affecting the essential microscopic structure, filterability being associated with rapid growth and a high degree of malignancy. Such fluctuations in the rate of growth are not a new phenomenon; they were, in fact, recorded by Bashford, Murray, and Cramer twenty years ago as one of the first observations on the behaviour of transplantable mouse tumours on continued propagation. These new observations, by showing that filterability does not constitute a fundamental difference between the Rous fowl sarcoma and other transplantable tumours, furnish additional evidence that the Rous tumours of the fowl are true malignant new growths, and support the contention that it is legitimate to argue from the etiology of these tumours to the etiology of malignant new growths generally.

THE POLISH INSTITUTE OF HYGIENE.

THE new Polish School of Public Health, which forms part of the Institute of Hygiene in Warsaw, was formally opened on April 20th by Count Skrzynski, Prime Minister of Poland, and we are indebted to Dr. Andrew Balfour, director of the London School of Hygiene and Tropical Medicine, who was present, for an account of the ceremony and a description of the buildings. One of the first acts of the newly constituted Polish Government was to bring together towards the end of 1919 some small laboratories in Warsaw, and so to establish a central epidemiological institute. At first it was entirely concerned with urgent matters, such as diagnosis and the production of vaccines and serums, arising out of the epidemics by which the country was then being devastated; since 1922 it has gradually undergone development, and now consists of four autonomous departments: (1) bacteriology and experimental medicine, including parasitology; (2) serums and vaccines (which has a farm of its own); (3) chemistry, pharmacology, and pharmacy; (4) a school of hygiene. This new school, which is under the general direction of Dr. Chodzko, formerly Minister of Health, and a member of the Health Committee of the League of Nations, was opened on April 20th; it consists of five sections—statistics and epidemiology, social hygiene, industrial hygiene, biochemistry and food, and sanitary engineering. The establishment of this school, which has owed much to the Rockefeller Foundation, is not yet complete; ample provision has been made for a museum, not only for teaching purposes, but for housing models and drawings likely to assist the municipal authorities; since 1924 it has given courses to candidates for appointments, both medical and engineering. "I do not think," Dr. Balfour says, "that a better expression of nationality could be found than in the establishment of these institutions." There was a large gathering at the opening ceremony, including representatives from a great many European nationalities,

and also from the United States and Japan. After the Premier had spoken Dr. Wroczyński, General Director of the Public Health Service of Poland, gave an account of the organization of the institution as now nearly completed. It owed its origin, he said, to Dr. L. Rajchman, director-general of the original epidemiological institute, and now Director of the Health Section of the League of Nations. The Institute of Hygiene had developed rapidly, and with its five or six provincial branches was a complete unit, providing the public health service of Poland with the machinery for technical researches which form the basis of measures for administrative action. The School of Public Health represented a logical development, its object being to train officers for the service of the State and municipalities. The law since the beginning of 1925 required that all candidates for public health offices of the first grade should take a special course of one year, including both practical and technical work. In connexion with the school was a series of model sanitary districts for the instruction of candidates. The Polish State had willingly provided the funds necessary for the maintenance of the institute and of its school; it was felt that at this time of grave economic crises in Europe it was necessary to increase the efficiency of the individual to as high a level as possible by safeguarding him from ill health. The speaker concluded by thanking the representatives of foreign Governments, and especially those present from the Rockefeller Foundation, whose generous assistance had to so large a degree made the creation of the school possible. The reply on behalf of the institution was made by Dr. L. Rajchman, to whose energy, enthusiasm, and far-sightedness, Dr. Balfour says, the new school owes its being, for it was he who was able to enlist the sympathy and help of the International Board of Health of the Rockefeller Foundation in the foundation of the school. The new school (Dr. Balfour continues) is a large building, excellently adapted for the various purposes which it is intended to serve. It is a fine solid rectangular block of five stories. In the basement are the electrical installations, a staff dining room, and other offices. On the ground floor is a bacteriological laboratory for students, a library and reading room, and the director's offices. On the first floor is the department of physiology and industrial hygiene and the museum of public health; on the second floor is a lecture room, the department of epidemiology and statistics, and of social hygiene and public health administration; on the third floor is the students' chemical laboratory and the department of biochemistry; on the fourth floor, which is in mansard, are dwelling rooms for the staff. The new school is not yet fully equipped, but a good beginning has been made. As will be noted, it combines both research and teaching, and will before long prove a useful ally to the older Institute of Hygiene, where already much good work has been accomplished in relation especially to typhus fever, epidemic jaundice, cerebro-spinal fever, the paratyphoid fevers, and blood grouping.

SOCIAL INSURANCE.

UNDER the title *Social Insurance*¹ there is published an extremely valuable report of a conference organized by the League of Nations Union in November last. The book, as was the conference, is divided into seven sections. They deal with the newly established scheme for contributory, widows', orphans', and old age pensions; the unification of schemes of insurance, especially as to administration; national health insurance; workmen's compensation; unemployment insurance; international aspects of social insurance; and family endowment. An appendix contains a bibliography of publications of the International Labour

¹ *Social Insurance*. London: Faber and Gwyer, Ltd. 1926. (Roy. 8vo, pp. x + 228, 5s. net.)

Office relating to social insurance. The whole volume is interesting and its publication opportune. Much of the information it contains—for example, that contained in the address of Mr. H. B. Butler (deputy director of the International Labour Office) on the international aspects of social insurance—cannot easily be obtained elsewhere. Most of the report is, of course, argumentative and controversial, but the discussions are temperate, reasonable, and informative. This is eminently so in the section dealing with the very difficult subject of family endowment—a subject which, though no practical national scheme will probably emerge for a considerable time, is bound to call for increasing attention during the next few years, and in connexion with which the points for consideration should clearly be in the minds of social workers, parliamentarians, and economists. They are well brought out here, and are of distinct importance in connexion with medical and public health problems. In other sections, particularly the first two of those enumerated above, it is interesting to note how the prejudice of a general political theory or of a vested interest can prevent certain minds from considering a subject on its merits. Any insurance scheme on a contributory basis (without which, of course, it would not properly be an insurance scheme at all) has no virtues for Miss Wilkinson; and Sir Thomas Neill can see no value in unification of health administration as it might interfere with the privileged position of approved societies, thereby giving Mr. Kershaw (National Association of Trade Union Approved Societies) the opportunity of asking him “to approach this question from the point of view of what was best for the people, and not from that of the best means of preserving any existing form of machinery.” In the section on health insurance Mr. Kershaw again, and Mr. Alban Gordon even more fully, present very faithfully and fairly the weaknesses of approved societies, and the case for seriously modifying their position in relation to health and social insurance. These addresses are well worth the attention of all insurance practitioners and of all these who are engaged in administrative work in connexion with either Insurance Committees or public health authorities. This is true also of a very interesting, practical, and effective address by Dr. Harry Roberts on insurance medical practice, and his short reply on national mortality which concludes the discussion in this section. Altogether this volume is a storehouse of information and of opinion on the various aspects of the subject with which it deals.

THE BLOOD CHEMISTRY IN WHOOPING-COUGH.

STUDY of the blood chemistry of whooping-cough has brought to light the existence of certain definite variations, which, if found to be of general occurrence, will have an important therapeutic significance. In the *Journal of the American Medical Association* for April 10th (p. 1116) Drs. J. C. Regan and A. Tolstonhor of Brooklyn describe investigations into the chemical changes of the blood during whooping-cough of different degrees of severity in a series of over 100 patients, aged from 4 months to 12 years, 78 per cent. being more than 3 years of age. Estimations, with the usual precautions, were made of the hydrogen ion concentration, and the blood contents of inorganic phosphorus, calcium, carbon dioxide, urea, uric acid, creatinine, and sugar. It was found that a normal range of the carbon dioxide content of the plasma was associated with a lowering of the hydrogen ion concentration and of the inorganic phosphorus. The authors, therefore, believe that in whooping-cough there occurs an acidosis of an uncompensated type (Type 6, Van Slyke classification) in which there is an increased concentration of free carbon dioxide in the blood. These conditions appear early in the disease, the change in phosphorus existing in the catarrhal

stage, and being well marked during the first few weeks of the paroxysms; parallelism in their course was demonstrable, and was held to signify a close relation. The authors think that the characteristic symptoms of whooping-cough thus receive some measure of explanation. The paroxysms interfere considerably with the ventilation of the lungs, and are probably associated with increased alveolar air tension, the amount of carbon dioxide in the blood being thus increased. The vomiting may be a compensatory process aimed at maintenance of the normal acid base balance by elimination of the very acid gastric contents. The deduction was drawn that the administration of alkaline salts might assist the restoration of this balance, and it was found that in moderate and severe cases treated with various combinations of sodium bicarbonate, calcium carbonate, and magnesium oxide, the inorganic phosphorus rose steadily from the third week, whereas in untreated cases the rise did not commence until the sixth week. Similar results as regards the hydrogen ion concentration followed this treatment, which, if applied early, appeared usually to abort the disease; if the treatment was given in the later stages progress to cure was accelerated. The distress produced by the symptoms was rapidly diminished; vomiting ceased, as a rule, in four or five days, and the whooping in about eight to ten days. The patient's general condition improved also, and there was a gain in weight. The authors suggest that alkalis may have a prophylactic value in whooping-cough. They have not employed the treatment when bronchopneumonic complications were present, but good results were obtained from the use of the mercury vapour lamp. There were no constant alterations of a distinct type in the calcium content of the blood, which showed very little change. The authors doubt, therefore, whether the convulsions in whooping-cough are of a similar origin to those of tetany, which are associated with a lowered calcium content. The use of calcium in treatment appears, therefore, to be unnecessary, but they add that in cases of gastric intolerance lime water may be added to the food with benefit, while in neglected cases of severe pertussis in which starvation has complicated the condition, glucose may be combined advantageously with the alkalis. The authors' general conclusions are that in whooping-cough an uncompensated acidosis occurs, which is intimately connected with the pathogenesis of the paroxysms, and that if the acid base unbalance is corrected the clinical symptoms are quickly ameliorated.

HEALTH AND EDUCATION.

PROFESSOR P. M. LELEAN, who was recently appointed to the chair of public health in the University of Edinburgh, devoted his inaugural address at a meeting on April 20th, over which the Principal, Sir Alfred Ewing, presided, to a discussion of the effect of the education system on the health of children. Professor Lelean began by saying that in taking his bearings for a future course in public health he had turned to the lessons of the great war, which had forced us to take stock of our available man power and to classify men of military age. It was found that out of every nine men of military age in Great Britain on the average three were fit, two were on a definitely infirm plane of health, three could almost be described as physical wrecks, and the remaining man was a chronic invalid with a precarious hold on life. That revelation had been a shock to national complacency, and had resulted in an outburst of remedial energy. This had included maternity and child welfare work, to which already the nation owed much. It was only necessary to watch a stream of workers at the close of a working day, or other crowds of people, to realize the extent to which the nation was still C3. It was not possible to unmake

C3's, but an endeavour could be made to place expectant mothers and growing children under conditions so favourable that the next generation might be A1. It was a bad doctrine for the race that 95 per cent. of available funds should be spent in tinkering with a C3-ridden generation, while only 5 per cent. was expended upon the evolution of a new generation so fit that it would defy disease. When the war broke out it had been firmly believed that no soldier could be trained in less than twelve months, but at the end of the war the men were being sent to the front as useful infantrymen in less than two months, while the German training period fell to one month. It was of the utmost importance for the future of the nation that this lesson, the force of which was already waning, should be revived. Professor Lelean believed that some of the younger children were being pressed beyond their mental powers, while of the older children a large proportion were being very seriously overworked. Children's working hours often mounted up to ten hours a day. The *joie de vivre* was crushed out of them by overwork. The result of what he described as a pernicious system was that towards the end of every term children were pallid, irritable, "temperamental," and obviously played out, and parents watched them with growing anxiety lest they should break down before the holidays came. At the end of their school life they came to the higher educational centres like saturated sponges. It had been said by a recent authority that examinations were ruining the intelligence of the nation for all practical purposes. He thought a "Save the Children League" might do good work nearer home than in the Near East. He suggested that the support of parents might be gained for a three-plank platform: (1) to get 30 per cent. knocked off every examination standard and every secondary education curriculum in the country; (2) to ensure that the amount of homework was adequately supervised; (3) to secure for some physiological expert a seat on every educational committee in the country. The family doctor, social worker, and district nurse needed to be conversant with all factors affecting the maternal, industrial, and communal efficiency of the family—the feeding budget, clothing problem, light and fuel bills, recreation facilities, and mental needs. It was by these workers and means that the initial stages of a great advance could most effectually be hastened.

THE FREQUENCY OF BOTULISM.

Of the two forms of bacterial food poisoning, botulism, the more severe variety, is extremely rare in this country, whereas the milder variety, caused by bacteria of the salmonella group, is relatively frequent. In fact, there has only been one authentic outbreak of botulism in this island—that at Loch Maree in the summer of 1922. The disease is commoner in America and on the Continent, and most of our knowledge of this infection has been gained from the experience of the United States. An article in the *Journal of the American Medical Association* for February 13th gives a summary of fifty-six outbreaks of botulism in the United States concerning which information is now available. Twenty-one of these occurred in 1922, twelve in 1923, eight in 1924, eight in 1925, and the remainder in previous years. A total of 159 cases with 124 deaths, or a case mortality of 78 per cent., has been recorded. The preserved food products concerned, so far as known, were vegetables in thirty-eight outbreaks, meat in four, fish in four, fruit in one, pickles one. In thirty-six outbreaks the food was home canned, and in eleven commercially canned. Home-canned string beans has been much the commonest vegetable responsible for outbreaks of botulism. It will be remembered that in the Loch Maree outbreak very little if any alteration in the appearance or taste of the incriminated food was detected. But this

appears to have been exceptional, for in the majority of outbreaks of botulism the preserved foods responsible have been noted to be visibly spoiled. But this spoilage is not a trustworthy indication, for often containers have been normal in appearance and the disintegration of the contents so slight that no abnormal odour or taste was detected. In the fifty-six outbreaks of botulism previously referred to, information as to spoilage is available in forty-one. Eighteen of the foods implicated were stated to be normal in odour and taste, and there was nothing unusual in the appearance of the container. In the remaining twenty-three the preserved food and its containers appeared abnormal, though it was tasted and served as food. The disease botulism is, of course, produced by the toxin of *Bacillus botulinus*, and two types of this microbe have been differentiated—A and B. The type of toxin present has an important bearing should treatment with antitoxin be instituted. In the outbreaks included in this American series information is available as to type in twenty-four. Of these twenty were Type A and four were Type B.

A PRIMITIVE AUSTRALIAN SKULL.

At a recent meeting of the Victorian Branch of the British Medical Association Dr. W. Colin Mackenzie gave an account of a human skull recently found at Columa, on the Murray River. Dr. Mackenzie is well known to orthopaedic surgeons on account of the contributions he has made to the treatment and re-education of muscles in paralysed children, and has of late years devoted himself to anatomical and allied inquiries. In his address to the Victorian Branch Dr. Mackenzie claimed that the Columa skull was of great antiquity, and was of a very primitive kind. Unfortunately, no facts have come home which will permit anthropologists to form an opinion as to whether or not Dr. Mackenzie's claims are well founded, and until such data are supplied this latest discovery of ancient man must be placed to the "suspense account."

ARCHIVES OF DISEASE IN CHILDHOOD."

The second number of the *Archives of Disease in Childhood*, published by the British Medical Association—that for April, 1926—has appeared. The first and probably the most important paper is a report by Dr. J. W. McNee, of the Medical Unit, University College Hospital, London, and Dr. G. A. Harrison, biochemist to the Hospital for Sick Children, Great Ormond Street, on an investigation of sclerema neonatorum, with special reference to the chemistry of the subcutaneous tissues. As only the first part of the paper, which is long and illustrated by coloured plates, is published, we postpone notice of the conclusions reached, which are likely to be of very considerable interest. The second paper is by Dr. F. C. Shrubbsall, of the Maudsley Hospital, who deals with the special schools of London, including those for the blind and myopic, the deaf, the physically defective, the mentally defective, epileptic children, and open-air schools. The third paper is an account of lambliaias by Dr. Reginald Miller, of the Paddington Green Children's Hospital. Intestinal infections due to the flagellate *Lamblia intestinalis* attracted attention in England in the early years of the war, when the disease first reached this country from the eastern fronts. Dr. Miller's paper is founded on twenty-three cases in children, and his conclusions are that the infection is now by no means rare in hospital practice amongst children; that it produces chronic enteritis; that the resultant diarrhoea causes a child to fall considerably below weight, and occasionally retards development and diminishes growth; and finally, that even in children true "carriers" may be found, infected with lamblia but without symptoms. The next paper is from the Birmingham Children's

Hospital, and in it Dr. J. M. Smellie discusses the remote prognosis of empyema in children. The examination of thirty-six children after operation for empyema leads him to the opinion that the remote prognosis is good. Nephritis in children and its prognosis is the subject of a paper by Drs. Donald Paterson and W. G. Wylie, from the Hospital for Sick Children, Great Ormond Street. The general conclusion seems to be that the prognosis is not very good, but this statement is subject to many qualifications, and the paper itself should be studied. The last paper is by Dr. Alan Moncrieff, now medical registrar of the Middlesex Hospital; it deals with current problems in the tuberculosis of childhood, and is of the nature of a general review.

INFLUENZA.

Last week the number of deaths in the great towns again increased—from 294 to 302—but the increase was small. In London there was a decline—from 74 to 59. Four cities other than London returned 10 or more deaths—Birmingham (21), Liverpool (16), Manchester (14), and Oldham (10). The notifications of pneumonia decreased from 2,074 to 1,876. The indications are that the recrudescence is not far from its maximum, and is of a mild type. It seems very improbable that the total casualties will equal those of 1924.

PUBLIC HEALTH IN POPULOUS COUNTIES.

ONE of the suggestions made by the Ministry of Health in connexion with the proposals for the reform of the Poor Law was that county councils should be given supervisory powers over and responsibility for health administration within the whole of their area. In the evidence which is to be given on behalf of the British Medical Association before the Royal Commission on Local Government objection is taken to this suggestion in the case of counties containing populous urban areas. It is interesting to note that at the annual meeting of the Association of Municipal Corporations held last week this same objection was unanimously endorsed. To have a superior and a minor health authority dealing with health problems within the same area is bound in such circumstances as those indicated to lead to confusion, overlapping, and even disagreements.

THE KING has appointed Sir Harry Baldwin, C.V.O., M.R.C.S., L.D.S., to be Honorary Surgeon-Dentist to His Majesty, and Mr. Guy Capper Birt, M.R.C.S., L.R.C.P., L.D.S., to be Surgeon-Dentist.

THE Linacre Lecture will be delivered at St. John's College, Cambridge, by Sir Frederick Andrewes, M.D., F.R.C.P., F.R.S., professor of pathology at St. Bartholomew's Hospital, on Thursday, May 6th, at 5.15 p.m., in the Lecture Room of Anatomy and Physiology, New Museums. The title of the lecture will be "Disease in the light of evolution."

By an Order of the Committee of the Privy Council, Lieut.-General Sir William B. Leishman, K.C.B., K.C.M.G., F.R.C.P., F.R.S., Director-General Army Medical Services, has been appointed a member of the Medical Research Council, of which he had ceased to be a member in 1922. The vacancy thus filled was consequent upon the recent approval of amendments to the Royal Charter of the Medical Research Council, which provide, *inter alia*, for an increase in the number of members from ten to eleven. Under the amended charter, two of the eight scientific members will retire in each year, and one of the three other members in each second year, the scientific members being not eligible for reappointment before the end of one year after retirement.

Union of South Africa.

[FROM OUR CORRESPONDENT IN JOHANNESBURG.]

MEDICAL EDUCATION FOR NATIVES.

THE Committee of Inquiry on Public Hospitals and Kindred Institutions last year drew attention to the demand for native doctors. It was pointed out that the medical schools at Capetown and Johannesburg did not admit native students; and persons who represent native interests had urged that provision be made elsewhere in the Union for training them. Overseas training of these students was not looked on with favour. Attention was drawn to the fact that there were "hordes of natives in many centres who had little chance of medical treatment," and that such untreated sick became a menace to the rest of the community.

Acting on this report the Minister for Native Affairs has now appointed a committee to "inquire into the training of natives in medicine and public health," and some very interesting information has been laid before it. It consists of four doctors and two laymen, and is representative of the Government Departments of Native Affairs and Public Health, of the Universities of Capetown and Johannesburg, and of the medical profession.

There can be no doubt that the provision of more medical services to the vast native population of this country is urgently necessary. In round figures there are in the Union of South Africa one and a half million Europeans and five million natives, and there are fewer than two thousand medical practitioners on the *Register*. European practitioners find little inducement at present to practise in the kraals, and very few do it for long. The need for additional medical services is felt particularly in the native reserves, where the proportion of medical men to natives is not infrequently in the neighbourhood of one to fifty thousand. Witnesses estimated that to provide reasonably efficient medical services there should be approximately one doctor for every five thousand natives.

Since there is an obvious demand, and since it appears to be impossible to supply it with European doctors, the training of native doctors who would be content to work among their own people is the evident solution. Such practice is never lucrative, but more important deterrent factors for Europeans are the lack of social amenities and unfamiliarity with the language and customs of the people. Locally trained native doctors would better understand the patients; there would be the common bond of race and language; and they can be expected to show considerable enthusiasm about the work of uplifting the people. But the question of training such students raises difficulties which can hardly be appreciated by persons unaware of the conditions obtaining in this country.

Colour prejudice in any country where the blacks very greatly outnumber the whites is apparently unavoidable. It is developed remarkably quickly in Europeans who arrive here as settlers, and with hardly an exception it is present in the psychic make-up of every South African-born European. It is most clearly revealed in the lower, labouring grades of white society, where the danger from native competition is most insistent. But it is not absent from the skilled and intellectual grades. In these circumstances the solution of the problem by the admission of natives to the two medical schools in the country with exactly the same privileges as the European students is generally considered to be out of the question. Promising native students might, with support from the Government, be sent overseas to qualify in medical schools, where they would be admitted on terms of absolute equality with their fellow students. This would probably be the most immediately economical way of training them. The danger, however, is that a lengthy stay in a large European town would tend to defribalize such students. The probabilities are that on their return to South Africa such men would not be content to work entirely among their own people in the kraals, for which their training was intended. Principal Kerr of the South African Native College did indeed submit to the Government last year a scheme for

training native medical students overseas. The first, or pre-medical year, would be done at the Native College. The remainder of the course would be done overseas at an annual cost per student of £200. Of this the guardianship would be called upon to provide £50 and the Government £150, of which £50 would be a scholarship and the remaining £100 a loan. The loan of £100 per annum for five years would be repayable with interest when the student commenced practice, in accordance with a scheme already drafted regulating loans to native students. But overseas training is very strongly opposed by many educated natives. It results in the students getting out of touch with their own people; they adopt European habits and methods of living, and they become "infected with ideas unsuited to South Africa." In the long run it will probably be cheaper to train the large and increasing number of native students in this country.

It has been strongly urged that natives should be trained at a medical school of their own, to be established at some large centre such as Durban, in Natal. But this would involve an enormous initial expenditure, and would necessarily divert funds from the two existing medical schools. Some have suggested that a shorter course might be provided at small expense; but it is very unlikely that such a suggestion would be favourably received. The general feeling appears to be that if the native is to be trained at all he should attend the full course, and, on qualification, be admitted to the *Register* with full privileges. Some method might be devised whereby the facilities already available at Johannesburg and Capetown might be utilized for the training of natives. Classes might be conducted in duplicate; or there might be partial segregation in the classes. This would be quite simple in the laboratory and the lecture room, the natives working at a separate bench and sitting in a reserved portion of the theatre. Their clinical instruction could be given entirely in the native wards. Some solution must be found soon; and the report of the committee inquiring into the matter is awaited with interest. Meanwhile there has been raging in the daily press a discussion in which clerical, medical, and university men are taking part as to whether the mentality of the South African native or Bantu is potentially equal to that of the European. As affecting the question of the professional training of natives, it is of interest to note that there are already practising in the Union six Bantu doctors, and their practice is by no means confined to natives.

UNIVERSITY OF THE WITWATERSRAND, JOHANNESBURG.

THE 1926 session commenced on March 11th. Sixty-five new medical students were enrolled. Of these, sixty entered on the first year of study and five entered on the second year, having completed the first year at one of the other universities. Altogether there are this year 230 students spread over the six years of the course. This is an increase of fourteen over the number of medical students at the beginning of 1925. This year there has been provided for the first time a course leading to the Diploma in Public Health. Seven students have commenced on Part I of the course. The new regulations adopted by the British General Medical Council, which came into force in Great Britain on January 1st, 1924, have been adopted almost unchanged by this university.

The fifth annual graduation ceremony of the university was held in the Town Hall, Johannesburg, on March 27th, the Vice-Chancellor (the Hon. J. H. Hofmeyr, Administrator of the Transvaal, and former Principal of the University) conferring the degrees. The degrees of M.B., Ch.B. were conferred on L. D. Adler, B.Sc., M. Adler, B. Bessarabia, Susanna Blake, B.Sc., I. Carpel, W. A. Dodds, C. Duthie, I. Effen, Esther Franks, F. P. Grobbelaar, S. Javett, I. Liknaitzky, M.Sc., A. Lomiansky, A. Miller, J. S. J. van Rensburg, I. Frack, N. Garber.

M.O.H. JOHANNESBURG.

Dr. Charles Porter retired on March 12th from the post of medical officer of health for Johannesburg, which he has occupied since 1902. Actually Dr. Porter ceased to serve as medical officer of health last August, when he went on

long leave, his leave being coterminous with his period of office. He has been succeeded by Dr. A. J. Milne, a medical graduate of Aberdeen, who has for some years been assistant medical officer of health, and since last August acting medical officer of health, for Johannesburg.

Dr. Porter was born at Cork in 1864, and educated there, in Dublin, and at University College, London. He graduated M.D. and B.Ch. (with honours) at the Royal University of Ireland in 1889, and took the D.P.H. at Cambridge in 1890. He was called to the Bar at Gray's Inn in 1898, and was thereafter, till he left England, frequently retained as a witness in local government and parliamentary inquiries, especially in reference to water supply and sewage purification schemes. In 1900 he was appointed county medical officer of health for Shropshire, one of the most desirable posts at that time in the English public health service. In 1901 he was invited by the chief medical officers of the Local Government Board and of the London County Council, who were entrusted by Lord Milner with power of nomination, to apply for the post of M.O.H. Johannesburg. He at first declined to do so, but eventually accepted the position on certain conditions, including a similar fixity of tenure to that attaching to his post in England. For his temerity in insisting upon the same terms in South Africa as those he had enjoyed in England Dr. Porter was for many years subjected to continual personal baiting in Johannesburg. However, his action in this matter laid the foundation for the fixity of tenure which all health officers in the Union now enjoy under the Public Health Act.

His earliest work (during the last few months of the Anglo-Boer war) included the drafting of the code of public health regulations; the condemnation of the very dangerous old Indian Location and of the Burglarsdorp insanitary area, at a cost of £1,300,000; and the introduction of a much needed system of surface and underground mining hygiene and sanitation such as had not then been attempted elsewhere. Since then the public health organization and progress of Johannesburg has steadily progressed till, as regards its white inhabitants, it stands in the first rank of the healthy cities of the world, with a general death rate of 10 per 1,000, representing a decrease of 31 per cent. in the last twenty years. During the same period recurrences of enteric fever have decreased by 87 per cent., and deaths from that disease by 82 per cent. A material share in this very notable achievement may reasonably be attributed to Dr. Porter's advice and enlightened administration (often in the face of acute hostility), especially in safeguarding water and milk supplies and controlling disease carriers. He has been consulting adviser to the Rand Water Board since its inception, and a member of the Public Health Council of the Union of South Africa for the past six years. A year ago he received from the University of the Witwatersrand, in which he holds the position of senior lecturer and head of the department of public health, the honorary degree of LL.D., in recognition of his services to the university and to the city. He has been president of the Transvaal Town Planning Association, and has sat on numerous Government commissions. He is at present concluding a tour of Southern Asia, and is due to return to Johannesburg shortly to resume his duties at the university.

England and Wales.

THE SPÄHLINGER TREATMENT IN WALES.

A MEETING of the council of the King Edward VII Welsh National Memorial Association was held in Llandrindod on April 23rd, with the president, Mr. David Davies, M.P., in the chair. The medical committee reported that it had held a special meeting to consider the question of the Spählinger treatment, and that at that meeting Dr. Roeyn Jones moved that as a *prima-facie* case for a complete clinical investigation of the Spählinger remedies under competent and unprejudiced medical supervision had been made out, those remedies should be given a trial under these conditions in one or other of the institutions of the Memorial Association in Wales as soon as the remedies were available. This motion was seconded by Professor

E. L. Collis, but an amendment was moved by Dr. J. W. Miller, and seconded by Dr. Ralph Picken, to the effect that as M. Spählinger had promised supplies of his remedy to the Ministry of Health for investigation and the Ministry had promised to make a full investigation, it would be well for the association to await the promised inquiry. The amendment was carried by 15 votes to 1. Another motion, that pending the Ministry's tests, the medical committee should carry out the fullest inquiry possible, was adopted, and the offer of the president to defray the expenses of a visit of selected members of the medical staff to Geneva was gratefully accepted. During the discussion in the council Dr. Roeyn Jones expressed the opinion that as the Ministry of Health had, through unofficial channels, intimated to M. Spählinger in 1922 that he would not be required to divulge the technique by which his vaccines and serums were prepared in the event of a trial of his remedies by the Ministry, the clinical investigations should proceed, and that, if asked, the association should take part in these investigations. He moved an amendment to the effect that in the event of the association being invited it should accept the invitation on the terms and conditions of the Ministry with regard to such an inquiry. The amendment was opposed by Dr. John Jones of Dolgelly; and Dr. Enoch Moss of Wrexham said that the medical committee were simply seekers after truth and facts, and wanted to know exactly where they stood with regard to the whole question. In reply to questions by several members, the president said that the document before the meeting was only an interim report, and the medical committee must have time for full investigation before presenting a final report. The amendment moved by Dr. Roeyn Jones was carried. The principal medical officer (Professor S. L. Cummins) said that this decision affected his position in so far as he was directly responsible for the action of the medical staff, and on the motion of the president the following rider was adopted: "Provided that full information of the nature and strength of the remedies be given in confidence to the medical staff."

CONGRESS OF THE ROYAL INSTITUTE OF PUBLIC HEALTH AT BRISTOL.

The Royal Institute of Public Health will hold its annual congress this year at Bristol from Wednesday, May 19th, until Monday, May 24th, inclusive. The five sections will meet each day at the university, and the following is an outline of the business to be transacted.

Section I—*State Medicine and Municipal Hygiene* (President, Dr. S. Monckton Copeman, F.R.S.).—Papers: "Random recollections of forty years' service," by Dr. D. S. Davies; "The production and distribution of Grade A (tuberculin tested) milk," by Lieut.-Colonel C. Maddock, M.D., and Dr. R. King Brown; "Periodical health examinations," by R. A. Fisher, M.A.; "How to get a smokeless atmosphere—and make it pay," by W. Brownhill Smith; and "Cancer—the need for a wider range of biological research," by Dr. John Brown.

Section II—*Naval, Military, Air, and Tropical Diseases* (President, Surgeon Rear-Admiral Sir Percy Bassett-Smith, K.C.B., F.R.C.S.).—Papers: "The standard of public health of the British Isles, as revealed by the navy personnel of to-day, with suggestions for improvement," by Surgeon Captain R. J. Mackown; "The incidence and prevention of venereal disease in the Royal Navy," by Surgeon Commander Percy F. Alderson; "The relative connexion between chemical warfare, physics, chemistry, meteorology, and public health," by Major H. S. Blackmore; "The interdependence of military hygiene and defence against gas," by Major W. R. Galwey; "Aerial transport of service casualties," (with epidiascope illustrations), by Wing Commander H. A. Treadgold; "Flying in tropical climates, with particular reference to sun glare," by Wing Commander T. S. Rippon; "Cerebrospinal meningitis in the Sudan," by Dr. V. S. Hodson.

Section III—*Industrial Hygiene* (President, Professor Edgar L. Collis).—Papers: Three papers on silicosis by Professor Collis, Dr. Tattersall, and Professor E. H. Kettle respectively; three papers on vocational selection by Dr. Angus MacRae, Dr. W. Salisbury Sharpe, and Mr. J. B. Longmuir respectively; "The ventilation and heating of factories and their influence on health," by Dr. H. M. Vernon. A visit to Messrs. W. D. and H. O. Wills's tobacco factory has been arranged for the benefit of this section.

Section IV—*Pathology, Bacteriology, and Biochemistry* (President, Dr. J. G. Adams, C.B.E., F.R.S., who will open a discussion on cancer).—Papers: "Cerebro-spinal fluid in meningitis," by Dr. Henry Cohen; "The pathology of cardiac infections," by Dr. Geoffrey Hadfield; "Primary pulmonary tuberculosis in children," by Dr. R. G. Cant; "The pathology of endemic goitre," by Dr. G. Scott Williamson.

Section V—*Women and the Public Health* (President, the Duchess of Beaufort).—Papers: "Some defects of reading and..

writing in children, their association with congenital word-blindness and mirror writing," by Dr. Macdonald Critchley. Papers dealing with the care of the crippled child will be read by Sir Henry Gauvain and Drs. R. Owen Morris, A. P. Thomson, and C. W. Saleeby. The advance lines in maternity and child welfare will be included in papers by Lady Barrett, Dr. D. H. Geffen, and Mrs. H. A. L. Fisher. Papers on racial progress will be read by Drs. Innes Pearce, Mabel Brodie, Stella Churchill, Letitia Fairfield, and Mrs. C. S. Hodson. Finally, the health of women workers will be the subject of papers by Miss M. Smith, Miss D. Porteous, Dr. Christine Murrell, and Mr. R. F. Lyne.

A good amusements programme has been arranged for the times not devoted to meetings. There will be a whole-day excursion to Bath and an alternative one to Cheddar, Wells, and Glastonbury. There will also be a visit to the Duke of Beaufort's seat at Badminton, where the party will be shown the grounds and the famous hounds and stables of the Beaufort Hunt. Two evening receptions are being held—one by the Council of the University and the other by the Lord Mayor and Lady Mayoress of Bristol. Any person interested in the work of the congress may become a member on payment of a fee of one guinea. Arrangements for hotel or boarding-house accommodation are being made by the Secretary, the Royal Institute of Public Health, 40, Prince Street, Bristol, from whom a list can be obtained on application.

LEICESTER ROYAL INFIRMARY X-RAY DEPARTMENT.

Largely as the result of a gift of £3,000 by Mr. S. T. Bunning, the x-ray department at the Leicester Royal Infirmary has been reconstructed and equipped with new apparatus of the most modern type. The ceremony of reopening it was performed on April 22nd by the Mayoress of Leicester, and speeches were delivered by Dr. A. E. Barclay, president of the British Institute of Radiology, Mr. W. I. Cumberlidge, F.R.C.S., chairman of the Leicester and Rutland Division of the British Medical Association, and others. The department occupies two floors at the north-east corner of the infirmary, existing buildings having been specially adapted. The standards of protection of the National Physical Laboratory have been secured, and its regulations complied with as regards apparatus. In the dark-room an automatic electrical device has been installed for maintaining the developing tank at a constant temperature, and there is a special table with a moving grid for sweeping up x-ray fog and thus providing better definition in pictures of dense structures. Arrangements for surface and deep electrical treatment, and the production of a continuous current of 200,000 volts, are special features of the improvements which have been effected. Five different types of lamp have been installed for the ultra-violet ray therapy.

CLINICAL PSYCHIATRY AT CARDIFF.

At a large meeting in Cardiff Town Hall, on April 16th, it was decided to form a local branch of the National Council for Mental Disease, to correlate the work of the clinic for incipient mental cases at the Royal Infirmary and other agencies concerned with mental disease. Sir Maurice Craig paid a high tribute to the pioneer work in psychiatry in Cardiff, a sum of over £2,000 being spent annually in research work; he referred to the close co-operation of the Whitechurch Mental Hospital and Cardiff Royal Infirmary. Reciprocity had also been established in the training of nurses by the two institutions. Dr. Edwin Goodall, superintendent of the Whitechurch Mental Hospital, explained how the clinic was the rallying-point for the voluntary treatment of patients in the earliest stage of mental trouble, without stigma of any kind or legal encumbrance. A closer association would now be obtained between those concerned with the education of medical students and persons interested in psychiatry, sociology, criminology, and education. In the evening Sir Maurice Craig addressed a meeting, under the auspices of the Cardiff Teachers' Association, on mental hygiene in relation to child training and education.

A NEW CONVALESCENT HOME FOR THE CARDIFF ROYAL INFIRMARY.

A convalescent home for the benefit of patients from the Cardiff Royal Infirmary has been presented by Sir William E. Nicholls in memory of his uncle, the late Mr. Richard Allen. The house, hitherto known as Ty-to-Maen but now

to be called the William Nicholls Convalescent Home, is situated in a large garden at St. Mellons, about five miles from Cardiff. It will eventually take 60 patients, but only 35 are at present accommodated there. Lady Nicholls, who opened the home formally on April 24th, has further added to the amenities of convalescence by presenting a wireless installation. A large gathering assembled at the opening ceremony, including many members of the staff of the hospital and medical school.

Scotland.

EDINBURGH POST-GRADUATE COURSES IN MEDICINE.

A COMMITTEE of the University and of the school of medicine of the Royal Colleges, which organizes the Edinburgh post-graduate courses in medicine, has just issued a programme of the courses to be held during the summer of 1926. These courses were given annually until the outbreak of war. They were resumed after the cessation of hostilities, and with each succeeding year greater facilities for post-graduate study and instruction have become available. In addition to the specified courses, graduates who desire to study in Edinburgh at times other than that specified in the syllabus, or who wish instruction in other branches of medicine or surgery, can arrange for this by communicating with the secretary of the courses. The courses are open to both men and women graduates, and application for enrolment should be made to the Secretary, Post-Graduate Courses in Medicine, University New Buildings, Edinburgh. The courses specially arranged include a course in obstetrics and gynaecology, a course on diseases of children, a general medical course, and a general surgical course.

The course in obstetrics and gynaecology will commence on July 12th, and last for four weeks, comprising clinical midwifery and clinical gynaecology, obstetrical and gynaecological anatomy, physiology, and pathology, child welfare and ante-natal clinics. It will be held daily at the Maternity Hospital and in the gynaecological wards of the Royal Infirmary. The course on diseases of children will commence on August 2nd and last for one week; it will consist of clinical demonstrations and systematic lectures, and will comprise about twenty meetings; the diagnosis and treatment of the common and important diseases encountered in medical practice will be dealt with, and the dieting of infants and children will be included. The general medical course will begin on August 9th and will run for four weeks. It will assemble daily at 9 a.m. and continue with intervals until 6 p.m. There will be a daily demonstration of applied anatomy, and a series of meetings for the clinical examination of the different systems; the respiratory system, the ductless glands, the renal and alimentary systems, the nervous system, and the circulatory system will be taken up in turn for one week each. There will also be clinical meetings in special hospitals and departments for infectious diseases, dermatology, venereal diseases, diseases of children, diseases of the eye, tropical diseases, and diseases of the blood. The subjects of biochemistry, morbid anatomy, bacteriology, radiology, and tuberculosis will be treated by lecturers on these subjects in a series of demonstrations. The general surgical course runs concurrently with that on general medicine, and certain of the demonstrations will be attended by members of both courses, such as applied anatomy and a series of special lectures on subjects of general medical and surgical interest. The surgical course will include, in addition to clinical meetings on general surgery, the surgical diagnosis and treatment of renal disease, abdominal surgery, and gynaecological operations. There will also be demonstrations on venereal disease, surgical pathology, physiotherapeutic methods of treatment, and surgical physiology. In both the general medical and general surgical courses appropriate medical and surgical clinics will be held in the Royal Infirmary and in the wards of the Royal Hospital for Sick Children.

During the period of the general courses, special courses on vaccine therapy, medical chemistry, and diseases of the blood will be available for those graduates who desire to

engage in special study of these subjects. At other periods than during the special post-graduate term from July to September, courses will be held also on tuberculosis, clinical therapeutics, insulin therapy, venereal diseases, surgical pathology, diseases of the nose, ear, and throat, and ophthalmoscopy. The following post-graduate courses are regularly provided by the University in the ordinary university terms and are suitable for graduates: medical entomology and parasitology, diseases of tropical climates, psychology and experimental psychology, bacteriology, chemical physiology, and methods of clinical investigation.

SCOTLAND'S HOUSING PROBLEM.

A two-days' conference on Scottish housing was opened in the City Chambers, Edinburgh, on April 22nd, under the auspices of the Scottish National Housing and Town Planning Committee. The conference, which was attended by about 200 members representing local authorities throughout Scotland, was opened by Lord Provost Sir William Sleight, who said that the object and purpose of the new Scottish Housing and Town Planning Committee was to enlist the interest and support of local authorities in securing adequate housing provision of good standards throughout the whole of Scotland, and to represent Scottish opinion in relation to Government proposals dealing with housing and town planning. Sir Henry Ballantyne, honorary president of the committee, said that houses were being put up for miners and other sections of the community, but ploughmen's houses in rural areas were in a state as bad as or worse than they were when they were visited by the Royal Commission between 1912 and 1917. The housing condition would never be got into proper order until part of the burden of rates and taxes was removed from houses. The present system was a vicious circle, taxing one section of the community to provide subsidies for a certain class. Mr. W. E. Whyte, in submitting a survey of the housing situation in Scotland, mentioned that tenders for the erection of two- and three-apartment houses had disclosed the fact that three-apartment houses cost only £25 or £30 more than two-apartment houses. On the score of cost, therefore, local authorities should carefully consider whether it was desirable to add to the number of two-apartment houses in their areas. Scotland was oversupplied with small houses, and there was a certain stigma attaching to the statement that every second person in Scotland lived either in a one- or a two-roomed house. There were too many one-roomed houses in Scotland, and nothing should be done to encourage the extension of that type of dwelling.

A discussion ensued on housing in the larger towns, in the course of which Councillor George D. Brown of Edinburgh mentioned that the problem of housing a single person in a house of his or her own had been exercising the minds of authorities. In Edinburgh no one-roomed houses were being erected, but in areas of the slums which were being cleared there were many single persons who desired a one-roomed house, having no need for more than one room and not being able to pay for two. It was suggested that many of these might be persuaded to give up their own homes and go to reside in a hostel. Councillor Morton (Glasgow) expressed regret that the housing problem should have been mixed up with politics. It was difficult, he said, to define what a slum really was, but the word might be taken to mean buildings which had outlived their usefulness, being the relics of a less civilized age, without the sanitary conveniences which were a *sine qua non* of present-day civilization. The Glasgow slums consisted of properties which dated back 100 or 150 years, and had from time to time been extended without regard to either light or air. Various conditions combined to make a dismal, squalid neighbourhood, in which to live was only existence. Reports from caretakers of rehousing schemes showed that 80 per cent. of the tenants made an attempt to live up to their better surroundings, and the medical officer of health reported that the health of the children was improved beyond measure, so that alone fully justified the efforts of the corporation.

A discussion on rural housing, introduced by Lord Polwarth, showed that there must be about 100,000 families regularly employed on the land in Scotland whose houses

required consideration because they fell below modern standards. The problem was complicated by the system of having farm workers living on the farms where they worked, instead of in the villages. It was impossible for local authorities to put up houses for the farm workers unless the workers lived in the villages. Most of the best cottages had been built in the seventies, when agriculture was booming, but the standard of fifty years ago was below the standard of to-day. While it was said that the coal-mining industry barely supported itself, the arable farm of to-day was living on its past, and nothing could be done by the farmers towards putting up buildings unless State assistance was available in the form of a subsidy and a loan at low rates. A resolution was passed by the conference urging upon the Government the necessity for improving the housing of farm servants in Scotland, and for this purpose making an inquiry into the whole situation at the earliest possible date.

BLINDNESS IN GLASGOW.

Since the report by the Departmental Committee on the Causes and Prevention of Blindness, and the coming into effect of the Blind Persons Act, there has been a growing keenness in ascertaining the condition of the blind. A report has now been issued by the Joint Committee of the South-West of Scotland for the administration of the Blind Persons Act dealing with conditions ascertained in Glasgow and its neighbourhood. This report deals with the city group, and covers 1,206 adult blind persons out of a known total of 1,587 persons over 16 years of age. The work has been done under the supervision of Dr. J. L. Halliday, the medical officer in the public health department, who carried out the analysis in collaboration with Dr. Freeland Fergus, who conducted the routine examination of the blind. Mr. William Jones, secretary to the department, gives a statistical review of the data collected. The largest group of blind persons owe their condition to the effect of congenital or acquired venereal disease. These number 17 per cent. (or if doubtful cases of syphilis be included 24.9 per cent.). Of the 17 per cent., syphilis accounted for 12.7 and gonorrhoea 4.8. These figures are compared with those recently published by Bishop Harman for 5,000 London blind persons of all ages; he found blindness in 11.5 per cent. from syphilis and 2.5 from gonorrhoea. The report discusses these affections fully, and points out that the prevention of blindness from these causes is bound up with the prevention and treatment of the original disease. Local authorities have, since 1917, been authorized to provide facilities for treatment, and there is evidence that diminution in the incidence of syphilis is taking place from year to year. Among the measures for the prevention of congenital syphilis facilities for ante-natal treatment take a prominent place. Much depends upon the assiduity with which individual patients attend for treatment; and although some improvement in this respect is taking place there still remain some 50 per cent. whose attendances at the clinics cease prematurely. This is a feature which has received serious consideration, and is one of the arguments in favour of some form of notification. As regards gonorrhoeal ophthalmia, an affection which has been notifiable since 1912, an instructive description and chart is given, showing the sharp increase in the incidence which took place during the war and the very considerable decline which has followed since 1919. Prevention is closely bound up with the adequacy of the arrangements for treating ophthalmia in the newborn, the supervision of midwives, prompt notification, and especially institutional treatment, such as has been established at the Glasgow Baird Street Reception House. Injuries as a cause of blindness were found to be responsible for 16 per cent. of the cases, and inquiry showed the unexpected result that the accidents of civilian life, to which children are specially liable, caused twice as many cases of blinding as did occupational injuries. There is reason to believe that the public are not sufficiently aware of the importance of early and prompt treatment where the eye is involved in injury, especially in children, and there

¹ Report on Blindness in Glasgow, by the Joint Committee for the South-West of Scotland for the Administration of the Blind Persons Act, 1920. Glasgow: Robert Anderson, 1925. Pp. 57.

is held to be room for propaganda along these lines as regards both prevention and treatment. Senile cataract appears third among the causes of blindness. In dealing with the economic status of the blind the report states that of 2,903 blind persons in the south-western counties 177 are of school age; 227 are employed in institutions and 414 are otherwise employed; 198 are returned as untrained but employable; the large residual group of 1,703 (742 males and 961 females) are included under the heading "unemployable," and form about two-thirds of the whole number of blind. Many of these are middle-aged and elderly persons, dependent upon poor relief, charitable agencies, insurance societies, old age pensions, and the like; but there is still too little direct knowledge of the conditions of this class of blind persons. Dr. Freeland Fergus found some cases on the register of the blind who did not, in his judgement, come within the definition of the Act. It is advised that, in future, admission should be controlled by medical examination, and that in cases of doubt a specialist should be consulted. The report is well worth the study of those interested in the blind, whether from the medical standpoint or the administrative; and the authors are to be congratulated upon the clearness with which they state the facts and draw the proper conclusions.

THE DEAF AND DUMB.

The annual report of the Edinburgh Deaf and Dumb Benevolent Society stated that during the year the society had distributed an increased amount of relief to deserving cases. Assistance had been given in the form of rent relief, monetary help, provision of medical attention and medicine, of clothing, and in some cases of dental and optical treatment. Under the society's care there were a number of old men and women without homes and often without friends, because the handicap of deafness tended towards isolation, which was accentuated in old age. The committee of the society was seeking to secure a home where these lonely persons might end their days in comfort under the care of people who could converse with them and interpret their needs. The society found it increasingly difficult to obtain work for young people leaving school. This was unfortunate because the boys and girls had been trained to habits of punctuality, order, and concentration, and many of the older deaf and dumb men and women engaged in large factories had in the past been found to give complete satisfaction to their employers.

EDINBURGH FOOT CLINIC.

The annual report of the Edinburgh Foot Clinic for the past year shows that the number of patients attending was 1,211, who received a total number of 3,994 treatments. At the end of February, 1926, there was a waiting list of 2,029, of whom 423 were new patients. It was stated that the work of the clinic was much hampered by inadequacy of premises, and that a sum of £3,000 was required to complete the purchase of suitable premises and to adapt them for the purposes of the clinic and a school of chiropody. At present no further engagements with patients could be made except for a period of six months in advance.

Ireland.

SALARIES OF DISPENSARY MEDICAL OFFICERS.

A DEPUTATION from co. Mayo, consisting of Dr. A. McBride, Dr. Coughlan, Dr. Conor Maguire, and the Irish Medical Secretary, waited on Mr. S. Burke, Minister for Local Government and Public Health, who was accompanied by Dr. E. F. Stephenson, chief medical officer, and placed before him figures which showed relatively and comparatively with adjoining counties the marked inadequacy of the salaries of the Mayo doctors. The Minister admitted the inadequacy of the salaries, but stated that at the present time he was not prepared to take such a drastic step as to issue a sealed order over the heads of the local authority fixing a scale of salaries. The members of the deputation expressed their disappointment at this decision,

and handed the Minister the following statement for his further consideration with regard to the position of the co. Mayo doctors:

1. That there is no uniformity in the salaries nor any graded scale in force, such as prevails in the county of Galway and other neighbouring counties.

2. That the medical officers have made several appeals without any effects to the county board of health for increases of salary, and a graded scale similar to the scale in force in the adjoining county of Galway.

3. That the medical officers asked the board of health to meet a committee of the medical officers in conference, in the hope that a friendly conversation would lead to a satisfactory settlement, but the board of health refused to meet the doctors, and deferred consideration of the question indefinitely.

4. That the medical officers have appealed to the Minister of Local Government, both by letter and deputations, asking him to exercise his powers in the matter and to fix a graded scale to salaries with pay and promotion on the same scale as the medical officers in the county of Galway have at present.

5. That the Minister of Local Government admitted that the salaries of the Mayo doctors were inadequate and urged the board of health to settle the matter, yet nothing has since been done.

6. That they have been smarting under a gross injustice for years, and they feel that they are entitled to receive a wage at least equal to the doctors in Galway and the other counties in Saorstát Éireann. The Mayo doctors have now reluctantly decided that they must in self-defence withdraw their services as stated above, unless some arrangement is made to give them a graded scale of salary.

Correspondence.

THE SPAHLINGER TREATMENT.

SIR,—I have read the report of the Spahlinger treatment with interest, and I may say that it repays close reading. The bulk of it is an incomplete résumé of what is already known, and it is obviously drawn up with the object of discrediting the whole matter.

It is stated that the only evidence existent "rests upon the observations of some clinical observers who have been favourably impressed by the results which they are obtaining." Might one ask what more is desired on the clinical side?

The strictures upon the secrecy of the laboratory side have been debated *ad nauseam*. I have heard both sides; and on the balance of evidence I think that Spahlinger has some show of reason on his side. But in any case it is a minor question.

The Salford Division has recently undertaken an independent investigation of the present state of affairs. I would call your particular attention to the fact that the Division has examined the position, and has wisely refrained from passing an absolute opinion on the efficacy of the treatment.

It was necessary to examine published records and to consider the professional character of the medical men who were responsible for them. To any honest mind it was obvious that the results of over 400 cases were remarkable, provided one was satisfied that the clinical observers were not all engaged in one huge conspiracy of lying. There was no evidence of such a conspiracy, and the Division then considered the position which arose. It was felt that there was sufficient evidence to warrant an extensive trial in this country, and the supply of the necessary vaccine was then discussed. The financial position of Spahlinger was explained, and it was stated that about £60,000, vested in British trustees, was required to pay off the debts on Spahlinger's estate and to start a branch institute in England. It was further stated that a supply of vaccine sufficient for an extensive test could be produced within twelve months, provided that the institute in Geneva could be put upon its financial legs.

The Salford Corporation has appointed an Executive Committee, composed of members nominated by the corporation and the Panel Committee and some co-opted members from the local Division of the Association, to report upon the treatment and upon the possibility of obtaining a supply of the remedies.

The Division has refrained from comment upon the financial questions involved, but since the matter has been raised by your Science Committee I will take leave to point out some aspects of the question. If Spahlinger publishes

his methods now and is unable to supply the complete range of his antigens, then the person who will obtain the credit, supposing the treatment is a success, will be the man who first prepares them, publishes his results, and makes the antigens available to every practitioner who requires them. That man will be looked upon as the research worker to whom credit is chiefly due. There are other instances of such a happening.

Another point is that Spahlinger may possibly feel that he is at least entitled to his expenses. I hope I am not unduly cynical, but it appears to me that most of the financial gain accruing from a successful discovery is reaped by the clinician, and the research worker who originally published it can rot for all anybody cares.

I note the requirements laid down for the test and for the standing of the men supervising it. If the test should be undertaken in this area I have no doubt that we shall be able to satisfy both requirements without assistance. The Salford Division has some knowledge of the activities of the Ministry of Health, and it is conceivable that past experience has made "dear old Spahlinger" somewhat wary of entering that particular fly-trap.

The attitude of the Division is utterly impartial; it is concerned solely with arranging a test to settle the whole affair, and has expressed itself quite clearly in its resolution passed on March 9th last:

"... that the evidence of the efficacy of the Spahlinger treatment of tuberculosis is such as to justify (1) its recommendation to the public for favourable consideration, and (2) a request for a complete clinical investigation in Britain under medical supervision."

It will be observed that the Division supports an appeal for funds for a test in Britain, and therefore your committee's criticisms upon "money for the dissemination of a 'cure'" are beside the point.

I submit that the Salford Division's attitude is eminently reasonable and that we have done all that can fairly be asked of us. On the ultimate success or failure of the remedy we have no opinion to offer: we merely state that as far as we can ascertain at present there is sufficient bona-fide evidence to warrant the trouble and expense of a lengthy and rigorous test in this country.—I am, etc.,

C. E. JENKINS,

Manchester, April 26th. Honorary Secretary of the Salford Division.

PHYSIOLOGICAL, ORTHOSTATIC, AND NEURO-PATHIC ADOLESCENT ALBUMINURIA.

SIR,—It must have surprised many of my generation to find that a "cure" is now sought for orthostatic adolescent albuminuria, a condition which, thirty years ago, we thought was established as innocent. There can be no doubt that, after severe exercise, it is physiological. "Collier found it present in every one of the Oxford crew of 1906 after rowing a course;" and there can be but little doubt that the ordinary orthostatic albuminuria of the young merely represents an exaggerated tendency of the same kind. As in the case of the sinus arrhythmia of the heart, nervous systemic control has not attained full balance. Neither condition can be "cured." As a rule, both are negligible.

The condition is, in my experience, very common, and in girls not less so than in boys; and the management of the case should, in my opinion, depend upon the general state of health, which may be excellent, though this condition is seldom discovered—because not sought—except in states of ill health, or in the course of a general investigation such as has been sometimes undertaken in boys' schools. To "treat" the condition itself is, I believe, as mischievous as it is to "treat" sinus arrhythmia. The idea of ill health is suggested, parents are alarmed, wholesome exercise is banned, and the prospects of a healthy life are prejudiced at the start.

As to neuropathic (or psychopathic) albuminuria, little, I think, has been recorded, and, though my recollection is that, thirty years ago, it was "recognized," the condition seemed to be regarded as a moot point when raised at a

meeting of the Association of Physicians a few years ago. May I quote a case?

A young married lady, aged 22, the mother of a child a year old, underwent what was, to her, a severe nervous strain. She had, for the first time in her life, to sing in public, at a village concert. Next day she felt "spent," and I was asked to see her. I found the urine loaded with albumin (no casts or blood). There had been no albuminuria during pregnancy; and, though she has had illnesses and operations since then, it has never again been found. She is now, at the age of 60, healthy, active, and full of interest in her travels, her house, her garden, and her grandchildren.

This should tend to confirm the view stated many years ago by Sir James Goodhart, and noted in several editions of Osler's *Medicine*, that, "from a study of the after-history of more than 250 cases, albuminuria of the adolescent has no sinister effect on health or the duration of life."

The question, When does adolescence end? suggests itself. Are young men and women in the twenties "adolescent"? I certainly think that during, at any rate, the first half of this decade, many of them are. The question is that of the early or late development of fully balanced nervous systemic control, and this is probably influenced by many considerations—heredity, individual variation, diet, and environment, among others.

In the article already quoted Drs. Langdon Brown and G. Evans say that: "The condition soon rectifies itself when adolescence is past, and any case of proteinuria" (as it is there called) "in a patient approaching 30 probably does not fall into this category." I have only seen one case of this kind—a man, who had been subject to orthostatic albuminuria in his teens, and in whom I detected the condition, in the course of an insurance examination, at the age of 32. He had been seen by Goodhart when a youth, and had been assured that the condition was of no moment, and that it would disappear. He was much disconcerted, but Sir James, on seeing him again with me, and on referring to his previous notes, reaffirmed the opinion that it was innocent, and relieved the patient's mind. He certainly continued in good health for some years after that, but I have long since lost sight of him. Some people—like Peter Pan—"never grow up," though their lack of maturity may be localized.—I am, etc.,

CLAUDE WILSON, M.D., M.R.C.P.

Tunbridge Wells, April 16th.

THE "SPECIAL REPORT SERIES" OF THE MEDICAL RESEARCH COUNCIL.

SIR,—The first three paragraphs of Professor Blair Bell's letter of April 17th need no comment. I dare say that in time he will be slightly ashamed of the distinction drawn between the "position of the Council-aided, really independent worker" and that of the staff of the National Institute for Medical Research.

In his last paragraph Professor Bell addresses me personally, so, as an individual, I will endeavour to give him satisfaction. On March 6th Professor Bell filled nearly two of your columns with the diets of gentlemen who had experience of, in one case, "a huge number" of chemical plumbers, and added approving comments. The suggestion was that chemical plumbers did not suffer from cancer, while other plumbers did. The only statistical matter provided related to undefined plumbers. Professor Bell noted that the data were dilute, but was "tempted to give them because they accord with the other evidence to be adduced." The argument, statistically speaking, stood thus. A certain subclass of plumbers are immune from cancer, the others not; such advantage as the whole group possesses is due to the subgroup. Professor Bell did not say how many chemical plumbers were included, but there was a hint that huge numbers of chemical plumbers existed. In the census of 1921 "lead burners, chemical plumbers" and "plumbers (not chemical plumbers)" are shown separately. The former numbered 1,021, the latter 49,119. So that even if no other occupational groups (for example, "plumbers' labourers") are included in Professor Bell's statistics, chemical plumbers would form no more than 2.03 per cent. of the combined group, and could therefore make no sensible contribution whatever to the combined experience.

¹ As noted, under the signatures of Drs. Langdon Brown and Geoffrey Evans, in *Price's Medicine* (1922).

It may be noted that if chemical plumbers were treated separately, on the lines of the official assessment of occupational mortality—that is, by taking the experience of three years centred on the census year—we should have approximately 3,000 years of life at risk. Were these subject to the normal rate of mortality from cancer in 1910-12 ("all males") we should expect 3.9 deaths, the expectation being subject to a standard error of at least 1.97. Hence if no deaths at all occurred the divergence from expectation would be well within the ordinary fluctuations of "chance." Professor Bell, who will use for, let us say, illustrative purposes an experience apparently diluted to the extent of 98 per cent., has no use for an experience diluted to the extent of 80 per cent. But if there were really so many as 20 per cent. of potters exposed to lead, and if these did not suffer appreciably from cancer; then, since the mortality from cancer of the whole group is sensibly equal to that of all males, those potters not exposed to lead must have had a mortality rate sensibly above the average.

Professor Bell concluded his exposition of illustrative statistical methods by demanding three things:

"All statistics concerning the matter under discussion must, then, show:

- "(a) Inevitability of lead poisoning.
- "(b) Existence of lead poisoning.
- "(c) The coexistence of one of these conditions with the onset of cancer."

From these I infer that Professor Bell will not be really happy until we can obtain statistics of an industry every employee in which suffers from lead poisoning and some employee in which suffers from both lead poisoning and cancer. I should have thought that if condition (a) were fulfilled, condition (b) must be, but, as it is perfectly certain that we shall never be able to fulfil either condition (a) or condition (c) under existing conditions of life, it does not much matter; I fear Professor Bell will never be really happy.

All the medical statistician can do is to determine whether there is any correlation between index (b), which is available, and mortality from cancer for the existing occupational groups. Dr. Young and Mr. Russell carried out such an investigation and showed that the official data lent no support whatever to Professor Bell's speculations. Professor Bell complains that Dr. Young and Mr. Russell have overlooked the matter of *proper standardization* (I preserve the italics which rejoice the soul of Professor Bell). He claims, indeed, to have indicated how to standardize figures properly. But, as the only figures in his memorandum which were standardized, properly or improperly, had been standardized by the Registrar-General's department, the arithmetically proper, or Bellian, method of standardization remains obscure.

The conclusion I reach is that, upon the point at issue, Dr. Young and Mr. Russell on the one hand, and Professor Blair Bell upon the other, illustrate two different statistical techniques. The former have examined, not some of the available facts, but all of them, have set them out fairly and have drawn no conclusion which the data will not sustain. The latter exhibits the usual defects of the propagandist statistician, the manner of those who, like a deceased politician, use figures as illustrations. Table 2, which, even on Professor Bell's principles, is nonsense, is allowed to stand because it illustrates something.

It is not necessary to inquire very closely whether all the file-makers of Table 3 were really exposed to the risk of lead because they so well illustrate the increase of cancer with the decrease of plumbism. Potters, however, showing an increase of both cancer and plumbism, are suspect; there the risk is not equally distributed. The method is familiar to all politicians.

I sympathize with the investigator who says frankly that available statistics can neither prove nor disprove his hypothesis and absolutely refuses to have anything to do with them. I have no sympathy with the man who would make the best of both worlds, who uses slovenly statistical reasoning to support his case, and abuses those who, reasoning accurately and taking account of the whole of the available data, state that the case is not proved, nor even plausible.—I am, etc.,

Loughton, April 24th.

MAJOR GREENWOOD.

ACCIDENTAL HAEMORRHAGE AND PLACENTAL INFARCTION.

SIR.—In the BRITISH MEDICAL JOURNAL of April 17th (p. 683) a brilliant piece of research work on the above affections is recorded by Dr. Francis J. Browne. Towards the end of his article he points out several important investigations which are required in the elucidation of his thesis: (a) Special tests for the diagnosis of nephritis in the absence of albuminuria. (b) The same for determination of disturbed liver function. (c) The ascertaining of the source and nature of the toxins whether chemical or bacterial (the italics are mine), and "to trace the connexion which undoubtedly exists between accidental haemorrhage and eclampsia. This will involve a carefully co-ordinated and prolonged clinical and experimental study."

In my recent letter in the BRITISH MEDICAL JOURNAL (March 13th, p. 507) entitled "Leucin crystals in urine," a number of points are mentioned, from the clinician's point of view, bordering and touching on several raised in Dr. Browne's article from the experimental side. In that letter (as also in a more detailed article with diagrams of these bodies—not yet published) I point out that the underlying condition of a varied number of illnesses was an intestinal toxæmia with disturbed hepatic function. The general urinary findings were: indican, oxalates, *B. coli*, bile, and bodies resembling impure leucin crystals; the various elements were not all present in every case. I mentioned how these were present in cases of haemorrhage—namely, epistaxis, gastrostaxis, cerebral haemorrhage, menorrhagia. Since then I have found the same condition in two cases of idiopathic retinal haemorrhage in apparently young healthy adults.

Dr. C. O. Hawthorne postulates in these idiopathic haemorrhages an initial thrombosis, mostly following trauma. Dr. Browne says that trauma occurred in some of his cases, but he regards it as coincidental. There was no history of trauma in the two cases of retinal haemorrhage of mine, but the blood pressure was raised. In my article I point out the evidences of increased intestinal bacterial activity with defective liver function; and also the fact of raised blood pressures without any evidence of renal involvement, as judged by the absence of albumin and casts. That the latter is unnecessary for the diagnosis of nephritis is shown conclusively by Dr. Browne in his experiments. I mentioned two types of raised blood pressure:

(a) A case set at a high level, which got periodic exacerbations, at which time the urinary findings were as above. After watching this case for several years there were only two occasions on which albumin was present in the urine.

(b) A case of a young boy of 13 with a systolic blood pressure of 140, and whose urine showed acid ++, bile +, oxalates +++, indican ++, and leucin, but never any albumin or casts. Some four years ago, however, there was what seemed to be a post-scarlatinal nephritis.

Dr. Browne has been fortunate in having used the oxalate method of producing experimental nephritis. It is probably as near to what is likely to occur in nature as could be, as is also the use of coliform organisms. I think it is Sir William Willcox who says that oxaluria is an expression of intestinal toxæmia. Recent writers from Egypt describe a form of nephritis due to *B. coli* which responds to a *B. coli* vaccine administered by the mouth.

The detoxicating influence of the liver is probably in abeyance, and it seems certain that imperfectly metabolized products which act as toxins enter the circulation. Saville talks of uræmia of hepatic origin. This is probably akin to Dr. Browne's nephritis cases with raised blood urea, but no albuminuria.

In Dr. Browne's series of cases there is the record of changes in the liver of only one of the rabbits—namely, round-celled infiltration of the portal tracts in rabbit (September, 1923) after an injection of *B. pyocyaneus*. It would be interesting to know whether these injections of oxalate or coliform germs alters the structure of the liver as well as the kidney, or whether it is only the chemistry of the liver which is disturbed.

One feature which I have found clinically in a large number of cases is the disturbance of the hydrogen-ion concentration of the blood towards an acidæmia; often

no amount of alkali will turn an excessively acid urine alkaline.

In children suffering from acidosis and acetonæmia, which Mellanby believes is due to intestinal auto-intoxication, the acetonæmia is said to arise from the liver. Clinically I have suspected the liver as the source of the lysin which produces the hæmorrhages in these cases.—I am, etc.,

Darlington, April 20th.

R. CHALMERS, M.D., F.R.C.S.ED.

DR. YOUNG'S CANCER PARASITE.

SIR,—At a time when Dr. James Young had the grievance that the pathologists who had condemned his "cancer parasite" would not give it an actual trial, I undertook to provide this on as large a scale as he desired. For the trouble we took and the expense to which our laboratory was put in so doing we have heard no profound expression of gratitude from Dr. Young. It was agreed that he be given an opportunity of producing cancer—not anything else, but just straightforward cancer, for the common lymphoid hyperplasia of mice, to which he has been devoting the full strength of his rhetoric, is no more to be regarded as a malignant tumour than are enlarged tonsils in the human subject. He failed in his attempt: not a single cancer, nor anything in the remotest degree suspicious of a cancer, developed in the animals into which his "parasite" had been injected. That was the conclusive verdict of the trial as far as we, or the committee that asked us to undertake it, were concerned; and I imagine most people will accept it. It was hardly to be expected that Dr. Young would take the adverse result as a sportsman should. The referee, who tried to do his best, was unfitted for the job, says he in effect, because he was prejudiced, narrow-minded, ignorant, inexperienced, incredibly careless, stupid, and untruthful. To bolster up this wholesale condemnation Dr. Young does not refrain from grossly inaccurate statements.

Like many of my fellow countrymen, I love an argument or a fight, but there are certain rules in the game which Dr. Young would do well to learn. I am not, as he suggests, sheltering myself behind the opinions of distinguished pathologists who had previously decided against him, nor am I taking refuge behind the two members of the Pathological Section who later complained that his communication was an insult to the intelligence of the society. I merely agree with them.—I am, etc.,

London, S.W.3, April 24th.

ARCHIBALD LEITCH.

* * We cannot continue this correspondence, which began with a letter from Dr. Young published in our columns on April 10th (p. 675), but are prepared to receive any brief correction which may seem necessary of any matter of fact.

THE KASTLE-MEYER TEST FOR BLOOD.

SIR,—From Dr. Kerr's letter (April 17th, p. 721) it would appear that he has failed to appreciate some of the subject-matter contained in my recent article based on personal research. No mention was made by me of the point whether a positive result would be given with faeces of a patient on a red meat diet, as it was shown that the test was so delicate as to render this conclusion obvious. In medico-legal laboratory work one does not, as a rule, deal with patients on a red meat diet or with those suffering from melaena, although it must not be forgotten that faecal stains may contain traces of blood on this account. In such cases, however, it will be found that a maximum amount of faecal matter is present and only a minimum amount of blood. Again, piles not infrequently produce blood stains upon garments.

Dr. Kerr, I fear, is forgetting that in medico-legal work all the circumstances attending each specific case must be considered carefully before a definite opinion can be arrived at. I disagree with his statement that "it is this extreme delicacy that prevents its use as a medico-legal proof of blood." Before an examiner should arrive at the definite opinion that a stain is composed of blood, not one, but several, tests should be applied, as was pointed out by me in the concluding paragraph of my recent article. The Kastle-Meyer test, as I prefer to call it, was found

by personal experience to be infinitely superior to Day's test, for reasons previously submitted, and as a corroborative test it can be accepted in a court of law with more reliance than the latter test, which possesses very many fallacies, but has been accepted by courts for many years as a corroborative test. I note that Dr. Kerr writes, not from personal experience, but from matter gleaned from but a few sources. Having regard to the many hundreds of tests made by me, using the Kastle-Meyer reagent as a corroborative test, I should not care to associate myself with the sweeping assertion, "It cannot be accepted as a test for blood in a court of law"; but would agree with the statement were it to read, "It should not be accepted as a test for blood in a court of law unless corroborated by other tests," which corroboration is regarded by jurists as the present-day rule.—I am, etc.,

JOHN GLAISTER, JUN., M.D.

Forensic Medicine Department, University
of Glasgow, April 18th.

SIR,—The Kastle-Meyer test for blood, better known as the "phenolphthalein test" of Boas, is certainly one of great delicacy, as I have obtained a strong reaction with a blood dilution of over 1 in 1,000,000.

There is a great difference of opinion as regards the delicacy of this test. Langdon Brown, for instance, states in his *Physiological Principles in Treatment* that he believes it to be less delicate than the benzidine test but more reliable; while, according to Ruttan and Hardisty, it is the most delicate of all the tests for blood, being sensitive to the extent of showing the presence of blood in a dilution of 1 in 10,000,000.

I agree with Dr. Kerr when he states that a positive reaction may be obtained with the benzidine and phenolphthalein tests when applied to healthy faeces. In my experience, positive reactions are not nearly so likely to be got, in such cases, with the benzidine as with the phenolphthalein test. In carrying out the phenolphthalein test it has been recommended that the distilled water used should be prepared in an all-glass apparatus, as the slightest trace of copper in the distilled water may cause a positive reaction in the absence of blood. I have not found this to be necessary. With reference to the reaction got with substances other than blood, I may say I have obtained positive reactions with ferric chloride (10 per cent.) and copper sulphate. Mucus I have found to cause a doubtful reaction on some, but not all, occasions.

I am of opinion that, owing to its extreme delicacy, the results of the phenolphthalein test, for medico-legal purposes or for the examination of stools for "occult" blood, should not be relied on alone but should be used in conjunction with some of the other tests for blood.—I am, etc.,

R. OGILVIE GIRDWOOD, M.B., Ch.B.

Aberdeen, April 20th.

PHTHISIS A DISAPPEARING DISEASE?

SIR,—With Dr. Baskett's main thesis (April 17th, p. 722), of the dependence of phthisis on poverty, and therefore its fluctuation in the opposite direction to the variation in the value of real wages, I am in agreement, qualified by the recognition of other factors of importance. My criticism referred to one of Dr. Baskett's statements (March 6th, p. 449), that "the decline [in phthisis mortality] is not nearly half so fast after 1896 as before it." To warrant this statement Dr. Baskett must express the rate of decline as the average annual decline in the rate, and the point of my objection was that this is a method of estimation liable to lead to erroneous deductions, since a cause of constant potency would, when thus measured, produce a rate of decline steadily diminishing in proportion to the diminution in the quantity on which the cause was acting, and this lessening in the rate of decline might falsely be held to show a slackening in the causes making for improvement. If, on the other hand, the rate of decline is expressed as the average annual *percentage* decline in the rate, then such a uniform cause would be found to produce a constant rate of decline, and, conversely, any change in the rate of decline could legitimately be held to indicate a corresponding change in the causes influencing the fall.—I am, etc.,

Quisborough, Yorks, April 20th.

C. R. GIBSON.

Obituary.

COLONEL C. A. JOHNSTON, C.B., I.M.S.(RET.).

WE regret to have to announce that Colonel Charles Arthur Johnston, C.B., D.S.O., Madras Medical Service (ret.), died of encephalitis lethargica in a nursing home in London on April 23rd, aged 59. He was the son of the late Mr. John William Johnston, deputy collector of Salem, and received his medical education at Edinburgh, where he graduated M.B. and C.M. in 1888. He subsequently took the D.P.H. of the London Colleges in 1896. He entered the I.M.S. as surgeon in March, 1890, attained the rank of lieutenant-colonel after twenty years' service, and was granted the rank of colonel on his retirement in October, 1920. Most of his service was spent in military employment, during which he saw a great deal of war service: the Manipur campaign on the North-East frontier of India in 1891, medal with clasp; Burma, 1891-92, clasp; North-West frontier, Tirah, 1897-98, medal with clasp; China, 1900, medal. During the recent war he served in East Africa, was mentioned in dispatches in the *London Gazette* of June 30th, 1916, and was granted the D.S.O. on January 1st, 1917, and the C.B. on June 4th, 1917. During this campaign he was severely injured by the blowing up of a train in which he was travelling. He was a noted athlete, having been a Rugby international in his younger days, and later in India a good shot, and a polo and tennis player. In 1912 he married Isabel, daughter of the late Dr. J. H. Honeyman of Auckland, New Zealand, and of Lady Bruce-Porter, and leaves a widow and one son.

Dr. T. M. KIMPSTER of Gateshead-on-Tyne died on March 27th. He was a native of Gateshead, and received his medical education at the University of Durham, where he graduated M.B., B.S. in 1888. After holding house appointments at the Newcastle Royal Victoria Infirmary he commenced practice in Gateshead. For thirty-one years he had been honorary surgeon to the Gateshead Children's Hospital, and in 1924 was presented by Princess Marie Louise with a silver salver in appreciation of his devoted labours to that institution. He was honorary medical officer to the Gateshead Dispensary and public vaccinator for the East District of Gateshead. Dr. Kimpster, who had been a magistrate for the borough since 1920, was widely esteemed by a large circle of friends. He was a member of the Gateshead Division of the British Medical Association. He is survived by his widow and four daughters.

Dr. PETER MACLUSKIE, who has died at the early age of 33, was a native of Paisley, and received his medical education in Glasgow. His student work was interrupted by the outbreak of war, and he obtained a commission in the North Staffordshire Regiment in 1914. He resumed his medical study in 1918, and graduated M.B., Ch.B. Glasg. in 1920, obtaining the D.P.M. two years later. After holding the appointment of house-surgeon to the Royal Infirmary of Glasgow he practised in Liverpool for a short time, and then obtained the appointment of assistant medical officer in the mental hospital service of the London County Council, which he held until his death. Both in the army and in his medical practice he won great popularity for his devotion to duty and his loyalty to friends and patients. He married in 1923, and leaves a widow and a young son, with whom much sympathy is felt.

By the death of Dr. H. WICKLIFFE FISHER, at the age of 60, Liverpool has been bereft of one of its well known practitioners. He passed away after a few days' illness, to the grief of many friends, patients, and medical men alike, among whom he was held deservedly in the highest esteem. Dr. Fisher was a member of an old Wesleyan family, received his general education at the Wesleyan College, Sheffield, and studied medicine at the University College of Liverpool. He took the triple diploma of Edinburgh and Glasgow in 1889, and settled down in general practice in the district of Sefton Park. Dr. Fisher speedily evinced those qualities which make for

success. Unremitting in attention, prompt to answer calls, painstaking, sympathetic, especially with children, and temperamentally cheerful, he endeared himself to those with whom he came into contact. Some years ago Dr. Fisher was afflicted with deafness, and at the time he seriously considered whether he would not be obliged to retire from medical practice and take up dentistry. But his indomitable perseverance and cheerfulness came to his aid and he remained in practice, much to the satisfaction of his patients. Dr. Fisher was remarkable in the way he gathered friends around him. He took a keen interest in sports, and was for many years an active member of the Sefton Cricket Club. His funeral was attended by a large number of friends and medical men, a striking witness to the esteem and affection in which he was held. Dr. Fisher leaves a widow and three daughters, to whom we desire to express our sincere regret in the irreparable loss they have sustained.

We regret to announce the sudden death of Mr. THOMAS WATSON HANCOCK, which took place while he was on holiday at Torquay on April 3rd. He was the only son of Mr. and Mrs. John Hallett Hancock of Bracondale, Norwich. He was educated at Bracondale School and at the London Hospital Medical College. He took the diplomas of the London Conjoint Board in 1914 and that of F.R.C.S.Ed. in 1920. After serving for a short time as assistant house-surgeon to the Norfolk and Norwich Hospital he proceeded on active service to France, where he served during the whole of the war, becoming surgical specialist to the 47th Casualty Clearing Station, B.E.F.; for his services he was awarded the O.B.E. At the end of the war he returned to Norwich and became partner to Dr. Basil Nutman. He was senior surgeon to the Jenny Lind Hospital for Children, Norwich, where he inaugurated an ear, nose, and throat department, and was also medical officer to the Norwich municipal ante-natal clinic. Dr. Hancock was a member of the Norwich Division of the British Medical Association. He is survived by his widow and three young children.

We regret to intimate the death, on April 25th, of Dr. MATTHEW FERGUSON ANDERSON of Dundee, from pneumonia, while on holiday at Pittlochry. Dr. Anderson was born at Avonbridge, Stirlingshire, and after being a chemist transferred to medicine, and graduated at Aberdeen in 1885. The subsequent forty years he spent in general practice in Dundee with much acceptance to his patients and to his colleagues. He was a loyal supporter of the British Medical Association and had served the Dundee Branch as a member of its council.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE Budget was introduced on April 26th, and discussion on it continued till the evening of April 28th, when debate arose on a motion regarding the lack of facilities for recreation in urban industrial areas. The Midwives and Maternity Homes Bill, which was reported from a Grand Committee during the week, received a third reading with unusual promptness, and its passage into law seems secure. During the week there have been constant negotiations at the House of Commons concerning the threatened stoppage of the coal-mining industry.

The Parliamentary Medical Committee met on April 21st, and in the course of a general discussion decided that there was no need at present for the suggested deputation of ophthalmologists to the committee with regard to the registration of opticians. The committee considered the possibility of the suggested alterations in the Charter of the Royal College of Surgeons of England being raised in Parliament, and Dr. Fremantle agreed to investigate whether this could be done. It would, it was thought, be desirable that a discussion on medical research should be initiated on the floor of the House, and the members of the committee are ascertaining whether this and other medical subjects can best be raised during debates on the Estimates for Health or Education or on a vote for the Privy Council. The Medical Committee decided that at its next meeting it would, at Sir Walter Fletcher's invitation, visit the Medical Research Institute at Mount Vernon, Hampstead.

MEDICAL NOTES IN PARLIAMENT.

The Budget.

The Budget, which Mr. Churchill introduced on April 26th, provides for the raising of a revenue of £820,750,000 in 1926-27, with a prospective surplus of £4,109,000 after increasing the Sinking Fund to £60,000,000. Apart from remission of the excise duty on tobacco there is no reduction in taxation. The income tax is unchanged, but the Chancellor of the Exchequer gave notice that in twelve months' time the three years' average would be abolished, and that all assessments under Schedule D would be made on the profits of the period of transition, and the right to carry forward losses for six years would be granted. The key industries to hard cases in the period of transition, and the hope of collecting duties are to be renewed for ten years, that on optical glass being raised to 50 per cent., and other small additions being made to the duties. The Chancellor has not abandoned the hope of collecting the bulk of the motor duties and passenger vehicles are fixed for this year the motor duties continue on the existing basis. The duties for commercial goods and passenger vehicles are fixed at a new and generally higher scale. The Exchequer takes for general purposes one-third of the duties unchanged. A Customs and motor cycles, but these duties remain unchanged. The Budget also duty is imposed on imported commercial vehicles. The Budget also contains proposals for the taxation of imported wrapping paper, and for a tax from November 1st on course and credit betting. Tea, sugar, wine, spirits, beer, and patent medicine duties remain unchanged.

In his introductory remarks Mr. Churchill said the attempt to help the coal industry to put its affairs on an economic basis had overshadowed all other interests and claims. The consuming power of the people was increasing faster than the population, but not remarkably so. The consumption of beer had slightly increased during 1925-26 over the previous year, but that of spirits had again fallen, and he must budget for a further fall in the year now beginning. This was due in part to high taxation, but in part to changing national habits. The consumption of tea, cocoa, and sugar was expanding, and the population consumed last year for the first time a larger quantity of sugar per head than before the war. Tobacco held its own, and it would seem that the immense sums expended by the National Exchequer on social services for the mass of the people tended to average the effect of good and bad times.

The Spahlinger Treatment.

On April 27th Mr. Briant asked the Minister of Health if any steps were being taken to make further investigation, if this was necessary, into the results obtained in the cure of phthisis by the Spahlinger treatment; and, in view of the importance of the question to the health of the community, if Government assistance would be given in order to make it available to the large number of persons suffering from this disease.

Sir Kingsley Wood replied that the Minister of Health had offered to send competent medical inspectors to study M. Spahlinger's work at Geneva and to facilitate scientific investigation in this country if M. Spahlinger would supply his materials and method of use, but up to the present neither invitation had been accepted. The second part of the question did not, therefore, arise.

Dr. A. V. Davies asked if it was not the fact that M. Spahlinger had not got the money. Sir K. Wood replied that that might be so. Directly the Ministry received the necessary information and materials they would be glad to go into the matter. Mr. T. Jones inquired if the Ministry of Health did not possess a certain amount of discretionary power to give financial assistance in such a case. Was the hon. gentleman not already a success? Sir K. Wood: No. I think the right course has been taken in that a large number of trade unions have been taken into substantially in order to try to send officers to Geneva to study this matter—namely, to offer to send officers to Geneva to investigate these cases; or to ask, on the other hand, that this gentleman should send the material here, when we shall be glad to investigate it. Mr. Clynes asked if these offers of investigation had been made quite recently. Sir K. Wood replied in the affirmative. They had been made repeatedly during the last three years.

Insurance.

Answering Mr. H. Williams, Mr. Chamberlain said the number of persons insured under the National Health Insurance Act in Great Britain on March 31st, 1926, was about 15,750,000, including persons still within the "free year" of insurance and married women still entitled to special benefits. The number of persons over 70 who were employed so far as medical benefit was concerned, at 290,000, all still insured so far as medical benefit was concerned. On April 26th Sir Kingsley Wood, in reply to Colonel Woodcock, said that no regional medical officers were employed in 1918. The present number and salaries of officers on this staff were: four divisional officers at £1,400; sixteen regional medical officers at £1,000, increasing by £50 to £1,400; thirteen deputy regional medical officers at £800, increasing by £30 to £1,100. These salaries were all inclusive of officers who entered the service at 50 or above (twenty-one in number). The duties were concerned chiefly with the insurance medical service, and national health insurance funds bore the appropriate share of their emoluments. The officers acted as medical referees regarding the incapacity of insured persons for work, and as consultants, they were required to carry out certain inspections under the Dangerous Drugs Act, 1920, and the Blind Persons Act, 1920, and, as needed, to inspect Poor Law institutions.

Hospitals and the Economy Bill.

In moving the third reading of the Economy Bill, Sir Kingsley Wood said there had been misapprehension of the bill's effect on hospitals; he had received letters from various hospitals, alleging that the passing of the clause withdrawing a portion of the subsidy from approved societies would mean a big slice off the income of the hospitals. Anyone who put forward that statement was under a wrong impression. When the first valuation of approved societies was made in 1921 the societies were able to set aside over £300,000 a year for the treatment of members in hospitals and convalescent homes. Of that sum upwards of £200,000 was available for hospitals, so far as the Ministry could expended. On the second valuation, £500,000 and £600,000 a year would be between approved societies liked—and the judge, therefore if the approved societies liked—and the Ministry would not interfere—in the next few years they could give two and a half times as much as they did before. Mr. Lloyd George said 15,000,000 men and women had been promised a few extra shillings a week in time of sickness and a Royal Commission had recommended that 8s. should be given with a special medical benefit in cases of very painful illness. The people had been deprived of that by the Economy Bill. Mr. Blundell said that since the bill was discussed in Committee the fears of the consequences it would have on national health insurance had been diminished because it had become known that in the third valuation period £20,000,000 of surplus had already accrued. The bill was read a third time by 328 to 133.

Midwives and Maternity Homes.

The Standing Committee of the House of Commons resumed consideration of the Midwives and Maternity Homes Bill on April 22nd, and negatived by 25 votes to 8 an amendment (see April 24th, p. 765), moved at the previous sitting, to give the councils of non-county boroughs and of urban districts powers to register and inspect maternity homes. Mr. Trevelyan Thomson contended that the bill would establish in one area two sets of authorities and two medical officers controlling maternity homes. Mr. Peto declared that the local medical officer was far more likely to find out malpractices in back streets. Dr. Fremantle said the promoters of the bill wanted to get at the bad midwife—there were not many of them now—or at the thoughtless, perhaps kind-hearted midwife, who took into her spare room a single girl to see her through her trouble. Eventually such a midwife got two or three women into her home, and that was the sort of home where a shocking loss of life occurred. In a case reported from the South of England "a practising midwife lives in a small house, three bedrooms upstairs, two sitting rooms and kitchen downstairs. She took in three maternity cases, and in addition to these there were three adults and two children in the house. One child had a septic condition of the face. Here there existed overcrowding and a septic focus—result two cases of puerperal infection. The registration and inspection of maternity homes must apply to cases of this kind." The inspector of such a home. Unless the Midwives Act were altered the local medical officer would not have authority to go and see unless puerperal fever broke out or a death occurred. Dr. Fremantle cited other cases from the North of England. Sir Kingsley Wood said it would be a great waste of time and money to make the minor authorities responsible, as they had not facilities for doing maternity work as efficiently as the larger authorities. There were 312 maternity and child welfare authorities which were neither county nor county borough councils. Only twenty-nine had provided their own maternity homes, and only fifty-two made use of maternity homes situated in their own districts. He thought the bill struck a balance very fairly. Mr. Broad said the great improvement in infant mortality since the war was chiefly due to the efforts of the boroughs, not of the counties. If the local medical officer was not the most competent man to do the work, then the county medical officer fifty miles off would be absolutely ineffective. The amendment, as stated above, was rejected.

On the motion of Dr. Fremantle amendments were made giving the applicant or person registered fourteen days' notice of intention to refuse or to cancel registration as a midwife, and giving either side an appeal for quarter sessions. A further amendment was adopted to provide for the keeping of records of a parent who was adopted in a nursing home, save to the custody of a parent of infants or relative. On an amendment enjoining that the notification of a death in a nursing home should be exhibited to statutory certificate of the cause of death, but the amendment was adopted. The provision that the motion of Sir Kingsley Wood in nursing homes was deleted, on the motion of the provisions of the bill "any hospital or institution not carried on for profit from the provisions of Part II of this Act by the local supervising authority." He said it had been represented to the department that there were a large number of small cottage hospitals which had no resident doctor, but were staffed by local doctors who continued to attend their own patients in the hospital. It would be the desire of the Committee that they should be exempted from the local supervising authority were satisfied that they were conducted on the lines indicated. This amendment was for the purpose of meeting the wishes of the medical men in question, who were no doubt doing very useful work. The Committee agreed to the amendment.

On the motion of Dr. Fremantle the Committee added to the bill a new clause giving an officer duly authorized by the super-

visiting authorities power to inspect maternity homes. The Committee also agreed, at Dr. Fremantle's suggestion, that the Central Midwives Board should be authorized to issue a badge to certified midwives. The bill was then reported by the Committee to the House. On April 27th the bill was read a third time without discussion.

Registration of Nursing Homes.

Giving evidence, on April 27th, before the Select Committee of the House of Commons on the registration of nursing homes, Mr. M. D. Thakore, ophthalmic surgeon at Doncaster General Hospital, said he knew homes with charges at five or six guineas a week which were understaffed and where the patients were left alone too long. Patients were chary of making complaints, so doctors and surgeons seldom became aware of these deficiencies. He suggested that as a condition of registration nursing homes should be in quiet streets, and that they should be structurally suitable. There were homes where patients had to be moved from one floor to another after an operation without a lift, and were liable to be jolted when being carried round corners. He himself would not object to registration if, as a medical man, he kept a nursing home. In his view nursing homes should not be allowed to train probationers; every nurse in a home should be trained. Young girls went into these homes in the belief that they would be trained as nurses. After three years such girls were sometimes sent out to private cases. He knew of a case where a child in a nursing home was left in a room by itself, and the staff, to save trouble, took away the hell. Of the six or seven nursing homes he knew, three being in Doncaster, with twelve to twenty-four patients in each, none was thoroughly satisfactory. Answering Dr. Davies, he said he operated in these homes, and had found the operating theatres uniformly satisfactory. He held that where patients had separate rooms no nurse should have more than three or four to attend. Answering Captain Ernest Evans, witness said he knew of no instance where a doctor having a patient in a nursing home was impeded in access to that patient. Replying to Dr. Shiels, he said he knew many instances where patients had been neglected because the staff was overworked.

Evidence was then given by a witness who had been a patient in a nursing home, and the room was then cleared for the taking of evidence in camera, after which the Committee adjourned.

At a previous sitting, on April 22nd, evidence in favour of the registration and inspection of nursing homes was given by Miss K. Scott, matron (Bournemouth); by Miss C. C. Crookenden, owner of a nursing home at Hove; and by Miss F. Potts, chairman of the Birmingham Hostel for Unmarried Mothers.

I.M.S.—On April 19th Earl Winterton, Under Secretary for India, stated, in reply to Colonel Applin, that admission to the Indian Medical Service of members of the Indian Medical Department was one of the matters raised by the recent Anglo-Indian deputation. Colonel Applin's suggestion that the age limit should be extended to 34 years in the case of medical officers who had been prevented from qualifying before reaching 32 by reason of war service would be considered when the views of the Government of India had been ascertained.

Medicated Wines.—On April 19th Mr. Scrymgeour asked the Minister of Health if he was aware that many of the meat and tonic wines, widely advertised as containing no drugs, contained, according to the British Medical Association, from 15 to 20 per cent. of alcohol; and if he would take into consideration the advisability of compulsory notification as to such particulars on the bottles. Sir Kingsley Wood, Parliamentary Secretary to the Ministry of Health, replied that this question was considered by the Select Committee on Patent Medicines, which reported in 1914. The hon. member's suggestion, which was in accordance with the Committee's recommendation, would be considered in connexion with any legislation for the purpose of regulating the sale of secret or patent medicines. Mr. Scrymgeour further asked if Sir K. Wood was aware that a declaration had been made by Mr. W. McAdam Eccles, the eminent surgeon, to the effect that "The public should not be deluded by, but protected from, specious advertisements of these so-called medicated meat or food wines." Sir K. Wood said he was not aware of that statement, but he knew the Committee came to the conclusion summarized in the question. It was a matter which would need legislation.

Hospitals for Coal-Miners.—Answering Mr. T. Williams, Colonel Laurence Fox said that thirty-one allocations had been made from the Miners' Welfare Fund towards the erection or extension of hospitals in Lifford, Newcastle, North Wales, West Yorkshire, South Wales, and West of Dean, and South Wales.

Chief Medical Adviser to the Colonial Office.—On April 26th, Mr. Amery (Secretary for the Colonies), replying to Captain Crookshank, who asked what were the functions of the recently appointed chief medical officer in his department, said that the post to which the hon. gentleman no doubt referred was that of chief medical adviser, whose functions, as the title indicated, would be to advise the Secretary of State generally on all medical and sanitary matters arising in connexion with the Colonies and Protectorates, including measures to ensure continuity of policy and co-ordination of progressive action between different administrations. The post was a new appointment, the creation of which had been authorized in the first instance for a period of three years. In reply to supplementary questions, Mr. Amery said that this was a whole-time appointment, and the salary was £1,500 a year. The appointment was one which the Secretary of State made on his discretion after carefully considering the merits of the different candidates. Dr. Fremantle asked if the officer was

to be in constant touch with the Medical Advisory Committee.

Mr. Amery: Yes; he will certainly be in touch with them.
Maternity and Child Welfare.—Sir K. Wood informed Mr. Briant, on April 27th, that he was not aware that there was uncertainty among county authorities as to the powers of a county authority in connexion with maternity and child welfare when the local sanitary authority was responsible for the administration of the Notification of Births Act. The exercise of powers by local authorities under the Maternity and Child Welfare Act was subject to the sanction of his department, which was consequently in a position to delimit the functions of any authorities with concurrent powers.

Craven Members of the General Medical Council.—In an answer to Viscount Sandon, Major Hennessy said no vacancy had yet arisen on the General Medical Council among the members appointed by the Crown, and therefore there had been no occasion for the Lord President of the Council to come to any decision about the appointment of non-professional persons.

After-Effects of Encephalitis Lethargica.—The Minister of Education states that provision has been made by the Metropolitan Asylums Board for a hundred children suffering from the after-effects of encephalitis lethargica, and that the possibility of making similar provision in the North of England is being explored. Asked whether he was prepared to provide accommodation for adults suffering from the after-effects of this disease in London, Mr. Chamberlain said the best means of providing for such cases was receiving careful consideration from the departments concerned.

Notes in Brief.

Mr. Chamberlain states that the number of sanitary officers who have obtained a special qualification in meat inspection is rapidly increasing.

The Prime Minister hopes to find time this session for passing the Public Health (Smoke Abatement) Bill.

Between September 1st and December 31st last, 7,151 cattle were slaughtered by local authorities under the Tuberculosis Order, 1925.

The Home Secretary cannot fix a date for the introduction of the Factories Bill.

The Treasury authorizes small contributions to hospitals from Government departments in recognition of emergency services to the staffs of the departments.

The number of houses that have been authorized for erection in rural districts in connexion with subsidy schemes under the Housing (Financial Provisions) Act, 1924, is 16,002.

Medico-Legal.

LUNACY CERTIFICATION.

HARNETT v. FISHER.

MR. JUSTICE HORRIDGE, in the King's Bench Division on April 27th, 1926, decided that the action brought by Mr. William Smart Harnett, farmer and fruit grower, of Newington, near Sittingbourne, Kent, against Dr. Henry Holdrich Fisher of Sittingbourne, for damages for alleged negligence in certifying Mr. Harnett insane on November 10th, 1912, and a proper person to be detained under care and treatment, was barred by the Statute of Limitations.

This action against one of the two doctors (the other, Dr. Peufeld, having since died) who signed the original certificate upon which Mr. Harnett was received into a private mental home superintended by Dr. G. H. Adam at West Malling, Kent, was heard before Mr. Justice Horridge and a special jury, and the proceedings, which lasted four days, were reported in the last issue of the *Barrister Medical Journal* at page 762.

The jury found that Dr. Fisher did not exercise reasonable care in certifying Mr. Harnett to be a lunatic at a time when Mr. Harnett was sane, and awarded Mr. Harnett £500 damages.

On the fifth day legal argument was heard on the question whether the plaintiff's right of action was barred because he had not issued his writ within six years of the date on which Dr. Fisher certified him, as required by the Statute of Limitations, 1623 (21 Jac. 1 cap. 16). The material sections are Sections 6 and 7, which read "... all actions for trespass ... and upon the case ... (other than for slander) shall be commenced ... within six years next after the cause of such actions or suit and not after ... provided ... that if any person or persons that is and shall be entitled to any such action of trespass ... actions on the case ... he or shall be at the time of any such cause of action given or accrued fallen or come within the age of 21 years, *non compos mentis* ... then such person or persons shall be at liberty to bring the same actions so as they take the same within such times as are before limited after their coming to or being of full age ... or sane memory at large ... as other persons having no such impediments should have done."

Mr. J. W. J. Gremlyn and Mr. N. L. C. Macaskie (instructed by Mr. H. Coulson) appeared for the plaintiff; and Mr. A. Neilson, K.C., and Mr. T. Carthew (instructed by Messrs. Le Brasseur and Oakley, for the London and Counties Medical Protection Society) appeared for the defendant.

Mr. Neilson argued that the plaintiff's contention and the jury's finding that Mr. Harnett was sane on November 10th, 1912, showed that Mr. Harnett was in no sense under the protection of the proviso of Section 7. Being a sane man, he might at any time within the period when he was under the charge of Dr. Adam have instructed his advisers and have brought his action, but he took no steps at all to assert his right until the issue of his writ on May 31st, 1922. If it were suggested that the imprisonment had anything to do with it, even that was answered because imprisonment had been removed as a disability by Section 10 of the Mercantile Law Amendment Act, 1856. Secondly, Mr. Neilson argued that it was not the act of Dr. Fisher which brought about

Mr. Harnett's reception into a mental home, but the judicial act of Colonel Locko, the magistrate, who signed the reception order. (Everett v. Griffiths and Anklesaria [1920], 3 K.B. 163.)

Mr. Justice Horridge: If a magistrate's order cannot be obtained without first getting a doctor's certificate it shocks me to hear it said that the making of the order is not a consequence of the certificate.

Mr. Neilson: The magistrate is not bound to act on the certificate. Mr. Justice Horridge: No, he need not make an order, but he cannot make an order without a certificate.

Mr. Neilson: That the decision of the magistrate is a judicial act was held by the Court of Appeal in Hodson v. Paré [1899], 1 Q.B. 455.

Mr. Justice Horridge: It is the magistrate who acts in malicious prosecution, but it is no answer by the prosecutor to say that it was a judicial act if that act were procured by carelessness.

Mr. Neilson: The magistrate can do as he pleases with the certificates before him, and if the patient is sent to an asylum it is his act, and not that of the doctor who signed the certificate. (Williams v. Beaumont, 10 T.L.R. 489 and 543; Lock v. Ashton [1848], 12 Q.B. 871; Hall v. Semple [1862], 3 F. and F. 337.)

Mr. Cremllyn argued that Mr. Harnett came within the protection of the proviso in Section 7 because he was shut up in asylums under certificates of lunacy and could not bring any action before his release. The time for bringing his action ran from the moment when he was again at large. The jury had found that he was sane, but he was, in fact, placed in an asylum where he suffered the same disabilities as a man of unsound mind. It would bring the law into disrepute and be a monstrous travesty of justice if the man who was the cause of Mr. Harnett being placed under disabilities was to be allowed to come into court and shelter himself under the Statute of Limitations, 1623, from his own wrongful acts. Mr. Cremllyn cited Crozier v. Tomlinson, 2 Mod. R. 71; Piggett v. Rushton, 4 A. and E. 912; and Munday v. L.C.C., 32 [1916] 2 K.B. 331.

Mr. Justice Horridge, in his judgement, said he held on the authorities that a doctor who undertook the statutory duty of certifying must use reasonable care, and if he failed to do so damages so occasioned to the individual as to whom the certificate was given could be recovered against him. In this case the negligent giving of the certificate was a direct cause of the making of the reception order and of the detention. Dr. Fisher was liable for the consequences of his negligence even though the actual order under which Mr. Harnett was detained was made by the justices. Counsel for Mr. Harnett had argued that, though the jury had found Mr. Harnett was sane, and though he himself always contended that he was sane, he should be viewed as a lunatic for the purpose of construing the Statute of Limitations, 1623. He (the judge) did not think that was a correct view to take. Whether or not Mr. Harnett was *non compos mentis* was a question of fact which the jury had found in his favour, and, therefore, he was not protected by the proviso of Section 7. Originally imprisonment was among the disabilities of the proviso, but was afterwards taken out. No doubt the result of the statute might work hardship. His (his lordship's) duty was merely to construe the statute, however much he regretted the result which it forced him to reach. He must therefore enter judgement for the defendant with costs.

ACTION FOR NEGLIGENCE AGAINST MEDICAL OFFICERS.

VENN v. TODESCO AND ELDER.

Mr. Justice McCARDIE, in the King's Bench Division on April 23rd, 1926, decided that the plaintiff's action was not barred by the Public Authorities Protection Act, 1893, and the effect of this decision is that Mrs. Mary Venn, a widow, can now, if she wishes, bring a third action against Dr. J. M. Todesco, resident medical superintendent at the Croydon Borough Isolation Hospital, and Dr. J. Elder, formerly assistant resident medical officer at that hospital, for damages for the death of her husband, which, she alleges, occurred through the negligence of the defendants.

This case was first heard by the Lord Chief Justice (Lord Hewart) and a special jury in June, 1925, when the jury returned a verdict in favour of Dr. R. V. Clark, the medical superintendent of the hospital, who was also a defendant in the proceedings, but disagreed as to the liability of the remaining defendants (see BRITISH MEDICAL JOURNAL, July 11th, 1925, p. 92).

There was a rehearing on February 23rd, 1926, but the jury again disagreed (see BRITISH MEDICAL JOURNAL, March 6th, p. 459), and Mr. Justice McCARDIE proceeded to hear legal argument on the question whether the Public Authorities Protection Act, 1893, which said "the action prosecution or proceeding shall not lie or be instituted unless it is commenced within six months next after the act neglect or default complained of" applied to cases brought under Lord Campbell's Act, 1846 (which provided a remedy where a civil wrong caused death), the material words of which were: "Provided . . . that every such action shall be commenced within twelve calendar months after the death of such deceased person." His lordship decided that Mrs. Venn's action, which was brought after six months but within twelve months of the date when the deceased left the defendants' care, was not barred by the Public Authorities Protection Act, 1893, and observed that if the point before him was to be decided otherwise than as he now felt bound to decide it, that decision could apparently be given only by the House of Lords.

Sir Henry Maddocks, K.C., and Mr. B. M. Goodman, instructed by Messrs. Arthur S. Joseph and Co., appeared for the plaintiff, who sued as a poor person on behalf of herself and her two children; and Mr. A. Neilson, K.C., and Mr. T. Carthew, instructed by Messrs. Le Brasseur and Oakley, agents for Mr. J. M. Newnham, town clerk of Croydon, appeared for the defendants.

The Services.

NAVAL MEDICAL COMPASSIONATE FUND.

At the quarterly meeting of the directors of the Naval Medical Compassionate Fund, held on April 23rd, when Surgeon Vice-Admiral Sir Joseph Chambers, K.C.B., C.M.G.; Medical Director-General of the Navy, was in the chair, the sum of £165 was distributed among the several applicants.

DEATHS IN THE SERVICES.

Surgeon-General John Leslie Barrington, R.N.(ret.), died at Eastbourne on April 12th, aged 66. He was educated at the Ledwich School, Dublin, and after taking the L.R.C.S.I. in 1880 and the L.K.Q.C.P. in 1882, entered the navy. He reached the rank of deputy surgeon-general on January 26th, 1910, and retired on July 22nd, 1912, with the rank of surgeon-general. He held a Greenwich Hospital pension.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

At a congregation held on April 23rd the following medical degrees were conferred:

M.D. G. B. Bush, A. E. I. Connolly, A. C. Dixon, W. C. Douglass.

M.B. G. B. Bush, A. E. I. Connolly, A. C. Dixon, W. C. Douglass.

M.B. G. B. Bush, A. E. I. Connolly, A. C. Dixon, W. C. Douglass.

The following candidates have been approved at the examination indicated:

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.—Part I:

G. B. Bush, A. E. I. Connolly, A. C. Dixon, W. C. Douglass.

W.

R.

C.

R.

S.

R.

C.

J.

UNIVERSITY OF GLASGOW.

A GRADUATION ceremony was held on April 24th, when the following degrees were conferred:

M.D.—John Glaister, Donald McIntyre, Percy B. Farrar.

M.B., Ch.B.—The list of successful candidates was published in our issue of April 17th (p. 726).

* With honours.

The following prizes were presented:

The Captain H. S. Ranken, V.C., memorial prize of £5, awarded to the student who obtained the highest marks in the subject of pathology in the professional examinations held in the year 1925: William A. Mackey.

Bellahouston gold medal for eminent merit in thesis for M.D.:

Hugh S. D. Garven, B.Sc., M.D.

Straits Settlements gold medal for thesis for M.D. on a subject in connexion with tropical medicine or tropical hygiene: Walter Telfer.

Macleod gold medal for surgery: Edward Collier.

Asher Asher gold medal for laryngology and rhinology: William A. Mackey.

UNIVERSITY OF DUBLIN.

TRINITY COLLEGE.

At the first summer commencements held on April 24th the degree of M.D. was conferred upon F. W. Godbey.

SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have passed in the subjects indicated:

SURGERY.—N. H. C. Allen, G. H. Bickmore, S. B. Brownings, S. E.

Hyman de Tiel (Section D), C. H. St. Johnston, J. B. Lurie,

P. H. L. Moore, T. C. Pain, E. H. Rampling.

MEDICINE.—C. B. Ball, C. F. L. Haszard, A. C. Hill, J. L. Hopkins,

For H. D. Priest,

For C. F. L.

For H. D. Priest,

For H. D. Priest,

For H. D. Priest,

The diploma of the Society has been granted to Messrs. G. H. Bickmore, A. C. Hill, J. L. Hopkins, C. H. St. Johnston, D. P. Mitra, W. H. D. Priest, E. H. Rampling, J. Shibko, and J. W. Whitney.

Medical News.

At a recent meeting of the Tuberculosis Society, Dr. Neville Cox, in a paper on tuberculosis in Japan, referred to the inadequate provision for treatment in that country, there being only nine sanatoriums, with a total of 1,420 beds. The next meeting of the society will be held on May 7th, at 5.30, at Brompton Hospital, when cases will be demonstrated by the hospital staff.

The Board of Trade has informed the Chamber of Shipping that the Canary Islands are to be considered infected with plague until further notice.

PROFESSOR RICHLT has been nominated Grand Officer of the Legion of Honour.

THE annual provincial meeting of the Section of Balneology and Climatology of the Royal Society of Medicine will be held this year at Llandrindod Wells on Saturday and Sunday, May 8th and 9th. Inclusive terms have been arranged with the Pump House Hotel, and the Great Western Railway will issue week-end tickets available for particular trains. Motor trips and golf have been arranged for Saturday, and there will be a motor tour through the Wye Valley to Hereford on Sunday afternoon. Fellows and members wishing to join the party should communicate with Dr. Ackerley, Llandrindod Wells, before May 6th.

A JOINT meeting of the South-West London Medical Society and the South-West London Chemists' Association will be held at the Balham Constitutional Club, 221, Balham High Road, S.W., on Wednesday, May 5th, at 9 p.m., when Sir William Willcox will give an address on the Dangerous Drugs Acts, their application by the physician and the pharmacist.

A MEETING of the School Medical Group of the Society of Medical Officers of Health will be held at 1, Upper Montague Street, Russell Square, W.C., this day (Saturday, May 1st), at 3 p.m., when Dr. Edgar H. Wilkins, now an assistant school medical officer at Birmingham, and formerly Director of School Hygiene, New Zealand Public Health Department, will read a paper on school medical work in New Zealand. The meeting will be open to all interested in school medical work.

A SESSIONAL meeting of the Royal Sanitary Institute will be held at the Town Hall, Dover, on Friday, May 7th, at 7.30 p.m. The chair will be taken by Professor A. Bostock Hill. A discussion on experiences in diphtheria immunization will be opened by Dr. Joseph Gates, County M.O.H. Surrey, followed by Major Roberts, R.A.M.C. Dr. A. B. McMaster, M.O.H. Dover, will open a discussion on port sanitary administration.

AT a medical mission social evening on April 21st, arranged by the Society for the Propagation of the Gospel in Foreign Parts, short addresses were given by Dr. Minnie Bazely, from St. Stephen's Hospital, Delhi; Dr. H. J. Smyly, from Peking Union Medical College; Nursing Sister Mary Simpson, of St. Catherine's Hospital, Cawnpore; and the Rev. K. W. S. Kennedy, M.B. It was stated that the society required twenty-eight additional medical men and women; one in holy orders is also required for an island in the Nassau diocese.

THE two weeks' special course in cardiology at the National Hospital for Diseases of the Heart, Westminster Street, W.1, will commence on Monday, July 5th, instead of July 12th, as previously arranged.

A COURSE of lectures on physic will be given by Sir Robert Armstrong-Jones, M.D., at Gresham College, Basinghall Street, E.C.2, on May 4th and three following days. The lectures, which will be given at 6 p.m. on each day, will be on tumours and cancer, arthritis and rheumatism, venereal diseases, and encephalitis lethargica. They are open free to the public.

THE Fellowship of Medicine announces that on May 5th, at 2.30 p.m., Mr. L. E. C. Norbury will give a special afternoon demonstration at St. Mark's Hospital for Diseases of the Rectum, to which all members of the medical profession are invited. The Royal Waterloo Hospital will begin a three weeks' course in diseases of women and children on May 3rd, and an intensive course starts on the same date at the Central London Throat, Nose, and Ear Hospital, lasting until May 22nd. The course comprises clinical and operative parts, which may be taken separately. The Maudsley Hospital will give a series of lectures and demonstrations in psychological medicine during May, and another course continuing throughout the month is to be held at the London Lock Hospital. The Royal Westminster Ophthalmic Hospital will hold a course in ophthalmology from May 3rd to 22nd. Dr. Eric Pritchard has arranged at the Infants Hospital an afternoon course from May 9th to 22nd. There will be an intensive course in medicine, surgery, and the specialties at the Royal Northern Hospital from May 31st to June 12th. Other courses in June relate to diseases of children, bacteriology, diseases of the chest, gynaecology, urology, and there will be a general practitioners' course. Copies of all syllabuses and of the general course programme may be obtained from the Secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1.

THE British Institute of Philosophical Studies has arranged a course of lectures on aesthetics by Professor E. F. Carritt, M.A., during the summer term. The first, on contemporary data for aesthetics, will be given at the Royal Anthropological Institute, 52, Upper Bedford Place, W.C., on Friday, May 7th, at 5.30 p.m. Full information can be obtained from the Director of the Institute, 88, Kingsway, W.C.2.

A SERIES of debates, organized for the benefit of King Edward's Hospital Fund, is in progress on Tuesday afternoons, at 5.30, in the Great Hall of the London School of Economics. The following questions are to be discussed: On May 4th, by Miss Sheila Kaye-Smith and Captain P. P. Eekersley, "Is there too much broadcasting?" On May 11th, by Sir Ernest Benn and Mr. James Maxton, "Are capitalists overpaid?" On May 18th, by Dr. Walter Elliot and Miss Ellen Wilkinson, "Is woman becoming too obtrusive?" On June 1st, by the Right Hon. J. H. Thomas and Mr. G. K. Chesterton, "Is the House of Commons of any use?" Tickets and further information may be obtained from the Secretary, London School of Economics, Houghton Street, Aldwych, W.C.2.

THE nineteenth Voyage d'études médicales, postponed from last year, will begin next August. It is organized by Dr. Maurice Gerst, under the scientific direction of Dr. Paul Carnot, professor of therapeutics in the Faculty of Medicine of Paris, and Dr. Harvier, professor agrégé in the same faculty. The party will visit Alsace, Lorraine, and the Vosges. It will assemble at Nancy on the morning of August 29th, and after visiting the antituberculous and thermal establishments, the hospitals and the Faculty of Medicine there, will go on by Morshonn and Niederbronn to Strasbourg, where the third day will be spent. Leaving there on September 1st it will visit various institutions on the way to Kilsauville and Colmar. On September 4th, after again visiting various institutions on the way, it will reach Plombières in the evening. On September 5th it will go by Bains-les-Bains to Bonnefontaine-les-Bains. On the ninth day, September 6th, it will reach Contrexéville, and the tenth day will be spent at Vittel, where the party will disband. The cost of the trip, including all expenses from Nancy to Vittel, will be 1,050 francs. British doctors desiring to take part in the voyage should communicate without delay with Madame M. C. Juppé-Blaise, at the Office Français du Tourisme, 56, Haymarket, London, S.W.1. Participants who wish to visit the battlefields of Lorraine and Verdun can do so on August 28th, but must arrive at Nancy on the evening of August 27th.

THE eighteenth Congress of Russian Surgeons will be held at Moscow from May 27th to 30th, when the following subjects will be discussed: (1) Radical operation for inguinal and femoral hernia, and its remote results, introduced by Professor Martynoff. (2) Affections of the spleen, indications for splenectomy and its remote results, introduced by Professor Herzen of Moscow. (3) Surgical treatment of jaundice from retention, introduced by Professor Fédoroff of Leningrad.

THE annual dinner of the Metropolitan Police Surgeons' Association took place at the Holborn Restaurant on April 22nd. The president, Dr. Percy B. Spurgin, received the guests and presided at the dinner. Among the numerous company who attended were the Commissioner, Sir William Horwood; the Assistant Commissioner, Colonel Lantier; the Chief Surgeon, Sir Charles Ballance; the Chief Physician, Dr. Cassidy; Mr. H. W. Wilberforce, Deputy Chairman London Sessions; and the Mayor of Croydon. The speeches were well received, and the company much enjoyed an excellent musical programme. About a hundred divisional surgeons and their friends were present, and the evening was a great success.

THE dinner of the St. Andrews University Former Students' Club will be held at the Royal Hotel, Princes Street, Edinburgh, on Friday, May 21st, at 7.30 p.m. The charge for the dinner is 6s. 6d., and any former students desiring to be present, or to join the club, are requested to communicate with the Rev. G. Christie, B.D., 2, Heriot Row, Edinburgh.

THE Home Secretary gives notice that he has withdrawn from Dr. Samuel Grahame Connor, of 21, Dryden Chambers, Oxford Street, London, the authorizations granted by the Regulations made under the Dangerous Drugs Act, 1920, to duly qualified medical practitioners to be in possession of and supply raw opium and the drugs to which Part III of the Act applies. Any person supplying Dr. Connor with raw opium or any of the drugs to which Part III of the Dangerous Drugs Act, 1920, applies will be committing an offence against the Act.

MR. P. G. DOYNE, F.R.C.S., assistant surgeon Royal London Ophthalmic Hospital, sailed for America on April 24th with a team of British fencers chosen to represent Great Britain in the competition for the trophy presented by Colonel Robert Thompson, which is fought for alternately in England and America. Mr. Doyno has twice won the British Amateur Foils Championship.

A REVISED edition of his *Stellar Songs and other Poems* has been issued by Dr. Herbert A. Smith. The main poem is a metrical study of stellar evolution based on the nebular hypothesis; the other contents include sonnets, miscellaneous verses, and an essay on science and poetry.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9561, 9562, 9563, and 9564** (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR of the **BRITISH MEDICAL JOURNAL**, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscru Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Burillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

QUERIES AND ANSWERS.

SACRO-ILIAC PAIN.

DR. S. W. RHODES (Scarborough) asks for help in the following case: A man aged 29, who has been suffering from acute rheumatism for three months, has severe pain in the sacro-iliac joint, and relief can only be got by the use of Dover's powder (75 grains a day). He has had treatment of all kinds—from salicylates to electric massage and radiant heat; x-ray examinations, both of the sacro-iliac joint and sigmoid colon, are negative.

VULCANITE.

"J. S." asks: What industrial diseases, if any, arise in workers at vulcanite works? Is it likely that any form of paralysis is contracted in the course of this occupation?

"We have referred this question to an authority on industrial medicine, who, however, is unable to give a reply from personal experience. Since the introduction of wireless and its widespread use, the output of vulcanite has much increased. During the boring of vulcanite a most unpleasant odour is emitted, and as the smell may be due to dust some of this may be inhaled, but our adviser has not hitherto heard of any ill effects to the workers arising therefrom.

WHAT IS A "MORPHINE ADDICT"?

DR. G. WASHINGTON ISAACS (London, W.C.) asks for a definition of a "morphine addict," and adds: I have a patient who suffers from asthma and who can generally control his attacks with adrenaline, but every few weeks he comes to me for heroin and I give him three or four tablets 1/12 gr. in each. I have another patient who suffers from tabes dorsalis, and occasionally gets a severe attack of lightning pains. On one occasion he shouted loudly and disturbed his neighbours at intervals of less than a minute for about sixty consecutive hours. This man requires morphine, and two tubes of twenty tablets 1/4 gr. last him five or six months. He will not take morphine if he can avoid it, as it invariably makes him vomit. Are these cases morphine addicts and am I liable to punishment by law and subsequently to the wrath of the General Medical Council? Must I keep a record of the heroin supplied and the morphine tablets with me if I am called out to a case which seems likely to require a sedative? Or, if called to a case of acute mania, may I take it even though it contains morphine as well as hyoscine? I ask these questions in all seriousness.

"A careful study of the report of the Departmental Committee on Morphine and Heroin Addiction, 1926, will at once remove our correspondent's fears. A fairly full analysis of the report was published in the **BRITISH MEDICAL JOURNAL** of February 27th (p. 391), but the report itself can be obtained from H.M. Stationery Office, Adelphi House, Kingsway, London, W.C.2, price 1s. An addict is defined in the report as—

"A person who, not requiring the continued use of a drug for the relief of the symptoms of organic disease, has acquired, as a result of repeated administration, an overpowering desire for its continuance, and in whom withdrawal of the drug leads to definite symptoms of mental or physical distress or disorder."

Neither of the patients mentioned is an addict, so there is no

risk of any censure or penalty from either the law courts or the General Medical Council. It is quite safe to take—and to use if necessary—a hypodermic case to a patient with acute mania or to anyone likely to need a sedative. Section III of the report sets out in detail the circumstances in which it may be medically advisable to administer morphine or heroin to persons known to be suffering from addiction to these drugs, and Section IV deals with the precautions to be observed in the administration of morphine or heroin. For his own guidance and protection every practising physician should make himself familiar with these very important matters. The regulations issued under the Dangerous Drugs Act make it compulsory to keep a record of any of the scheduled drugs, including heroin, supplied, but there is no obligation to keep any record of morphine or the other drugs if they are prescribed or personally administered.

INCOME TAX.

Motor Car Expenses: Irish Free State.

"J. C." writes from the Irish Free State explaining that his son has given him a motor car because his old car is worn out, and asking what allowance he can claim.

"We fear that at present he cannot claim any allowance. He has not incurred expenditure in replacing his old car—apart from the fact that the new car was a gift, he still retains the old one—and the Free State has not yet followed the example of the British Parliament in providing for a depreciation allowance in respect of cars used for professional purposes. "J. C." might perhaps keep the latter possibility in mind as regards 1926-27.

Partnership: Car Expenses.

"LEX."—A and B hold half shares in a practice, and the income tax authorities insist on deducting the combined expenses of running their cars from the total receipts of the practice. Is this correct?

"Yes. The firm is assessable as such, and the partners are not entitled to be assessed separately. The result is inconvenient, and the Association represented that fact some years ago to the Royal Commission on the Income Tax. We advise "Lex" to enlist the assistance of his inspector of taxes, if possible—if the detailed figures have been supplied to him—or, alternatively, to recalculate the three years' average for each partner separately agreeing the aggregate with the actual assessment.

LETTERS, NOTES, ETC.

A WARNING.

The Secretary of the Medical Defence Union asks us to state that he has been informed by a member of the Union residing in Birmingham that recently a man brought in a parcel of books, stating that the member had ordered them from W. H. Smith and Sons. At his request he was paid £1. The parcel contained some novels which had not been ordered. The member was informed by the Birmingham police that a man had been working this trick in various parts of the country and that a warrant was out in several towns for his arrest. He is described as about 30 years of age, medium height, slight dark moustache, fairly well dressed, and wearing a brown overcoat.

POISONING BY THE PRODUCTS OF COMBUSTION OF TOBACCO.

DR. HOWARD B. GLADSTONE (London, S.E.) writes: The case of a child poisoned by the juice of an old pipe rubbed into the skin, reported in the **BRITISH MEDICAL JOURNAL** of April 24th (p. 739), can be matched by that of a little boy of 16 months I saw recently, who got the poison in by his mouth. He was allowed to put a dirty old pipe in his mouth and pretend to smoke it for the amusement of his parents. This was at 6.30 p.m., and after half an hour he was put to bed apparently in good health. At about 7.30 he was seen to be uneasy and to be very pale, and shortly after he began to vomit. He looked very bad and the vomiting was persistent; by the time I saw him, about 10.30 p.m., he had vomited seven times. He was then beginning to revive, and as his temperature was normal, his abdomen and muscles generally relaxed, it was evidently a case of nicotine poisoning, from which he was just recovering. I saw him next morning and heard that he had not been ill after I left, and he was playing about as if nothing had happened.

ERRATUM.

We regret the error on page 753 of last week's issue of the **JOURNAL**, in which a tuberculosis hospital scheme was attributed to "Portsmouth," instead of "Plymouth."

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 32, 40, 41, 44, and 45 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 42 and 43. A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 177.

A Lecture

ON

THE PRINCIPLES INVOLVED IN PROPHYLAXIS
AND THERAPY BY MEANS OF VACCINES.*

BY

J. C. G. LEDINGHAM, C.M.G., D.Sc., F.R.C.P., F.R.S.,

PROFESSOR OF BACTERIOLOGY IN THE UNIVERSITY OF LONDON;
CHIEF BACTERIOLOGIST, LISTER INSTITUTE.

HAD my subject been merely that of prophylaxis by means of vaccines, I should have felt myself in a fairly strong position in coming before you, as prophylaxis rests on strong scientific foundations, and has in practice proved its merit. I must, however, claim your indulgence in my discussion of vaccine therapy because my clinical experience of it has been strictly limited and my interest in it has been largely confined to the immunological problems it offers. On the other hand, I take refuge in the reflection that, though vaccines have been exploited in treatment for, I should say, over twenty years, the accumulated clinical data as to their efficacy or otherwise have not yet supplied that decisive link in the evidence which would raise vaccine therapy from the level of a purely empirical practice. What I mean is that any scientific basis on which specific vaccine therapy may rest has not been enlarged and built upon by decisive experiment on man or animals, and the consequence has been that vaccine therapy continues on its hapless way, exploiting now this, now that purely technical modification, but really in no way consolidating its position as the form of specific therapy which it has been believed to be.

I would explain how the matter appeals to me, regarding the introduction of bacterial vaccines solely as a means calculated to raise the natural defences of the body, and really based on immunological experiment, but gone somewhat astray in its application to therapy. I propose, therefore, to disentangle from the ravelled accumulation of data on vaccines just those elements which rest on experimental fact. I do so in the hope that the practitioner may be constrained also to test his vaccines and interpret his results in such wise that he will gain comparative knowledge from the experience. I freely admit that in general practice conditions are far from suitable for procuring reliable comparative statistics with regard to the efficacy of vaccines, or in fact of drugs generally. Only few have the time or inclination to amass comparative statistics that may mean real additions to knowledge, but I believe much may be gained by frank discussion of the effects which vaccines are claimed to produce in therapy, and this I propose to do. Let me, then, trace briefly the origin and development of the use of vaccines in prophylaxis and therapy, confining myself solely to experimentally ascertained facts. I start naturally with prophylaxis, and may probably end with prophylaxis, because I hope to show that much of what is called specific vaccine therapy is simply a form of prophylaxis, and what is not prophylaxis is simply a form of non-specific protein therapy—bacterial protein therapy if you like, it is immaterial.

PROPHYLAXIS BY VACCINES.

Prophylaxis of infectious disease by means of vaccines I must deal with only shortly, as, apart from vaccination against small-pox, the method does not enter largely into the sphere of the general practitioner, at least in this country. The use of the living attenuated virus remains with us only in the prophylactic methods developed by Jenner and Pasteur against small-pox and hydrophobia. In certain veterinary diseases, however, the methods of Pasteur, or modifications of them, still find practical application, and there would seem to be little doubt that only by means of the attenuated live viruses is it possible

to secure solid immunity against certain highly virulent infections in highly susceptible animals. The axiom that the live virus is the one most calculated to give solid immunity as tested experimentally by a lethal dose method is not to be lost sight of in the prophylaxis by dead vaccines of human bacterial infections. In a recent Harben lecture I have discussed the position of enteric fever prophylaxis, which was worked out almost solely on data concerning antibody production in animals (especially bactericidins) elicited by typhoid antigen. We now know that immunity, as measured by capacity to withstand an otherwise lethal dose of infection, is not necessarily correlated with the antibody content titratable *in vitro*. The fundamental difference between an immunized animal whose antibody content has fallen to normal levels and an untreated normal animal is that in the former the injection of a minute dose of antigen elicits a prompt and massive response of the antibody mechanism, whereas in the latter the response is slow and meagre. Some doubt has been expressed of late as to whether we can hope with dead vaccines to secure that degree of immunity which the attenuated virus can afford. The question can be answered only by animal experiment. Even though the causative agents of human disease, such as the enteric and paratyphoid fevers, cholera and dysentery, cannot reproduce with any exactness the symptom-complex of the human disease, they possess sufficient pathogenicity to make the lethal dose test of immunity a valuable criterion of the immunizing capacity of antigen. It is believed by some workers that the defects of the killed antigen can be made good by increase of dose. This may prove to be so, but at the present time new ground is being opened by advances in our knowledge of bacterial variation, and the choice of a suitable variant as the source of antigen may become the all-important factor in securing solid immunity with killed vaccine.

VACCINE THERAPY.

Vaccine therapy was in its origin really a development of vaccine prophylaxis applied to the more chronic types of infection. We must go back a little more than twenty years to find bacteriologists and clinicians eagerly investigating the claims of opsonic index determinations as guides to the state of immunity of the individual, whether normal or infected. It had been known that while certain organisms like the typhoid bacillus or the cholera vibrio were susceptible to lysis in the presence of immune serums, such organisms as the staphylococcus or the streptococcus, and many others, were not killed in the presence of serum prepared from animals immunized with these organisms. Denys and Leclef, however, found that when organisms like the staphylococcus or streptococcus were placed in contact with leucocytes and immune serum they were eagerly phagocyted. Some substance in the immune serum, to which the name "tropin" or "*substance sensibilisatrice*" was given, prepared the organism for phagocytosis by the leucocyte.

Opsonins.

Later Wright and Douglas showed that normal serum contained a body having the same property, and though the new name of opsonin was coined for it, it was demonstrated, as the result of much experiment devoted to the question, that the normal opsonin was in no way separable from the immune opsonin in structure and function. The name, however, has stuck, and it is quite a good name. Wright decided that the estimation of opsonin in the infected individual might afford an index of the degree of immunity in staphylococcal infections just as the bactericidal power of the serum had been used as a guide in estimating the development of immunity to *B. typhosus*. The method failed as a practical guide in immunization, and, I think, has been entirely given up. Its failure was largely due to the fact that it was overexploited as a practical guide and scientific claims were made for it as a quantitative index of immunity which were not merited. Moreover, at the time, it was not realized that non-specific factors entered largely into the matter, leading either to rise or depression of the opsonin content. I shall come to this presently.

* Delivered to the Croydon Division of the British Medical Association, February, 1926.

One point on which great stress was laid was the occurrence of a negative phase after the injection of a vaccine, and much was made of the alleged dangers of producing too severe negative phases by overdosage and of the alleged lowered resistance of the individual during these phases. It was noted that after a dose of vaccine there was a primary fall in the index followed by a rise, reaching its acme about the end of the first week. Now we know that a temporary fall in antibody follows regularly the introduction of a dose of antigen. It is probably to be explained on physico-chemical grounds as one of the effects following the injection of a colloid. It cannot be adequately explained as the result of abstraction of antibody by the antigen injected. This fall in the opsonic titre Sir Almroth Wright brought into relation with certain focal or general reactions liable to occur at early periods after the administration of a vaccine. Thus, to take an example from his *Studies in Immunisation*: A patient suffering from boils was given a dose of staphylococcal vaccine. On the following day the patient's phagocytic power was found to be reduced. "Contemporaneously with the development of this 'negative phase' an irritable pimple developed on the neck. We may see in this, for it is a phenomenon which has manifested itself again and again in connexion with our inoculations, an indication that the negative phase is associated with a diminished resisting power to invasion by the staphylococcus." I dare say the phenomenon of focal reaction is well known to all of you.

From such considerations as these was built up a practice of immunization which was regarded as applicable with safety to the patient only when the system of dosage was controlled by periodical estimations of the opsonic index. Only the trained immunizer was to be entrusted with the task. Now we know, of course, that fearful things did not happen when the opsonic control was left out. Further, it came to be realized that variations in opsonic content bore little or no relation to the clinical state which is all we have to depend on for an estimate of the host's reaction to an existing infection. However, I may say that for a good many years now therapeutic immunization has proceeded on certain fairly stereotyped lines, commencement being made with doses of a killed organism which experience has shown to be relatively innocuous and passing on at fairly uniform intervals to larger doses, the only guide to treatment being the patient's responses and common sense.

I do not propose to discuss the value and results of this alleged specific therapy. I can only repeat what I have been credibly informed—namely, that in certain more or less acute infections like furunculosis, where the effect of any treatment can be very correctly estimated, vaccine treatment has in the main made good. Vaccine treatment of furunculosis might probably rank as a specific therapy, but not as a specific staphylococcal therapy seeing that vaccines of *B. coli* or of *B. typhosus* have been shown to act similarly on furunculosis. In other types of chronic infection—for example, chronic gonococcal infection or bacillary cystitis—vaccine therapy may claim to exert specific action, but it is doubtful whether there is any unanimity among clinicians on the point, and we have no other source of precise information.

When we consider, further, the many other forms of chronic infection, such as the respiratory and arthritic affections, in which vaccine therapy is widely used, we feel ourselves to be almost entirely in the realm of pure empiricism because we have no certain knowledge of the etiology of these infections. In the respiratory group recourse is had to vaccines prepared from the mixed flora multiplying and presumably doing harm in the affected region. In arthritic affections, again, it may be expedient to prepare vaccines from organisms vegetating in situations still more remote from the clinical side of the trouble—for example, from faecal streptococci—on the chance that they may be concerned with so-called intestinal intoxication, which again may be associated with, shall we say, rheumatoid arthritis. In fact, all we can really say about such vaccines is that they consist of bacterial protein. Now we know that, apart from antibody response, the introduction of bacterial protein into the body is followed by a chain of intensely

interesting physiological phenomena; some of these I propose to discuss, so that we may get back to really basic principles. The first point I must make is that vaccine therapy does not lend itself readily to experimental investigation in the laboratory. Chronic infections which would afford scope for therapeutic treatment by vaccines are not easily induced, with the notable exception of tuberculosis. Acute infections in laboratory animals are usually too acute and of too short duration to render vaccine trials possible. We have therefore to resort to experiment on normal man and animal, determining the effects exercised by bacterial protein injections on antibody content, the fluid and cellular constituents of the blood, body temperature, blood pressure, etc.

Non-specific Protein Therapy.

On these points a mass of data is now available which helps us to understand something of the mechanism of action of bacterial protein when introduced into human beings. Let me go back to the days of the opsonic index. An investigation I then undertook, in collaboration with Professor W. Bulloch, was on the influence of experimental leucocytosis on opsonic content. Of various substances employed to produce a leucocytosis experimentally, such as nuclein, sodium cinnamate, tallianine, etc., the first mentioned was the only one which in addition produced a very notable temporary increase in opsonin (50 to 100 per cent.). This increase made its appearance within an hour of injection, and was generally gone by twenty-four hours. It was entirely a non-specific rise, and quite irrespective of the organism employed to demonstrate it. Also autolysed bacterial protein had the same effect as nuclein. The phenomenon was later investigated by Bedson, but it was found impossible to explain it in terms of increased amboceptor or of complement. It is highly probable, in the light of later work with colloids, that this prompt variation in normal antibody following the introduction of substances like nuclein, or any autolysed bacterial protein, comes into the category of those purely physiological phenomena which the injection of a colloid can induce. In any case, it was this apparently non-specific early variation in antibody induced by nuclein and autolysed bacterial protein which led me to believe that many of the immediate effects of vaccines, such as the early euphoria, the sometimes startling clinical improvement, and the focal and general reactions, were disturbances which had their source in the colloidal nature of the vaccine.

I may say that while this view has long been held by many immunologists it will have been observed that only recently Sir Almroth Wright has thrown overboard the principle of specific vaccine therapy in the old sense, at least so far as the treatment of acute septicaemic infections by vaccines is concerned. His method of immunotransfusion is, in part at least, an attempt to administer passively to the patient the antibodies which the injection of substances like nuclein or bacterial protein can rapidly induce in a normal person. We have, however, a large body of evidence on the point. It was noted many years ago that an intravenous injection of typhoid vaccine in typhoid fever frequently brought the temperature down promptly and the febrile state ceased, leading to rapid convalescence. Soon, however, came the demonstration that an injection of *B. coli* vaccine, or indeed of substances like casein or deuto-albumose, could do precisely the same thing in typhoid fever. The exact mechanism is not yet understood. We know that in the normal animal a pyrogenic effect is produced by the intravenous injection of a minute quantity of bacterial protein. It is suggested that when a similar injection is made in a case of typhoid fever already febrile, the heat centre is paralysed and the temperature falls. Why it does not again rise is not clear, and doubtless there are other physiological effects apart from that on temperature which follow the injection of colloids in the infected subject. In any case, we now know that focal reactions are not produced by the specific antigen only. In chronic gonococcal infections precisely similar focal reactions can be induced by other antigens than the gonococcal, and by still less specific agents such as casein or milk. Similar considerations apply to the

treatment of rheumatoid arthritis by injection of non-specific proteins.

We have no precise knowledge of the actual mechanism of these focal reactions in the infected subject, though many hypotheses have been put forward. It is generally believed that the ultimate effect in any case is to produce a greater flow of blood through any indolent inflammatory foci that may be present, with the result that the normal cellular and humoral defences are allowed to come into play. Possibly it accomplishes for the unseen indolent lesion what the surgeon's bistoury does for the visible carbuncle.

Non-specific protein therapy has really a very long history if all the phenomena provisionally assigned to this category do rightly belong to it. We have the mutual interaction of concurrent infections with the onsting of the more chronic by the more acute as evidenced by observations on erysipelas supervening on more chronic processes. The use of Coley's fluid was an attempt to apply this principle to the treatment of sarcoma. The experimental induction of malaria for the amelioration or cure of general paralysis is another instance of prolonged and repeated protein shock therapy. So also is the Schiötz treatment for diphtheria carriers which would seem to depend for any attendant success on the inflammatory reaction produced by the staphylococci sprayed on the throat. Many other phenomena, such as the occasional dramatic effect of normal horse serum in septicaemias, the use of auto-serotherapy and of multiple bleedings, come probably into the same category.

I conclude, therefore, that so far as the early effects (euphoria, focal and general reactions, etc.) following an injection of vaccine are concerned, the action is entirely non-specific. There is no warrant for assuming that the organism, a vaccine of which happens to give a focal reaction in a particular case, is etiologically related to the case. One bacterial colloid can be more potent than another in the production of immediate physiological effects.

In many cases it is the action of the non-specific element of the vaccine that we wish to elicit with a view to cure. This is certainly so in the acute infections and in the more chronic infections (for example, the arthritic) also; we gather that the object now usually aimed at is to produce focal and general reactions by repeated administration of non-specific substances in appropriate dose.

Vaccine therapy, however, as ordinarily practised, involves the repeated injection of a vaccine with a view, not only to cure of an existing infection, but also to prevention of subsequent infection, and here vaccine therapy and vaccine prophylaxis meet on common ground.

Theoretically, therefore, as in ordinary vaccine prophylaxis, specificity of antigen must, at least in our present state of knowledge, be the highest possible if we are to expect the best results. The difficulty arises in preparing a vaccine that can be regarded as specific in many of the affections for which vaccines are used. Valuable information on this point may be expected from those recently organized attempts to control the prevalence of respiratory affections in boarding-schools and institutions by prophylactic vaccines. It is greatly to be hoped that these efforts will be so directed that comparative knowledge may be gained on many important particulars—such, for example, as the qualitative and quantitative vaccine formulae.

SUMMARY.

To sum up briefly what I have put before you, I have emphasized the importance of the non-specific element in vaccine therapy in its purely curative aspect, without ignoring the possible benefits that may accrue from repeated vaccine administration with a view to prophylaxis. I should like to say, however, that in giving my impressions of the rationale of vaccine therapy I have merely been elaborating views that have long been entertained by immunologists but have, I believe, not been adequately ventilated among those who daily practise the method. My object has been achieved if what I have said may help the practitioner to view his aims and achievements in vaccine therapy from a somewhat less conventional angle.

ON THE CONTROL OF HEART DISEASE IN CHILDHOOD.

BY

MARGARET F. LOWENFELD, M.R.C.S., L.R.C.P. (Eng.)

(From the Medical Department, Royal Hospital for Sick Children, Glasgow.)

ONE of the most serious issues presented to practical medicine to-day is the problem of cardiac disease in the young. By the estimate of Dr. Carey Coombs¹ the onset of two-thirds of our adult cardiac morbidity occurs during the period of life from 5 to 15 years of age. Dr. Askins states that we are losing 18,962 lives per annum from this cause alone, and there must not be forgotten in this connexion "long periods of illness, the misery of repeated breakdowns, and the immense industrial loss involved during the years which elapse between the time when the patient develops the disease and when he is ultimately killed by it,"² if we are to gain an idea of the magnitude of the problem involved.

It is now generally admitted that carditis in childhood is for all practical purposes a rheumatic manifestation; the problem of carditis is thus synonymous with the problem of rheumatism, and in practice the control of heart disease in childhood means the control of the rheumatic child. For this outlook on the question the British Medical Association is in no small measure responsible, and from the illuminating discussions of the whole question arranged by its Sections of Medicine, Diseases of Children, and Public Health in 1923 and 1925, a very considerable body of information has emerged relating to the manifestations of the disease itself and the available agencies for coping with it. A consideration of these discussions brings out clearly that rheumatism is an exceedingly long-drawn-out and chronic infection, which in all its forms should be considered as passing through three stages—the acute, the convalescent, and the quiescent. To be effective, therefore, any attempt at control of the disease must take cognizance of each of these, and be directed along three definite lines.

1. The Acute Stage.

That a very significant diminution in the incidence of carditis can apparently result from efficient handling of this stage has recently been brought out by Dr. Bertram³ in a survey of the after-history of cases treated at the Royal Hospital for Sick Children, Glasgow. She showed that whereas only 24 per cent. of those treated in hospital for their first attack of acute rheumatism or chorea subsequently developed carditis, this sequel occurred in 88 per cent. of those who were treated at home. This is the stage most easily reached by our present organization, and there seems no valid reason why the children's hospitals and the children's departments of the general hospitals at present existent could not satisfactorily cope with it so long as provision can be made to ensure a sufficient length of residence.

2. The Convalescent Stage.

Upon a satisfactory convalescence depends the child's chance of recovery from rheumatic fever or chorea without damage to his heart. The two essentials are: an adequate period of rest and a graduated return to ordinary conditions of living. Treatment of this stage of the disease, therefore, entails the adequate provision of convalescent homes or rest hospitals in sunny and dry areas, where children can receive medical supervision, graduated exercise, and suitable education.

3. The Quiescent Stage.

After the acute and convalescent stages have passed there is a further phase of the disease, extending over many years, and during which the possibilities of recurrences are always present. The very essence of the rheumatic infection is its chronicity and great tendency to relapse, and this third stage, which may be called the "quiescent stage," since no active manifestations are present, is of the greatest significance in any scheme for prevention. It will be readily understood that it is neither feasible nor desirable that this period should be passed in

hospital, yet it is during this time that need for watchfulness is greatest if the tendency to relapse is to be controlled.

It is here that the failure of our machinery is most apparent. While exhaustive and skilful care is expended upon the acute cases in our wards, and while public opinion is wakening to the need for further facilities for convalescents, no adequate provision exists for the vaguely rheumatic child, the child in the pre-rheumatic stage, and the child between his definite acute attacks.

In America a serious attempt has been made to tackle this side of the problem, and through the initiative of the Society for the Prevention and Relief of Heart Disease special classes (called cardiac clinics) have been erected for the purpose. These provide continuous supervision for the rheumatic child during the whole of his pre-puberty life. American results show that by means of this kind of supervision the work of hospitals and convalescent homes can be conserved and so supplemented that a very large number of children and young persons can be rescued from the ranks of invalidism and returned to normal life.

An organized attempt to carry out such a scheme was inaugurated by William St. Lawrence⁴ of St. Luke's Hospital, New York, in 1915. Stimulated by his record of the results obtained, an experimental clinic on the same lines was instituted at the Royal Hospital for Sick Children, Glasgow, as part of the medical department, in December, 1923. The aim of the clinic was to find out how far such supervision was practicable under British conditions, to what degree and by what means carditis in the children supervised could be prevented, and to devise a system of registration which should provide material for further study of the disease. The children attending the clinic had all been at one time resident in the Royal Hospital for Sick Children for attacks of acute rheumatic fever, chorea, or carditis, and formed part of the material used for an etiological and sociological survey carried out by Dr. Sutherland and myself, under the auspices of the Medical Research Council, in 1923-24.

CLASSIFICATION OF CASES.

For the proper conduct of such a clinic a satisfactory and practicable classification of the children supervised is a fundamental requirement. St. Lawrence classified his cases according to their cardiac efficiency, which he held could be satisfactorily estimated by means of the child's tolerance to exercise, and in his description of the clinic he details the special exercises adopted. Such a method of measuring cardiac efficiency we found, at least in the children coming under our care, not to be practicable, and we entertain grave doubts if any exercise can be performed by every child with sufficient concentration and uniformity to render it an adequate basis for classification. Before deciding, however, to abandon St. Lawrence's procedure a number of experiments were carried out, not only with the "Levis class exercises" recommended by St. Lawrence, and with other similar tests, but also by means of an ergograph and the spirometer. In the case of the latter two methods, the reactions of both normal and cardiac children were investigated. The results of these demonstrated to us the inadvisability of placing reliance upon any such tests for general use with young children. We therefore devised in its stead the following simpler classification embracing seven groups, based on the past histories of the children and the present cardiac findings by ordinary clinical methods. Upon this classification the whole work of the clinic depends. It is as follows:

CLASS P. Potential heart cases—that is, cases with definite rheumatic history who have never had cardiac involvement and are now well.

CLASS A. Cases with a history of definite rheumatism with cardiac involvement, which has now disappeared.

CLASS B. Cases with a definite rheumatic history and present signs of cardiac involvement but no symptoms referable to the heart.

CLASS C. Cases with a definite rheumatic history and present signs and symptoms of cardiac involvement but no disability for ordinary life.

CLASS D 1. Cases with a definite rheumatic history, present signs and symptoms of cardiac involvement, and definite disability for ordinary life.

CLASS D 2. Cases without a rheumatic history, but showing

signs of a cardiac lesion, and with some definite disability for ordinary life (fainting, dyspnoea, precordial pain, etc.).

MISCELLANEOUS. Cardiac irregularities, effort syndrome, erythema nodosum, and cutaneous eruptions supposed to be of rheumatic origin.

The actual carrying out of the work is as follows. The clinic meets once a week, at a time which does not interfere with the children's school attendance, in an ordinary room of the hospital. No special apparatus beyond a weighing scale is used. Upon the arrival of a new child at the clinic he is stripped and his weight, temperature, and pulse are taken; these are entered on a slip of paper, with which, still undressed, he approaches the doctor. For each child there is a complete clinical sheet, on which an abstract of his previous health and his hospital record have already been entered, with due note taken of the method by which he was treated in the wards. Complementary to this is a social record kept by the lady almoner which deals with the whole of the social side of the case. For convenience of reference these two are printed in different colours but filed together.

A complete examination of the child follows, with special attention to teeth, tonsils, stance, presence or absence of anaemia, state of the bowels, and general health. The mother is then interviewed, and points with regard to habits, etc., considered. Consultation with the almoner disposes of such matters as efficiency of clothing, holidays, trouble with school teachers, etc. The child is now graded, the degree for the present provisional, and treatment is begun. This is directed towards the clearing up of all septic foci in the body, the establishing of satisfactory and regular bowel actions, and where possible the rectification of unsatisfactory habits. Arrangements with the throat department make possible the prompt care of all suspect throats, and every throat not entirely normal is passed to this department for examination. All carious teeth, irrespective of dentition, are attended to, and no child of whatever age is allowed to retain a spot of caries in its mouth. All bowel irregularities are supervised and the child kept under observation until action has become satisfactory. If desirable and possible a holiday in the country is arranged for. Clothing is inspected, particularly boots, and where possible rectified. Home conditions are uncontrollable, but what modifications are possible are attempted, and pressure brought to bear with regard to regular meals, sleep, exposure, etc. Relations with school teachers are inquired into and where—as for example, in the case of those children suffering from chorea—these are unfortunate, co-operation with the school board can often bring about an improvement in affairs.

As regards drugs, a consideration of the relative efficiency of the different remedies from the standpoint of carditis has already been made by Dr. Bertram, and the superiority of salicylates, in our opinion, definitely shown. Sodium salicylate, therefore, forms the basis of all medicinal treatment in the clinic, and upon the reappearance of any rheumatic manifestations whatever a course of sodium salicylate is instituted. Even young children, it is found, can bear courses of 60 grains per diem with ease, provided it is combined with double the amount of sodium bicarbonate and precautions are taken against constipation. The mother of any child on sodium salicylate is advised as to the appearance of symptoms of intolerance, and instructed to suspend the drug for forty-eight hours on their occurrence. During the carrying out of all these procedures the child attends at the clinic when necessary. As soon as everything has been done that can be done, a further careful cardiac examination is made and a definite class assigned to the child. Under this letter he is registered, and on this his future attendance at the clinic depends. The intervals at which children attend the clinic are as follows:

Class P children	at intervals of	4 months
Class A children	"	3 "
Class B children	"	6 weeks
Class C children	"	4 "
Class D 1 and D 2 children	"	2 "

Attendance of Classes C, D 1, and D 2 vary greatly according to their condition, but upon a uniform basis of four and two weeks. Having once been graded the child attends according to his class, and at each subsequent

attendance the same procedure obtains. To facilitate the routine a rubber stamp has been prepared, giving the essential headings under which examination of the child is made. The use of this outline standardizes the record and ensures no point being forgotten.

It is the work of the almoner attached to the clinic to keep the attendance record in order and to notify the mothers, since the whole basis of the work rests upon systematic and regular attendance. No effort is spared to impress this fact upon the mothers and to secure their co-operation. A careful explanation of the importance of this point is always given at the clinic to each mother, and the reasons for the exact interval of attendance required for her particular child explained to her. Any mother has the right to bring her child to the clinic, whether in or out of her turn, if she fears the recurrence of trouble. After a time it has been found possible with nearly all mothers to gain their warm co-operation. Specially marked is the effect of this upon the general welfare of the children. Feeling that an interest is being taken in the child, as a rule the mother responds with an all-round improvement in care, as much in the points which have not been commented on as in those that have, and it is to this that a good deal of the results of the clinic can be attributed. In cases where prolonged effort has failed to secure the co-operation of the mother, either in the matter of attendance or in any of the procedures recommended by the clinic, the child's name is erased from the list.

To carry out the work of the clinic the staff for 1923 to 1924 consisted of one doctor, a lady almoner delegated to the clinic from the almoner's department, and a nurse. An assistant doctor and a voluntary visitor have since been added.

RESULTS OF THE CLINIC.

As the clinic has only been in existence for two years it is impossible to draw any far-reaching conclusions, but the following brief analysis of the first year's work is of interest and shows the value of such a department.

Total number of cases dealt with (57 girls, 36 boys)	93
Number discharged through lack of co-operation...	9
Number discharged as being too old	3*
Number transferred to home for chronic cases (since recovered)	1
Number transferred to other clinics	1
Number remaining on register	79
Number of meetings of clinic	48
Average attendance at clinic	8.2

* No children over 13 years are admitted to the Royal Hospital for Sick Children, Glasgow.

The cardiac condition of the children according to the above classification on their admission to the clinic was as follows: P, 26; A, 30; B, 23; C, 9; D1, 1; D2, 2; Miscellaneous, 2.

The fate of these children during the period under review was as follows: Recovered 5, improved 1, developed cardiac lesion 2 (moved to Class B), disabled 1 (since recovered), *in statu quo* 70. These changes in classification of the children are shown in detail in the following table.

Improved.

Cases moved from Class C to A	1
Cases " " Class B to A	4
Cases " " Class C to B	1

Worse.

Cases moved from Class P to B	1
Cases " " Class A to B	1

It is interesting to compare these facts with the figures for rheumatic recurrences, which are as follows: Arthritis 3, chorea 8, indefinite manifestations (myalgia and erythema nodosum) 2. The distribution of these recurrences among the children is shown in the following table.

Rheumatic Recurrences.	Class of Child.						
	P.	A.	B.	C.	D1.	D2.	Misc.
Acute arthritis ...	—	3	—	—	—	—	—
Chorea ...	—	5	3	—	—	—	—
Indefinite rheumatism ...	1	—	—	—	—	—	—
Erythema nodosum ...	—	1	—	—	—	—	—

It is worthy of note that 70 per cent. of the recurrences took place among Class A. In only one of these did a subsequent cardiac lesion occur, a result that can most probably be attributed to the thorough care and treatment accorded while in hospital.

During the second year of the clinic the fate of the same group of children was as follows: Died 2, disabled completely 1, developed cardiac signs 3, improved 1, and recovered 2. The changes in classification were as follows:

Improved.

Cases moved from Class D2 to B...	1
Cases " " Class C to A	1
Cases " " Class B to A	1

Worse.

Cases moved from Class P to B	1
Cases " " Class A to B	2

The incidence of rheumatic recurrence during this year was as follows: Arthritis 4 (1 acute, 3 subacute), chorea 10 (6 severe, 4 slight), chorea and arthritis 1, indefinite rheumatism 3. All these cases of acute arthritis were treated at home. The distribution of these recurrences according to the classification of the children is as follows:

Rheumatic Recurrences.	Class of Child.						
	P.	A.	B.	C.	D1.	D2.	Misc.
Acute arthritis ...	—	—	—	—	1	—	—
Subacute arthritis ...	1	—	2	—	—	—	—
Chorea ...	3	2	5	—	—	—	—
Chorea and arthritis ...	—	1	—	—	—	—	—
Indefinite rheumatism ...	1	2	—	—	—	—	—

A summary of the two years' work of the clinic is contained in the following table.

Class of Case.	Total.	First Year.		Second Year.		Improved.		Apparently Recovered.*	
		Died or Disabled.	Worse.	Died or Disabled.	Worse.	First Year.	Second Year.	First Year.	Second Year.
P. Rh.-Carditis ...	25	—	1	3	1	—	—	—	—
A. (Rh., old + Card.)-Card.	30	—	1	—	2	—	—	—	—
B. Rh.+Card.-Symps.	23	—	—	—	—	—	—	4	1
C. Rh.+Card.+Symps.	9	—	—	—	—	1	—	1	1
D1. Rh.+Card.+Symps.+ Disability	1	—	—	—	—	—	—	—	—
D2. Card.-Rh.+Symps.	2	—	1	—	1	—	1	—	—
Miscellaneous ...	2	—	—	—	—	—	—	—	—

In the first year 70 patients remained *in statu quo*, and in the second year 62.

* Since the work covers only two years, nothing final can be said as to this class of child.

With regard to the two fatal cases and the one child disabled during the second year, it should be recorded that in each instance hospital treatment had been prematurely terminated owing to ward infection, and that subsequent co-operation with the clinic had been most unsatisfactory. On the other hand, among those cases in which it was possible to carry out the full regime, no death has occurred, no permanent disablement, and no child has deteriorated to a point necessitating removal into Class C, while two children have been substantially improved and seven have recovered complete health.

CONCLUSIONS.

1. Any attempt to control the rheumatic infection in childhood must include provision for the acute, the convalescent, and the quiescent stages of the disease.

2. That by the establishment of a clinic of the kind described rheumatism in the children supervised can be

controlled, and the incidence of carditis reduced to a minimum.

3. That in it an instrument of research is provided for increasing our knowledge of the heart of the child and its responso to the rheumatic toxin, and that the correlation of records obtained in such clinics would throw very valuable light upon the nature of the disease.

4. Finally, that the cardiac classification proposed offers a suitable basis for such correlation.

It is a special pleasure to record our indebtedness to Miss Watson, almoner, for her invaluable assistance in the organization of the clinic, since the success of the department has been in a large measure due to her efforts. To Professor Leonard Findlay, to whose initiative the inauguration of the clinic was due, and under whose care it continues, I wish to express my sincere gratitude for his unfailing help and encouragement in the development and correlation of the work and the supervision of its details.

THE ACTION OF INTESTINAL EXTRACTS.

(Preliminary Communication.)

BY

W. E. DIXON, M.D., F.R.S.,

AND

J. H. WADIA, B.A., B.Sc.

(From the Pharmacological Laboratory, Cambridge.)

Cow and Dixon have shown that injections of boiled and filtered intestinal mucous membrane into dogs induce a secretion of pituitrin in the cerebro-spinal fluid. The effect is not immediate, and the pituitrin cannot be detected till about an hour after injection and does not reach its maximum for one and a half hours or more. The determination of the amount of pituitrin was made by the routine method on the uterus of the virgin guinea-pig. These observers also showed, however, that cerebro-spinal fluid so obtained exerts all the other known actions of pituitrin. The fact that the intestine is concerned in this secretion suggested to us that the pituitary secretion would likely be concerned with some digestive or metabolic mechanism. After numerous attempts to explain the secretion our efforts were at last led in the right direction by the observation of Burn that pituitary extract antagonizes the action of insulin.

If insulin is injected into anaesthetized dogs it produces a fall in blood sugar which reaches a minimum about three hours after injection. If in such an animal the cerebro-spinal fluid is tapped after the fashion of Dixon and Halliburton and tested for pituitrin it is found to be present one and a half to two hours after injection; that is to say, insulin increases the secretion of pituitrin just as it has been shown to increase adrenaline, but that this secretion is not obvious in the case of the pituitary until the blood sugar has been considerably reduced.

The following typical protocols will explain the nature of the experiments.

Experiment I.—Dog, male, weight 10.5 kilos. Anaesthetized by chloroform, then A.C.E., and finally morphine and urethane.

	Blood Sugar.	Pituitrin in C.S.F.
After 15 mins. anaesthesia ...	= 0.067	—
After 45 mins. " ...	= 0.074	—
After 1 hr. 15 mins. " ...	= 0.085	—
After 1 hr. 45 mins. " ...	= 0.095	—
After 2 hrs. 15 mins. " ...	= 1.040	—
After 2 hrs. 45 mins. " ...	= 1.150	—

Experiment II.—Dog, female, weight 12 kilos. Anaesthetized by chloroform, then A.C.E., and finally morphine and urethane. 24 units insulin were given intravenously fifteen minutes after anaesthesia.

	Blood Sugar.	Pituitrin in C.S.F.
Before injection and 14 mins. after anaesthesia ...	= 0.066	—
3/4 hr. after injection ...	= 0.061	—
1 1/2 hrs. " " " ...	= 0.055	—
2 1/2 hrs. " " " ...	= 0.047	++
3 hrs. " " " ...	= 0.043	++
3 1/2 hrs. " " " ...	= 0.051	—

Experiment III.—Dog, male, weight 10 kilos. Anaesthetized by chloroform, then A.C.E., and finally morphine and urethane. 20 c.cm. of boiled and filtered intestinal extract were given intravenously fifteen minutes after anaesthesia.

	Blood Sugar.	Pituitrin in C.S.F.
Before injection and 14 mins. after anaesthesia ...	= 0.074	—
3/4 hr. after injection ...	= 0.069	—
1 1/2 hrs. " " " ...	= 0.060	—
2 1/2 hrs. " " " ...	= 0.052	++
2 3/4 hrs. " " " ...	= 0.041	++
3 1/2 hrs. " " " ...	= 0.047	—

It will, of course, be suggested that the secretion of these two ductless glands is a provision for antagonizing excessive insulin action. The analogy between injections of intestinal extracts and those of insulin is so marked in this respect that we were induced to try the effect of alimentary extracts on blood sugar in rabbits. Injections of boiled and filtered duodenal mucosa in these animals induce a fall of blood sugar comparable with that of insulin. The fall often goes down to the convulsant level, though we have never been able to produce convulsions. The active substance is not secretin since it is destroyed by boiling with dilute acids, which process does not destroy the secretin, since we were able to show that the extract still contained a plentiful supply. Boiling with 1 per cent. sodium bicarbonate also destroys the blood sugar reducing substance. Boiled and filtered extracts of pancreas and many other tissues which we have used do not exert this effect. Ivy and Fisher state that the intestine contains one-fiftieth the amount of insulin of that in the pancreas. We have prepared insulin from the intestinal mucous membrane of pigs by the Dudley method; we are not prepared at the moment to give any figure of its amount, but it is considerably greater than that suggested by Ivy and Fisher. Nor at this stage are we prepared to offer information as to why this insulin body comes out in boiled intestinal extracts and not in other tissue extracts. We think, however, that the evidence suggests that pituitary secretion following the injection of intestinal extract is of the same nature as that which obtains after the injection of insulin.

A COMMENTARY

ON

TWO CASES OF HUNTINGTON'S CHOREA.

BY

ALAN F. GRIMBLY, M.A., M.D., D.P.M.,

DEPUTY MEDICAL SUPERINTENDENT,

AND

ISABEL G. H. WILSON, M.B., Ch.B., D.P.M.,

LATE ASSISTANT MEDICAL OFFICER,

SEVERALLS MENTAL HOSPITAL, COLCHESTER.

We have recently had under our care at Severalls Mental Hospital two brothers who suffered and died from Huntington's chorea. In view of the slight incidence of this disorder we venture to set forth in some detail an account of these cases based on our clinical and post-mortem investigations.

CASE I.

W. G., an ex-soldier, aged 34, was admitted to hospital on July 9th, 1917.

History.—The patient had served in the army for eleven years prior to 1914, and he re-enlisted during the war. He was appointed to the Field Artillery, and was stationed at Woolwich, but never saw active service abroad. A few months after re-enlistment he was sent to a military hospital for observation of his mental condition, and was found unfit for further service. He was discharged from the army and admitted to the local infirmary, being subsequently certified insane and sent to Cane Hill Mental Hospital, whence he was transferred to Severalls. He was stated to have contracted syphilis in India about 1906, and had been diagnosed as a case of dementia paralytica. A brother had died in Brentwood Mental Hospital.

Condition on Admission.—Mentally he was dull, apathetic, and took very little interest in his environment. He was rambling in his talk, and his memory was extremely defective; he could not remember his regimental number or the addresses of his near relatives. Speech was slurred. He was not hallucinated, but was restless, threatening, and inclined to be violent in his conduct. Physically he was well nourished, and showed no signs of injury. The cardiac, respiratory, and alimentary systems were normal. The pupils were equal, but sluggish in reaction to light. The knee-jerks were diminished and the gait was ataxic. He was

considered to be suffering from general paralysis of the insane. There is no record at this time of the existence of choreiform movements.

Progress.—Shortly after his admission definite choreic movements became manifest. They rapidly developed into constant, generalized, jerky movements of the head, neck, and limbs, which were invariably accentuated when the patient was addressed. Examination of the cerebro-spinal fluid was negative for syphilis, and the diagnosis, being altered to Huntington's chorea, was confirmed when a brother was admitted in June, 1918, obviously suffering from this disorder. Thenceforth a progressive dementia supervened. The patient became slovenly and defective in his habits, very amnesic, always irritable, occasionally hostile, and more and more restless and resistive to attention. He became increasingly feeble, and died on January 7th, 1925, the choreic movements persisting until the end.

Post-mortem Examination.

(a) **Macroscopic.**—**Brain:** Dura mater normal. Marked thickening of the pia-arachnoid, with a few scattered milk-white patches. Excess of subarachnoid and ventricular fluid. Local flattening and atrophy in frontal and fronto-parietal areas. No macroscopic lesion of basal ganglia. Cerebellar consistency soft in general. **Thorax:** Thyroid fibrotic. Old adhesions of right pleura. Some old fibrosis of right lung. Heart normal. **Abdomen:** Gall bladder full of small faceted stones. Nothing else abnormal.

(b) **Microscopic.**—Nothing abnormal was noted in the microscopic appearance of the suprarenal glands or liver. Sections were taken from the medulla, pons, cerebellum, and mid-brain; also from the caudate and lentiform nuclei, thalamus, and precentral gyrus. These were stained with haematoxylin and eosin by Nissl's method, and by Levaditi's silver nitrate. The following were the changes seen:

(1) **Leptomenigitis.**—This consisted more in thickening of the pia-arachnoid than in increased vascularity.

(2) **Small Round-celled Infiltration in the Perivascular Lymphatics.**—This was not seen in the medulla, pons, or cerebellum, but became noticeable in the mid-brain, being more marked towards the margins of the transverse section. The infiltration was more definite in the lentiform nucleus, thalamus, and precentral gyrus, and was seen most clearly in the caudate nucleus. Not the larger vessels, but the capillary vessels were affected, and of these less than half showed the infiltration. The cells were frequently arranged in a single line beside the vessel. Occasionally there were groups of cells in the Virchow-Robin spaces, but the condition could hardly be said to amount to the "cuffing" of acute encephalitis.

(3) **Infiltration of Small Round Cells in the Pericellular Lymphatics.**—One or two small cells in the pericellular space were not taken as abnormal. Here and there, however, were found nerve cells round which were clumped three, four, or more small cells. In most sections these were only to be found by searching carefully; they were most plentiful in the precentral gyrus.

(4) **Dilatation of Vessels.**—Increased vascularity, with dilated and congested vessels, was only seen in one group of sections taken of the thalamus. Here the first glance gave the impression of encephalitis, and indeed one small haemorrhage was found, but there were only a few round cells in the lymphatics.

(5) **Cell Degeneration.**—The cells in most sections appeared healthy, including those of the substantia nigra. In the lentiform nucleus and the precentral gyrus were cells in all stages of degeneration, but the great majority of the cells seemed healthy. The degeneration was quite irregular in distribution.

Summary of Pathological Findings.

(a) In the cerebellum, pons, and medulla: no change except leptomenigitis.

(b) In the mid-brain, caudate and lentiform nuclei, thalamus, and precentral gyrus: infiltration of small round cells, most marked in the caudate nucleus.

(c) In the thalamus: increased vascularity in addition.

(d) In the lentiform nucleus and precentral gyrus: some degeneration of nerve cells.

CASE II.

G. G., a man of no occupation, aged 43, was admitted to hospital on January 17th, 1918.

Previous History.—The patient had not been previously under care and treatment, but he was stated to have spent "three parts of his life in the workhouse," where he used to be employed in the bootmaker's shop. During the last two months he had been restless and violent in his conduct, and had assaulted various people without provocation. He had been habitually insulting to members of the opposite sex, degraded in his habits, and "lay about in the fields rough at night."

Family History.—One brother died at Brentwood Mental Hospital. One brother was living at Severalls Mental Hospital. The mother was insane. The father "does not suffer from any disease of a choreiform nature, but has malignant disease of the oesophagus."

Condition on Admission.—Mentally he was confused in thought, and could give little account of himself. He was restless, excited, and resistive to attention. He had delusions of a persecutory nature regarding women, stating that females followed him about and received money for ill-treating him. He had a marked inferiority complex. Physically he was fairly nourished, and the heart, lungs, and alimentary system betrayed little abnormality. The knee-jerks were exaggerated, and he showed definite and constant choreic movements of the muscles of the limbs and face. The gait was very unsteady. The pupils were equal and normal in reaction to light and accommodation. Articulation was much impaired, and he was defective in his habits.

Progress.—The patient showed a rapidly advancing mental deterioration. He was always irritable and hostile in his attitude

to his environment. His speech soon became so affected that his remarks were altogether unintelligible. Constant and violent choreic movements of the head and neck and limbs persisted, resulting frequently in bruises and abrasions, in spite of elaborate padding of his immediate environment and the adoption of all possible precautions against injury. He became gradually enfeebled, and died on December 26th, 1921.

Post-mortem Examination.

Brain.—Skull-cap thickened. Generalized congestion of the superficial cerebral blood vessels. Oedematous condition of the pia-arachnoid. Excess of ventricular and subarachnoid fluid. Local atrophy of frontal and fronto-parietal areas. Generalized cerebral softening. Brain stem and cerebellum soft in consistency.

Thorax.—Old adhesions at apices of both lungs and congestion at bases. A few small patches of atheroma in the aorta. Heart showed nothing abnormal.

Abdomen.—The gall bladder was distended, and contained two gall stones.

A microscopic examination was not performed at the time of the patient's death.

The following points appear to be of interest in connexion with the cases described.

1. The existence of a family history of insanity transmitted through the mother, three sons becoming insane, and two of these developing Huntington's chorea.

2. The difference in the early history of the two brothers subsequently affected with chorea. One (G. G.) had never been capable of regular employment; the other (W. G.) had a long record of army service prior to and during the first half of the war.

3. The younger brother (W. G.) had a history of syphilis contracted abroad during military service in 1906, and was diagnosed on admission as a case of general paralysis of the insane.

4. The same brother exhibited no choreic movements at the time of his admission; whereas G. G. showed unmistakable evidence of chorea from the first.

5. Regarding the difference in the age factor, the younger brother, who had led an active life, developed the disease at 34, while the older, who had spent the major part of his existence under institutional control, exhibited no symptoms until he was 43.

6. As regards the morbid anatomy, both cases exhibited thickening of the pia-arachnoid, local atrophy in the frontal and fronto-parietal areas, generalized cerebral and cerebellar softening, and a pronounced increase of cerebro-spinal fluid with dilatation of the ventricles.

7. In relation to the case (W. G.) in which it was possible to carry out a detailed examination under the microscope, the pathological changes consisted of chronic leptomenigitis, small round-celled infiltration of the perivascular lymphatics, particularly definite in the caudate nucleus, increased vascularity in the thalamus, but without any definite focus of acute encephalitis. There was also some degeneration of pyramidal cells, especially in the precentral gyrus.

The rarity of Huntington's chorea has prompted us to record the facts at our disposal relating to the two brothers who suffered, and ultimately died, from this disorder at this institution.

In conclusion, we wish to express our indebtedness to Dr. R. C. Turnbull, medical superintendent of Severalls Mental Hospital, for permission to publish this account.

THE INFLUENCE OF THE VERMIFORM APPENDIX ON GYNAECOLOGICAL SURGERY.*

BY

R. S. STATHAM, O.B.E., M.D., CH.M.,

HONORARY GYNAECOLOGIST, ROYAL INFIRMARY, BRISTOL; CLINICAL LECTURER AND DEMONSTRATOR OF OBSTETRICS IN THE UNIVERSITY OF BRISTOL.

The figures upon which this paper is based are taken from a series of abdominal sections performed in the gynaecological department of the Bristol Royal Infirmary. They have not been selected in any way, and include every laparotomy done in the department during a period of twelve months. The total number is 300, and I am indebted to the late Professor W. C. Swayne for permission to use cases upon which he had operated, and

* Based on a paper read before the Bristol Medico-Chirurgical Society.

which amount to a little over one-quarter of the total. In almost all of his cases I was present at the operations and able to examine the material removed.

The operations can be roughly classified as follows:

Operations.	No.	Appendix Removed.	State of Appendix.		
			Acute.	Chronic.	Slight.
Hysterectomy for fibroids ...	48	10	2	6	2
Myomectomy	7	0	—	—	—
Myomectomy (during pregnancy)	5	1	—	1	—
Ovariectomy	54	3	—	2	1
Oöphorectomy	34	15	1	9	5
Hysterectomy for other causes	9	2	2	—	—
Wertheim's panhysterectomy...	8	0	—	—	—
Ectopic pregnancy	17	2	—	2	—
Adherent retroversion	31	11	1	9	1
Pyosalpinx	70	39	12	21	6
Hydrosalpinx	3	1	—	1	—
Appendicitis (2 plus pregnancy)	6	6	4	2	—
Unclassified	8	1	1	—	—
			23	53	15
Total	300	91	91		

This classification was used merely to show the type of operation performed and its association with disease of the appendix. It will be seen that the appendix was removed 91 times in 300 cases, and its condition is stated opposite each group of operation cases.

I have classified the condition of the appendix into three groups, as follows:

Acute.—Includes those cases with definite perforation or abscess formation. All cases with obvious acute inflammation.

Chronic.—Includes cases which had previously suffered from a well marked appendicular inflammation with definite adhesions, kinks, etc.

Slight.—Implies definite changes and adhesions (apart from anatomical ones) but not so well marked as to make it certain that the appendix, *per se*, was sufficiently diseased to cause the pain or other symptoms complained of.

No doubtful cases were included in this list, the appendices being sent to the pathologist for report for section in those cases where its naked-eye appearance was indefinite. Eight cases in which the appendix was removed "just because it was there" have not been included.

It will be seen that these operations fall roughly into two groups: (A) Operations done for inflammatory pelvic conditions; and (B) those in which operation was done for fibroids, ovarian conditions, and carcinoma. Group B contains 131 cases and the appendix was removed 31 times (23.6 per cent.).

The other cases were all caused by or gave rise to inflammatory reactions and can be grouped under that convenient term "pelvic peritonitis." The total was 169. In this group the appendix was removed on 60 occasions (35.5 per cent.).

I have included in Group B oöphorectomies, because it is not usual at the Bristol Royal Infirmary to remove the ovary unless it is badly adherent, prolapsed, or totally degenerated. I myself do not think that a large ovary gives any symptoms unless complicated by a pelvic peritonitis and adhesions.

In the non-inflammatory group of operations (Group A) there were two cases of special interest which occurred within a few weeks of each other. The patients were both young women under 27; both had been apparently quite healthy, including their menstrual histories. Each of them was suddenly taken ill—one with diarrhoea and vomiting after a picnic, the other with acute retention of urine.

In the first case there was a large single cervical fibroid completely filling the pelvis, which I removed by total hysterectomy, after preliminary myomectomy. The caecum contained a lump

the size of a Tangerine orange, situated at the base of the appendix; this was excised altogether with the greater part of the caecum, and was reported by the pathologist, Dr. Kay-Mount, as "typical so-called spheroidal cell carcinoma of the appendix." She did very well for eighteen months and was then readmitted to the infirmary with a large mass in the right iliac fossa. My surgical colleague, Mr. C. F. Walters, kindly saw her with me and we both considered it to be a recurrence. He operated and removed the remains of the caecum, the ascending colon, and the greater part of the transverse colon. Very much to our surprise the pathological report stated that this was a chronic inflammatory condition and showed no evidence of malignant disease. She is at present in perfect health.

The second patient developed acute retention and was found to have a large fibroid filling up the pelvis (weighing 9 lb. on removal). This was removed by subtotal hysterectomy. On examining the caecum a growth the size of a walnut was found on the distal end of the appendix. This was removed with the greater part of the caecum, and she appears to have made a complete recovery. The pathological report stated that this was also "spheroidal cell carcinoma."

Among the other cases in Group A the appendix was found to be densely adherent—twice to an ovarian cyst and four times to a fibroid.

In the much larger and more important group of operations for conditions involving peritonitis the first question which impressed itself on me was whether the inflamed appendix was the cause or the result of the condition found at operation. I found this almost impossible to decide in the majority of cases, the history being of little use except where there had been a recent attack of puerperal sepsis or gonorrhoea. The only criteria I could adopt were (1) that infection of both tubes probably implies an ascending infection; (2) recent gonorrhoea and puerperal sepsis are of similar significance; (3) a right-sided salpingitis, associated with appendicitis, and in which the left tube appears to be normal, is probably appendicular in origin.

There were 16 cases in Group B in which I feel fairly certain that the appendix was the original cause of the condition. In 8 of these the appendix and tube were continuous, with the fimbriae of the tube enveloping the end of the appendix, and in 2 there was pus and a faecal concretions actually in the lumen of the tube itself.

Since this series of cases was completed I have operated upon 5 cases from whom the appendix had been previously removed for acute appendicitis and who had had a normal gynaecological history up to the onset of the acute attack of appendicitis, but since that time had suffered from dysmenorrhoea, etc. In all these cases there was extensive chronic pelvic peritonitis with involvement of the right tube and ovary.

Operations for Pyosalpinx.—It will be seen that 39 out of the 70 cases showed definite appendicular disease (that is, 55.7 per cent.), and that in 12 cases it was acutely inflamed. It seems likely that in at least half the cases of pyosalpinx the appendix will be more or less acutely infected, and will probably need surgical intervention sooner or later, if, indeed, it is not the primary cause of the condition.

Adherent Retroversion.—These cases I have classed together, the great majority of them being treated by Gilliam's operation on the round ligaments. In all these cases there was more or less old peritonitis with adhesions in Douglas's pouch and matting of the tubes and ovaries. Here again the appendix was found to be affected in 31 per cent. of the cases, but, as might be expected, it was of the chronic type, except in one case, where I think a recent attack had supervened on an old chronic condition.

Oöphorectomy.—Here a similar condition prevails; 44 per cent. of the cases showing affection of the appendix; in these cases I am inclined to think that the appendix was usually the causal agent, and that the pain and malaise were due to the chronic appendicitis, and not to the enlargement of the ovary, although in all cases in which the ovary was removed there was considerable destruction of the ovarian tissue, consequent on prolonged inflammation and adhesions.

Ectopic Pregnancy.—Two very interesting cases were met with. (1) A case of tubo-abdominal pregnancy with a large gestation sac, in Douglas's pouch, containing twin four-months embryos, the caecum forming the outer boundary of the sac, the appendix being densely incorporated in its wall, and much thickened and reddened. It

was removed with the sac and the patient did well. (2) The other patient had a large right-sided tubal gestation with a very long appendix lying across and adherent to it; the appendix was gangrenous and a large concretion was just bursting through its tip. The gestation sac was full of thin, foul-smelling fluid; no embryo was found, but there was an abundance of necrosing chorionic tissue.

Hysterectomy for other Causes.—Most of the cases were for acute puerperal peritonitis; here the appendix was four times removed, twice being acutely inflamed. In both cases I feel certain that it was the cause of infection.

Appendicitis.—There were two cases, in the series, of appendicular abscesses complicating pregnancy at the seventh and eighth month. Four were found when operating for "cystic ovary." The ovaries were left, and the patients' symptoms have been cured completely by the removal of the appendix.

Deaths.

I have not found any reason to think that the removal of the appendix in any of these cases has been prejudicial to recovery or convalescence. There have been eleven deaths among the 300 cases—as follows:

Fibroids	2
1 from cardiac failure—aortic regurgitation.					
1 from pulmonary embolism.					
Ovarian	1
Malignant.					
Other hysterectomies	4
3 from puerperal peritonitis					
1 from criminal abortion, with perforated uterus and gas gangrene.					
Wertheim's hysterectomy	1
From shock.					
Pyosalpinx	2
1 from shock.					
1 from peritonitis.					
Myomectomy and pregnancy	1
Miscarriage and pulmonary embolism nine days after operation.					

In only one of these cases was the appendix removed; the patient had pyosalpinx, and died of peritonitis from which the gonococcus was recovered, so that I do not think that the mortality rate has been in any way affected by the removal of the appendix.

Among the oophorectomies two cases became infected in the abdominal incision, and possibly the appendicectomy was the cause of this occurring; otherwise the removal of the appendix seems to have caused no risk to the patient and has only occupied a few minutes. In 23 cases out of the 300 the appendix was acutely inflamed and would have required removal in any case.

I have found it very difficult to obtain any definite information as to the position of the appendix in health, but it appears that most of the authorities consider that the appendix may be below the brim of the pelvis in about 50 per cent. of cases, and also that in a large number of cases there is a definite anastomosis between the branches of the ovarian and appendicular arteries.

Conclusions.

1. The appendix is very likely to be affected by pelvic inflammations and may be the cause of salpingo-oophoritis and its consequences more frequently than is expected.

2. The appendix should be suspected and examined in all cases of pelvic peritonitis, and it should be removed if it is in any way diseased, to prevent further trouble at a later date.

3. Even when the operation is performed for a condition which is not inflammatory the appendix should be examined; 20 per cent. of my series show definite disease of this organ, and 2 of the 31 appendices removed were reported as malignant.

4. Acute pyosalpinx is frequently complicated by acute appendicitis and vice versa.

5. "Oophoritis" as a disease, and apart from pelvic peritonitis, should not be diagnosed. If at operation the ovaries are found to be merely enlarged and not adherent, then the appendix is most likely to be the cause of the

patient's pelvic pain. In corroboration of this, the number of oophorectomies performed at the Royal Infirmary has fallen to a quarter of the number which were done before the war, and the results as to the cure of chronic pain have very greatly improved.

6. I would advance with great diffidence that it is just as well to remove a pelvic appendix whenever found, even if it appears quite healthy to the eye.

In conclusion, I wish to express my gratitude to Drs. Kay-Mount, Fraser, and Todd for cutting numerous sections of appendices and tubes in the pathological department of the Royal Infirmary.

THE RADICAL TREATMENT OF TRIGEMINAL NEURALGIA

AS EXHIBITED IN SEVENTEEN CONSECUTIVE CASES.

BY

BASIL HUGHES, D.S.O., M.A., M.B., B.Ch.CANTAB.,
B.Sc.LOND., F.R.C.S.ENG.,

SURGEON, BRADFORD MUNICIPAL GENERAL HOSPITAL; HONORARY SURGEON,
BRADFORD CHILDREN'S HOSPITAL; HONORARY ASSISTANT
SURGEON, BRADFORD ROYAL INFIRMARY.

SOME ANATOMICAL CONSIDERATIONS.

The fifth cranial nerve is a fairly typical dorsal nerve. What is the corresponding ventral nerve, and, still more important, what is its portion in the sympathetic chain? There are at least four ganglia, sympathetic in structure, connected with this nerve—namely, Meckel's, Arnold's, the ciliary, and the submaxillary. They receive their efferent fibres from the third and seventh cranial nerves, which must therefore be regarded as the ventral element, while their afferent fibres are supplied indirectly from the superior cervical ganglion. It is of importance to note that the cell stations of the sympathetic nerves are within these ganglia, and not in the ganglion of the dorsal root (the Gasserian ganglion) or the cord.

PATHOLOGY.

Our present knowledge of the pathology of tic-douloureux is both unsatisfactory and unreliable. Degenerative changes of a doubtful kind and a round-celled infiltration have both been described as occurring in the Gasserian ganglion. Pressure on the ganglion by tumours can, according to some observers, give rise to a "true" tic (a very doubtful proposition). In sections of the ganglion removed at operation I have not been able to confirm any of these findings, not even in the minutest degree. My own most constant finding is a hypertrophic obliteration of the arteries of the ganglion itself due to hypertrophy of the circular muscular coat. It is not a condition of endarteritis. The change is identical with that seen in the arteries of the feet in that particular type of Raynaud's disease associated with intense pain of an unbearable kind in which patients readily submit to amputation in order to obtain relief. Similar changes were seen in the arteries of men who suffered with trench feet and the accompanying erythromalgia.

This is the only change I have been able to find in the Gasserian ganglia of patients suffering from true tic, and it is of important significance. It suggests arterio-spasm, arterial cramp, a condition allied to angina which might suitably be called "arterial angina." It is an angioneurosis, brought about by some sympathetic unbalance.

If this be correct, afferent painful impulses from the arteries will travel by way of the ganglia mentioned, passing thence via the posterior nerve roots to the brain. This view is strengthened by the fact that removal of Meckel's ganglion gives complete relief in instances of tic affecting the middle division of the trigeminal. Interesting in this connexion are certain methods of treatment, hitherto empiric, such as removal of the superior cervical ganglion, ligation of the carotid arteries, which in this connexion is similar to removing the superior cervical ganglion, the exhibition of iodides and belladonna, and the use of amyl nitrite for relieving the spasm when at its worst.

SYMPTOMS.

The disease manifests itself at first in short lightning attacks of pain which start at some definite point, usually in the upper lip, or in one or more teeth of the upper jaw. The pain tends to spread from the starting-point and involves other areas. Starting in one or more teeth of the upper jaw, it spreads backwards and thence into the third division, lastly affecting the eye. On the other hand, but more rarely, the attacks may originate in and remain confined to the first division. The intervals between the attacks are at first considerable—weeks or even months. As the condition progresses the intervals between the attacks become shorter, and the spasms both longer in duration and more severe in character. At first the trouble is thought to lie in the teeth, and usually they have been extracted.

When the condition becomes fully established the attacks are very typical. A glass of cold water, a cup of tea, or even going out of doors, is quite sufficient to excite a paroxysm. The patient holds his head in both hands; lightning pains, causing indescribable agony, prevent him from moaning or uttering a cry; the facial muscles twitch, specially those of the eye; the lacrymal and salivary glands secrete, the pupil on the affected side dilates; following the spasm the face flushes on the side affected, and unilateral sweating occurs. Repeated attacks rapidly reduce the patient to a complete wreck, and unless relieved sufferers will themselves seek relief in self-destruction.

The pain is obviously not a neuralgia or a neuritis; it is a cramp, an arterial angina the result of arterio-spasm. It is due to some uncontrolled activity of the vasomotor nerves. The more I see of the condition the more convinced I am that this is the case.

TREATMENT.

Treatment lies between alcohol injections into the nerve or its ganglion and radical operative treatment. Alcohol injections may give permanent or temporary relief—most often the latter, the recurrences being worse than the original attacks. Twelve of my cases had alcohol injections before coming to me, and of these four were unable to open their mouths to the full extent owing to fibrosis of the masseter and pterygoid muscles following the injections.

Surgically several operations have been practised, but I have confined myself to the following three: (1) division of the sensory root; (2) division of the second and third divisions; (3) division of the second and third divisions with removal of the outer third of the ganglion. I do not think it matters whether the sensory root is divided or whether the second and third divisions are divided. The important point is to divide the nerves proximal to Meckel's, the otic, and submaxillary ganglia.

In my experience division of the sensory root is the easiest of the three operations. I performed this operation in five of my cases, and in every instance troublesome eye symptoms occurred; consequently I have abandoned it (Frazier-Spiller operation). I performed Hutchinson's operation (3) in four cases, and in my opinion this is the most difficult operation, as haemorrhage is apt to occur however careful and patient one may be. I performed a modification of Abbe's operation (2) in eight cases, twisting the proximal ends of the divided divisions and pushing the distal ends through the oval and rotund foramina, finally plugging the foramina with cotton-wool. In operations (1) and (2) there have been no eye symptoms and relief has been permanent.

It is only fair to state that any of these operations are difficult, and each surgeon will be guided by what he finds in his hands is the most expedient method. They are operations not to be undertaken lightly, and not before several attempts have been made upon the cadaver. I use an incision starting just behind the pinna, curving upwards in semicircular fashion to end at the mid-point of and just below the zygoma. The flap is turned down, and with it the posterior half of the zygoma as far as the infra-temporal crest. The pin of the trephine is placed just above and in front of the triradiate process of the zygoma, and a circle of bone is removed. This done, the dura is detached to the extent of three-quarters of an inch around

the opening, which is enlarged inferiorly as far as the infra-temporal crest and no further; otherwise the pterygoid plexus of veins may be injured and troublesome haemorrhage will make clear work impossible. I now detach the dura from the base of the skull with the gloved finger until an obstruction is reached. This obstruction is the third division. Reference to a skull will make this plain. The bent handle of a dessert-spoon is now introduced as a retractor to elevate the brain, and strips of gauze soaked in hydrogen peroxide are packed in between the handle of the spoon and the base of the skull. These are left in for from three to five minutes. This renders the field wonderfully clear, and arrests what little oozing there is from the bone. The second and third divisions are readily identified when the gauze strips are removed with the middle meningeal artery, whose relation to the roots is inconstant. Any of the three operations can now be completed. If the sensory root is to be divided the middle meningeal artery is divided after plugging the foramen spinosum with a small plug of cotton-wool. The dura is divided along a white line which marks the line of fusion of the dura propria around the third division. The ganglion is thus exposed and traced backwards to the sensory root. This is then divided, sparing if possible the motor element lying beneath it.

If the second and third divisions only are to be divided they are seized with forceps and slowly twisted proximally after division, the distal ends being pushed through their respective foramina, which are afterwards plugged with cotton-wool. In my opinion this is the operation of choice, as there have been no recurrences after four and five years, which rather supports the theory that the condition is sympathetic in origin, and that the afferent cell stations are situated in the sympathetic ganglia. An attempt should be made to save the motor element of the third division. I have been able to do this in four of my cases, but in those in which it was apparently divided the inconvenience has proved slight.

The post-operative phenomena of interest are as follows:

(1) Eye changes which manifest themselves in trophic conditions of the cornea. In one instance a conical cornea resulted with visionary disturbances.

(2) Paraesthesias in the form of pins and needles travelling over the areas of the divided nerves—sometimes pain in the form of tic, but less severe and less frequent—curious sensations in the pharynx (pterygo-palatine nerve), a feeling of fullness in the ear on the same side (tympanic branch of the auriculo-temporal nerve).

(3) Anaesthesia in part of the palate, tongue, and nose, resulting in the unconscious swallowing of foreign bodies—for example, plum stones.

(4) Some paralysis of the palate on the same side which may rather interfere with speech (tensor palati via the otic ganglion).

(5) Paralysis of the muscles of mastication with withering of the temporal muscle, and the consequent disfigurement if the motor root is wholly divided.

(6) Temporary mental symptoms.

It is of interest that post-operative infection of the respiratory annexes and trophic changes in the mucosa have been conspicuous by their absence.

Of seventeen cases operated upon four were male and thirteen female—that is, 75 per cent. female. There were two deaths—one a woman, aged 75, with advanced aortic disease; the other a woman, aged 65, whose general condition was exceedingly poor. This gives a mortality in this series of 11.8 per cent. With some diffidence I connect their deaths with the operation, but it will, I hope, prove that the cases were in no way picked.

In competent hands and in suitable cases I think that to-day this operation can be undertaken in perfect safety; in not one of my cases has there been recurrence. The first case was operated upon six years ago; in one instance there were symptoms on the opposite side, which subsided. In view of what has been said in the text the radical cure is correct both scientifically and practically, and is undoubtedly preferable to alcohol injection, which is but palliative and temporary.

CARCINOMA AFTER GASTRO-ENTEROSTOMY.

BY

DAVID R. OWEN, B.A. CANTAB., F.R.C.S. ED.,

HONORARY ASSISTANT SURGEON, SOUTHPORT INFIRMARY; SURGICAL ASSISTANT AND REGISTRAR, DAVID LEWIS NORTHERN HOSPITAL, LIVERPOOL.

THE recent note by Sir George Beatson¹ suggests that the following case is worthy of record. It is of interest in several ways. It demonstrates the importance of a thorough examination of patients claiming compensation for a comparatively trivial accident. It shows the possibility of a simple, unsuspected tumour (chondroma) causing symptoms fitting in with the history of an accident. Finally, the case is recorded as one showing a carcinoma, following a gastro-enterostomy for ulcer, in which all the evidence appears to be against the theory that the ulcer, or ulceration around the gastro-enterostomy, was the cause of the carcinoma.

The patient went to Mr. G. C. E. Simpson, owing to the legal aspect of the case, complaining of pain in the region of the lower ribs on the left side, and stating that through an accident at work, some ten months previously, he had fractured the tenth and eleventh ribs. Two months after the accident he went back to his work, but was unable to do it owing to the pain, which he referred to the site of the fractures. He had not worked since.

While examining the patient a swelling was felt in the epigastrium and he was admitted to hospital for full investigation. Here he admitted that recently he had also suffered from some epigastric fullness about half an hour after food, which gradually passed off in an hour or so. His appetite was good and there was no vomiting, but a slight loss of weight was admitted. He further stated that he was operated upon ten years before for "stomach trouble" at the Royal Infirmary. Professor R. E. Kelly very kindly confirmed that he had performed a gastro-enterostomy upon the man for pyloric stenosis in 1915, the patient then being 43 years of age.

Examination revealed some tenderness of the tenth and eleventh ribs in the mid-axillary line. In the epigastrium and extending to the left a firm, rounded, and slightly tender tumour, which moved with respiration, was palpable. It was dull to percussion, but the dullness was not continuous with that of the liver, which appeared to be normal. A fractional test meal showed no free hydrochloric acid and a very low total acidity; x-ray examination showed a small gastro-enterostomy opening and a very irregular pyloric antrum, and suggested carcinoma ventriculi.

At operation an advanced carcinoma of the pyloric part of the stomach was found. The old gastro-enterostomy stoma was almost closed, and masses of glands were seen in the lesser omentum and constituted part of the mass felt at the clinical examination. The pancreas was surrounded by hard, enlarged glands, but was not itself involved. Anterior gastro-enterostomy was rapidly performed, and through the stomach opening the margin of the growth could be felt reaching just up to the old stoma, but not surrounding it. The patient did well for two days, and then suddenly collapsed, after vomiting once only on the third day, and died.

Several medical men witnessed the autopsy owing to the possibility of a legal action under the Workmen's Compensation Acts. There was definite angling of the tenth costo-cartilaginous junction on both sides, but more marked on the left; it was agreed by all that this could not have had any connexion with the development of the carcinoma. No other origin of the carcinoma was found than the pyloric antrum and pylorus. An old healed gastric ulcer scar was found immediately proximal to the growth on the lesser curve. The old stoma was free from growth except at its distal margin, where it was becoming involved as the tumour spread upwards along the stomach wall. Hard, enlarged glands were present right up to the mediastinum. There was some duodenal ileus. The other organs were normal except that a small innocent chondroma was found in the left pleural cavity opposite the middle of the tenth rib. It was picked off the parietal pleura quite easily, and its nature was confirmed later by microscopical section. Sections of the growth in the stomach showed it to be an adenocarcinoma of the colloid type. By section metastases were proved to be present in all the glands cut, right up to the highest part of the mediastinum.

From a forensic point of view this case shows the wisdom of a systematic examination, even when the patient complains of nothing more than tenderness over the seat of an old fracture. It is possible that, although the chief trouble was cancer, some of the symptoms may have been due to pressure by the chondroma on the intercostal nerves during inspiration.

From the clinical point of view it is more than doubtful if the ulcer had any relation to the carcinoma, as, with Mr. Sherren,² we feel that, after a period of excellent health for ten years following a posterior gastro-enterostomy for simple ulcer, ulcer-cancer must be rare. The long period of health suggests that the ulcer was simple

and cured; the short recent history of dyspepsia in itself suggests a carcinoma ventriculi not related to ulcer in its etiology.

The pathological evidence also supported this opinion. The growth involved the pyloric antrum distal to an old ulcer scar almost entirely. It extended up to the gastro-enterostomy but did not surround it, only reaching its distal margin. The sections did not in any way suggest a previous ulcer in the malignant tissue, and showed none of the scirrhus type of carcinoma so usual in the ulcer-cancer.^{3 4}

Most cases of carcinoma following ulcer or gastro-enterostomy have been described with a view to showing that the malignant condition has arisen in or from the simple. In this case all the evidence appears to be against this theory; but, while the gastro-enterostomy did not appear to be the seat of malignancy, its physiological effect upon the mucosa of the pyloric antrum and its secretion needs consideration. The pyloric mucosa, after gastro-enterostomy, may have been bathed in a fluid deficient in acid rather than in an hyperacid gastric juice. Just as hyperacidity is frequently associated with ulcer, so is hypoauidity with malignant disease. More evidence may thus be deduced that hypoauidity is one of the contributing causes of carcinoma ventriculi rather than the result of the disease.

Another factor for consideration is the likely presence of adhesions following gastric ulceration. These will tend to limit the mobility of the pyloric antrum, and with an efficient gastro-enterostomy this part of the stomach might be expected to secure a very considerable amount of rest and freedom from irritation, and be less likely to develop malignant changes; but the post-operative hypoauidity would still be present. A large number of surgeons seem to regard gastro-enterostomy as successful in many cases of gastric ulcer, even though in most cases partial gastrectomy by the Polya method or one of its modifications would appear to be the ideal treatment owing to the slight amount of shock in comparison with the extent of the operation.⁵ It may be mentioned here that one of Mr. Simpson's cases, a sleep-walker, got up on the night after operation. He was none the worse, and so was allowed up daily for a short time from the fourth day. He did so well that we are considering allowing a similar procedure in partial gastrectomy cases in future, or at all events commencing to move them considerably earlier than in the past.

In conclusion, in the case here described all the evidence, with the possible exception of the physiological effect of the gastro-enterostomy, is in favour of the carcinoma ventriculi having arisen without any relation to previous ulceration of the stomach or gastro-enterostomy stoma.

I wish to thank Mr. Simpson for allowing me to publish this case and for the help he has given me.

FATAL HAEMORRHAGE FROM THE LIVER IN AN INFANT FIVE DAYS OLD.

BY

J. ALLAN BERRY, M.S.,

MEDICAL SUPERINTENDENT, NAPIER HOSPITAL, NEW ZEALAND.

THE following account of a rather unusual case seems worthy of record.

A male child was born at McHardy Home at 2 a.m. on August 25th, 1924; it weighed 10 lb. The mother, aged 42 years, had had nine previous children, all weighing between 9 and 10 lb. at birth. They were all alive and in good health. The mother appeared to be perfectly healthy, and gave a negative Wassermann reaction. Labour in the present case was normal and easy, and up till the fifth day the child's condition was perfectly satisfactory. It had lost about 10 oz. in weight, and was entirely breast-fed. On the fifth day the child was taken to its mother at 11 a.m., took its feed well, and was brought back to the nursery at 11.30. At 12.15 p.m. it was crying for a time, but nothing abnormal was noted. At 1.45 p.m. it was sleeping and looked well. At 2.15 p.m. it was noticed to be very pale and to be crying feebly. The sister in charge informed me that the child looked as if it had had a severe haemorrhage. On examination

the abdomen was noticed to be rather distended, and an area of dullness was found in the right flank continuous with the liver dullness. No tumour could be palpated. A diagnosis of haemorrhage into the peritoneum was made, possibly from some abdominal tumour. At 3.30 p.m. the child died.

Post-mortem Examination.—This was performed about 9 p.m. on the same day. The thoracic viscera appeared normal, but there was very little blood in the heart or great vessels. Through the right dome of the diaphragm a dark mass could be seen. On opening the abdomen about 6 oz. of free blood and blood clot were found, mostly in the right flank. The right lobe of the liver was dark from blood effused under the capsule, which was stripped up over an area extending above into the diaphragmatic surface of the liver, and in front to within about three-quarters of an inch of the falciform ligament. From a minute perforation on the anterior aspect of the capsule blood was still oozing. On cutting across this area a deep sulcus was seen on the anterior surface, running from above downwards and slightly inwards, about 2½ inches in length. To the right of this a dark area, roughly ovoid, sharply demarcated from the liver, was made out. This area was situated in the right lobe, and extended into the distal surface in front, and slightly on to the abdominal aspect beneath. It measured about 1½ inches across and about 2½ inches from above downwards. The liver weighed 243.06 grams. The remaining organs appeared normal.

Microscopical Examination of the Liver.—There was congestion and marked fatty change. An area of haemorrhage showed intermingled strands of fibrous tissue and a boundary of compressed haemorrhagic and fibroid liver tissue. This boundary showed in parts a leucocytic infiltration, and throughout the haemorrhagic area the leucocytes appeared to be increased, and were for the most part mononuclear in type. There was some early organization of the blood clot which would correspond with the period—five days—between the birth and death of the infant. The appearances suggested that the haemorrhage occurred at birth from trauma.

There can be very little doubt that the fissure found in the liver was a laceration which probably occurred during birth, although the fact of labour having been easy and normal makes it rather difficult to understand how it occurred. Holt states that small haemorrhages are not uncommon upon the surface of any of the viscera covered by peritoneum, and that intraperitoneal haemorrhages are rare, but may be very extensive, amounting to six or eight ounces, as in the present instance. Small surface haemorrhages of the liver, he states, are not infrequent. Occasionally one of considerable size occurs, separating the peritoneal covering and forming a tumour, generally upon the superior surface. Such lacerations may be produced during labour, and a slow accumulation of blood may take place beneath the capsule, death resulting from rupture into the peritoneal cavity.

RECOVERY FROM TUBAL DEAFNESS CAUSED BY A SARCOMA.

BY

SAMUEL LODGE, O.B.E., M.D.,

AND

WILLIAM OLIVER LODGE, M.D., F.R.C.S.E.,

BRADFORD.

(From the Aural Department, Royal Halifax Infirmary.)

THE following case is one of removal from the soft palate of a sarcoma which resembled clinically the type of endothelioma found in this situation.¹ As a result of relief of pressure on the Eustachian tube the patient recovered from unilateral deafness of eight years' standing.

An active man engaged in responsible affairs became deaf in the right ear at the age of 35 and noticed a swelling at the back of the mouth three years later. At the age of 40 he could only hear ordinary conversation close to the right ear. The swelling grew larger internally and began to project outwards behind the angle of the jaw. The voice had a nasal intonation, but there was no interference with breathing or swallowing.

The smooth yielding tumour occupied the right side of the soft palate and nasopharynx, the tonsil being displaced medially, and was slightly movable on bimanual palpation. The drumhead of the right ear was withdrawn and with the C 256 tuning-fork bone conduction was relatively increased. With the stem of the vibrating fork on the vertex the sound was heard loudly in the right ear; by air conduction C 1024 was heard well, C 128 not at all. The left ear was normal. Systemic examination, including a blood count, revealed nothing abnormal.

Operation.

General anaesthesia was induced with chloroform and continued through a laryngotomy tube. The tumour, which extended deeply into the pterygo-maxillary and submaxillary regions, and was

surrounded with a false capsule, was dissected away. The walls of the cavity were coagulated by diathermy. A week later a tube of radium emanation was placed in the depth of the cavity and another towards the root of the tongue; these were secured in position for twenty-four hours by packing.

On section the tumour proved to be a spindle-celled sarcoma; portions of muscular tissue were seen to be invaded.

After-Treatment.

As soon as the sloughs had separated the patient was referred to Dr. William Mitchell for x-ray treatment, and five exposures were given. Three months later the drum was less retracted, and on inspection with Hay's pharyngoscope the Eustachian orifice appeared normal. After one or two inflations with the catheter the hearing for the watch and voice was completely restored. Rinne's test was positive, though air conduction was still a few seconds less in excess of air conduction than on the left side. Four years after the operation there was no sign of recurrence, and the hearing was normal.

What was the pathological condition of the right ear from which the patient recovered so promptly when the patency of the Eustachian tube was restored? In three cases of obliteration of the Eustachian tube by malignant tumours of the nasopharynx Brock found serous exudation into the tympanic cavity and its adnexa, attributable to hydrops *ex vacuo* rather than to inflammation. Karl Beck of Heidelberg, experimenting with dogs, closed the tube with wooden plugs, or, as was found more effective, with the thermo-cautery. After killing the animals, microscopic examination revealed hypertrophy and cellular infiltration of the mucous membrane, some bony thickening, and a sterile exudate containing polymorphs and lymphocytes. According to Habermann² this condition differs from chronic catarrh of the middle ear, in which proliferative changes in the tympanic mucosa are identical with those of hypertrophic rhinitis. In our case, in which closure of the Eustachian tube was probably gradual and possibly intermittent, there were no subjective symptoms of fluid in the tympanic cavity, nor could any fluid exudate be seen through the drum.

Only by the finest discrimination between the forms of chronic deafness can we hope to judge beforehand whether operations on the nose and throat will restore hearing.

CONGENITAL OCCLUSION OF DUODENUM.

BY

ANDREW V. MAGEE, M.B., CH.B.GLAS.,

SENIOR RESIDENT ASSISTANT MEDICAL OFFICER, BOOTH HALL INFIRMARY FOR CHILDREN, MANCHESTER.

DR. H. C. CAMERON, in the Linnleian Lectures, delivered last year,¹ discussed in the first lecture vomiting in infancy due to obstruction from developmental defect in the upper alimentary tract. The following case is reported because, as Cameron says, "the diagnosis, supported by a characteristic radiographic appearance, is often not difficult, and because, sometimes at least, we may hope to save life by means of a timely operation following upon early diagnosis." The condition, however, appears to be very rare. Only one case² has been reported in this infirmary, with about 3,500 admissions annually, in nine years.

A male infant, aged 5 days, was admitted to Booth Hall Infirmary, Manchester, on January 15th, 1926. There was a history of vomiting everything taken by the mouth since birth. The patient was the weaker and smaller of uniovular twins and weighed 4½ lb. at birth. The pregnancy and labour were normal and the parents and their children were healthy.

On examination the heart and lungs were found normal. The tongue and pharynx were red and congested. The abdomen was not distended, but some fullness was seen and felt in the epigastric region. No intestinal peristaltic waves were seen; there was no jaundice. The anus and rectum were normal. X-ray examination of the stomach was not done.

Appearance of the Tumour.

Vomiting persisted after admission in spite of medical treatment. After a feed, or sometimes not until after two or three feeds, food welled up into the mouth in large quantity. It was composed of curdled milk and was not bile- or blood-stained. The capacity of the stomach was very great, and gastric "wash-outs" returned unstained.

The stools, which were passed with ease, were composed of meconium, glairy mucus, and bile.

The nature of the lesion was suspected, and surgical treatment (gastro-duodeno-enterostomy) was considered, but the child had already undergone five days' starvation, and was in a condition of dehydration and inanition. It was therefore put in an incubator and rectal and subcutaneous salines given every four hours. Two days later (seventh day of life) it died, effortless vomiting persisting until the end.

Post-mortem Examination.

The liver reached to just above the umbilicus, and the lower border of the

A, Pyloric valve. B, First part of duodenum. C, Common bile duct. D, Fibrous band. E, Mass of lymphoid tissue. F, Remainder of duodenum. G, Small intestine. H, Pancreas.

stomach nearly to the symphysis pubis. The gall bladder was distended and the part of the stomach wall in contact with it was bile-stained. The stomach was greatly dilated and contained curdled milk. The pyloric valve was fully dilated.

The first part of the duodenum ended in a dilated, dome-shaped diverticulum. The occluded end was firmly connected by a strong fibrous band to the head of the pancreas. The remainder of the duodenum (second and third parts) began, at the upper end, as a bulbous dilatation, into which, almost at right angles, ran the common bile duct. A firm, nodular mass in the wall of the gut near the entrance of the duct proved, on histological examination, to be a mass of lymphoid tissue. A band, composed entirely of fibrous tissue, stretched from the occluded end of the first part of the duodenum to the head of the pancreas. Midway in its course it enveloped the bile duct and remainder of the duodenum. The pancreatic duct, although not traced, did not enter the gut in the region of the bile duct.

The remaining organs in the body appeared normal.

Early diagnosis is essential in these cases. Unfortunately, in the case recorded more than five days elapsed before the child was brought to hospital and a diagnosis made.

I have to thank Dr. J. D'Ewart, medical superintendent of the infirmary, and Mr. Robert Ollerenshaw, consulting surgeon to the Manchester Union, for permission to publish these notes. I have also to thank Dr. G. D. Dawson, pathologist to the Manchester Union, for the histological examination and identification of the various parts removed at the post-mortem examination.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

SPONTANEOUS REDUCTION OF ACUTE INTUSSUSCEPTION.

SPONTANEOUS reduction of an intussusception and the verification of the diagnosis by laparotomy is of sufficiently uncommon occurrence to merit record.

A male child, aged 1 year and 6 months, was seized at 1.30 p.m. on March 3rd, 1926, with acute abdominal pain. It vomited on four occasions during the next four hours, and a motion passed was blood-stained. The child had always been constipated, but there was no history of previous attacks.

The child when first seen at 6 p.m. was suffering from agonizing abdominal pain. Across the abdomen, just below the umbilicus, a well marked tumour was present, and examination by the rectum revealed typical red-currant jelly.

The patient was admitted to the infirmary at 7.30 p.m.; it was screaming, and the legs were drawn up to the abdomen. A tumour was palpable below the umbilicus, and on rectal examination the gloys were blood-stained, but no typical red-currant jelly was found.

Operation was arranged for 9 p.m., but soon after the last examination the patient fell asleep, and remained asleep until 8.45 p.m. When seen at 9 p.m. it was quiet and contented and abdominal palpation and rectal examination were completely negative. No enemata had been given, but in view of the

definite findings at 6 and 7.30 p.m. it was decided to perform laparotomy.

The abdomen was opened by a paramedian incision. The small intestine for a length of 5 to 6 in. from the ileo-caecal valve was markedly thickened, congested, and rather distended, with haemorrhagic spots present at various points on the peritoneal surface. The thickening and congestion were most marked in the last 1 to 2 in. of the ileum, and the proximal portion of the intestine implicated presented a ring-like appearance as if one part of the intestine was invaginated slightly into the next part. The gut was quite viable, but the mesentery was congested, inflamed, and swollen, and the glands in the mesentery were enlarged. The "dimple" characteristic of the reduced intussusception was present on the lower outer wall of the caecum. The abdomen was closed, and on the next day one blood-stained motion was passed. On March 21st the patient was discharged after an uninterrupted convalescence.

Presumably, had no operation been performed this case would have been labelled "gastro-enteritis" or a vague "food poisoning," and one can only conjecture how many more such cases have been likewise labelled. In this case the definite physical signs at 6 and 7.30 p.m. made one chary of leaving well alone when the child was again examined at 9 p.m.

I am indebted to Mr. K. M. Duncan, F.R.C.S., for permission to publish this case.

DAVID J. DAVIES, M.R.C.S., L.R.C.P.,
Resident Surgical Officer, Preston Royal Infirmary.

CYSTIC DEGENERATION OF A UTERINE FIBROID WITH PARTIAL EXTRUSION.

THE patient whose case is recorded below was brought to the Royal Salop Infirmary, Shrewsbury, in a condition so serious that no detailed history could be obtained.

A woman, aged 46, was admitted to the infirmary suffering severely from shock, with signs of haemorrhage. She stated, that, having been much troubled by "pains in the stomach and constipation," she had taken an aperient the previous evening, and on waking during the early hours of the morning had found her "bowels lying out on the bed."

A large mass of what at first appeared to be decomposed coils of intestine was seen lying between her thighs. She was immediately taken to the theatre and an anaesthetic administered. The prolapse, which weighed about 4 lb., consisted of a horribly putrid, grey, semisolid mass, held together by interlacing fibrous bands. There was very little haemorrhage, and no blood vessels could be seen. The external portion of the prolapse was clamped and excised. It was then seen that it had come down through the vagina, which was distended by a continuation of the growth. On introducing the hand into the vagina alongside the prolapse, the cervix was found to be dilated sufficiently to enable the hand to be passed into the uterus. The interior of the uterus was filled with a soft friable growth which was densely adherent to the uterine walls by tough fibrous bands. The uterus formed part of a hard rounded tumour filling the pelvis and extending up to four inches above the umbilicus. At the upper margin of the tumour a pedunculated fibroid could be felt.

It was decided to perform hysterectomy. A considerable amount of blood clot and offensive serum was found lying among the coils of intestine; this was seen to be coming from the right Fallopian tube, which was distended and had ruptured. The uterus was pale and oedematous. In front it was adherent in its upper part to the parietal peritoneum by recent adhesions and to the omentum and transverso colon by much firmer adhesions. The omentum was clamped and tied off, but it was necessary to dissect a flap of peritoneum off the uterus to free the colon. This flap was then folded over on itself and sutured, thus covering in the raw surface. The veins of the broad ligament were very dilated, especially on the left side.

Owing to the uterus being firmly fixed in the pelvis some difficulty was experienced in securing the uterine vessels. This was overcome by working down the broad ligament on one side, dividing the cervix, and securing the broad ligament on the opposite side from below upwards (Kelly's method). The peritoneal cavity was drained by a large tube brought out through the vagina.

Examination of the uterus showed that it was the site of numerous fibroids. The small pedunculated fibroid situated on the fundus had undergone calcareous degeneration. One large interstitial fibroid showed typical red hepatization. The main portion of the growth, however, consisted of a large submucous fibroid, which had undergone cystic degeneration. This filled the uterine cavity, and had sloughed; it was this sloughing mass that had been expelled from the uterus.

The pathologist reported that sections taken from the uterine wall, and the fibroids, had the appearance of a fibromyoma undergoing necrosis, and that there was no evidence of any malignant change.

I was afterwards able to get a more detailed history. The patient had had a child nineteen years previously, but no further pregnancies. Menstruation had been regular, but during the last four years had been excessive, lasting eight days. She stated that thirteen months ago she passed a "fleshy lump." She had noticed enlargement of the abdomen for two years, but had suffered no inconvenience until a month before admission, when she was much troubled by backache and abdominal pain accom-

panied by a slight but very offensive vaginal discharge. This, however, was not sufficiently severe to prevent her doing her usual household work.

As might be expected, the patient's convalescence was not uneventful. There was profuse purulent discharge from the drainage tube, but the temperature became normal on the third day; on the sixth day it rose again slightly, and this was accompanied by pain and some swelling of the left leg and thigh. This rapidly subsided under treatment, and all went well until the twenty-first day, when she suddenly died of pulmonary embolism.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

ST. PANCRAS DIVISION.

THE TREATMENT OF HEART FAILURE.

At a meeting of the St. Pancras Division of the British Medical Association, held at the Association House, Tavistock Square, on April 20th, Professor F. R. FRASER delivered an address on digitalis in the treatment of heart failure. Dr. GEOFFREY EVANS, chairman of the Division, presided over a large attendance.

Professor FRASER said that he intended to confine his remarks practically to the action of digitalis in auricular fibrillation. Pharmacologists, studying the effects of digitalis on animals, gave a great number of possible actions of the drug, but in the human subject, with therapeutic doses, the actions were really reduced to three, and possibly two of these were identical. The first of these actions was to slow the sinus node, the pacemaker of the heart, but it was no use to expect in this way to slow the heart when it was quickened by any cause other than heart failure, and even such slowing action as was brought about was not very powerful. The second action of digitalis, a powerful and constant one, was to cause delay at the auriculo-ventricular node in the conduction of the impulse from the auricle to the ventricle. About the third action there was a good deal of controversy. Some authorities maintained that digitalis increased the force of ventricular contraction; others denied this stoutly. Most of the British school were rather sceptical about any action of value in therapeutics upon the ventricular muscle, but evidence seemed to be accumulating that there was some such action, and if the action existed it meant that digitalis was of some use, not only in auricular fibrillation (which followed from its second action just stated), but in all cases of heart failure when the ventricular action was not so good as it ought to be. But this third action, like the first, was in any case a very poor action compared with the second. Like all powerful drugs, digitalis could do harm, and the maximum beneficial dose was very near to the toxic dose. Workers in New York had stated that with 15 c.m. of good tincture, comparatively fresh, for every 100 pounds of body weight, a patient would be fully digitalized. Digitalis was completely absorbed from the stomach within six hours, therefore there was no purpose in giving digitalis hourly or two-hourly, nor, on the other hand, in waiting for a day before giving a second dose. Six hours was the right interval, so that there was a logical basis for the customary procedure of giving digitalis three times a day. Digitalis was excreted by the kidneys and bowels, and destroyed in the liver and heart muscle. It was calculated that the tincture of digitalis was eliminated or destroyed at the rate of 22 minims a day. Thus a dose of, say, 15 or 20 minims a day would not result in an increasing concentration of the drug in the body. Some patients could take 30 minims a day without accumulating it, but it was necessary to watch larger doses very carefully, because more digitalis was being given than could be destroyed. The toxic phenomena of digitalization were, in normal persons, drowsiness, nausea, and vomiting, occasionally diarrhoea. If digitalis were pushed still further actual heart-block would be caused. In the case of persons with a diseased heart, digitalis affected the diseased portion of the heart before the other effects were produced, and here dropped beats due to blocking indicated toxicity. In auricular

fibrillation, where a dropped beat would not be recognized, the first sign might be coupling. Apart from the limitations thus suggested, there were certain types of cases which did not seem to respond to digitalis as well as might be expected. A patient whose heart beat did not become slower was a patient who had an active infection. Another patient with auricular fibrillation and acute rheumatism might even have nausea and vomiting with digitalis before a slowing effect was perceived. Professor FRASER showed a number of charts to illustrate different types of cases. An additional output of urine, he said, was not due to any diuretic action of digitalis, but simply to an improvement in the circulation. With a mild degree of heart failure the pressure was even higher than when the patient was comparatively well; apparently there was a reaction in the periphery, and the pressure increased as the patient got worse. If digitalis were given in that state the pressure would fall. Under digitalis the pressure would rise or fall or remain constant according to the need of the patient. A raised blood pressure was never a contraindication to digitalis; usually it was the reverse. If digitalis were given whatever the abnormality in pressure it would bring about a closer approximation to the normal. He also advised that whatever preparation of digitalis was chosen, one preparation alone should always be employed; the necessary experience would not otherwise be acquired. He personally preferred the tincture, for reasons which he gave. He also mentioned the danger of intravenous injections of strophanthin if the patient within a period up to three weeks previously had had digitalis.

Dr. P. P. DALTON recounted a case of auricular flutter with senile changes in the heart, which he regarded as an ideal case for intensive digitalization. The patient, however, did not react at all well, and toxæmia was suspected; now Professor FRASER had made it plain that in cases where the heart was being poisoned digitalis would not act in doses short of toxic. Professor FRASER had mentioned only three actions of digitalis; Mackenzie thought there was another—namely, that the afferent fibres of the vagus were stimulated by digitalis to receive more impressions than they otherwise would. He asked whether the giving of digitalis for two or three days before operation would be likely to excite the vagus and increase the danger from anaesthesia.

Dr. A. J. CLARKE asked whether there was a nervous plexus in the auricle, or whether the conductivity was purely muscular. He asked also over what time the 15 c.m. of digitalis per 100 pounds of body weight was given, and Professor FRASER replied: Rapidly, so as to prevent elimination. Another question referred to the risk of giving large doses of digitalis if the previous quantity of digitalis taken was not known; in a case of high blood pressure, in which there were signs of heart failure, was there any danger of apoplexy in giving digitalis?

Professor FRASER, in reply, said that digitalis had the same actions in acute infections as in other states, but the order of the actions was disturbed, so that the toxic actions preceded the beneficial, and the patient would vomit before the pulse rate slowed. In pneumonia he gave digitalis continuously, because he believed in the third action to which he had alluded. In high blood pressure there was no danger from digitalis at all; the tendency was for the pressure to come down. As to any danger in giving digitalis after previous unknown digitalization, the case was rather different from that of strophanthin; strophanthin was administered intravenously, whereas digitalis was given by the mouth, and then vomiting afforded a safety-valve. The auricle, so far as was known, had a purely muscular conductivity. With regard to vagus inhibition during anaesthesia, it was supposed that if a patient were digitalized completely there would be a vagus inhibition, and it was a good tradition that atropine should be given to the fully digitalized patient. With regard to stimulation of the afferent fibres of the vagus, there was no evidence for or against this theory; it was purely a hypothesis.

The CHAIRMAN commented upon the way in which scientific findings had been correlated in the lecture with clinical medicine; and a hearty vote of thanks was accorded to Professor FRASER.

Reports of Societies.

THE CLINICAL SIGNIFICANCE OF THE RESPIRATORY METABOLISM.

At a meeting of the Medical Section of the Royal Society of Medicine on April 27th, Dr. HUGH THURSFIELD presiding, there was a discussion on the clinical significance of the respiratory metabolic rate. The discussion was confined chiefly to the so-called basal metabolic rate—that is, the absorption of oxygen and output of carbon dioxide (respiratory exchange) measured in the morning before breakfast, some twelve hours after a light meal taken the evening before.

Dr. E. P. POULTON, in opening the discussion, said that the methods of indirect calorimetry—direct calorimetry was not used as a clinical method—might be divided into the open-circuit method, where air from the atmosphere was breathed through mask and valves and the expired air collected, and the closed-circuit method, where the oxygen absorption alone was determined. Dr. Campbell and he had attempted to combine various principles described by other workers into a new type of apparatus which he demonstrated. It was so constructed as to permit the results for oxygen and carbon dioxide to be obtained during the actual experiment, so that it was possible to be quite certain how constant the metabolism was from one period of five minutes to the next, and there was no waste of time with subsequent analysis. The patient breathed ordinary air; the experiment could be prolonged indefinitely provided the source of the oxygen was pure, and, if required, a volumetric tracing of the respiration could be made. Turning to the clinical significance of basal metabolism determinations in thyroid disease, Dr. Poulton said that in hyperthyroidism the basal metabolism was raised, and in cretinism and myxoedema it was lowered. But in using the basal metabolism as a method of diagnosis it had to be remembered that certain other conditions, such as fever and leukaemia, brought about a raised metabolism, while starvation, underfeeding, and Addison's disease caused a lowered metabolism. An observation of the basal metabolism might be of value in excluding hyperthyroidism as a cause of wasting. Certain patients had well marked signs of Graves's disease, and yet had a normal metabolism; these had been described as border-line cases. As a guide to treatment the basal metabolism was of very great value, not only in cases of exophthalmic goitre, but also in determining the right dose of thyroid to give in cretinism and myxoedema. In obesity the difficulty was to arrive at a correct standard of comparison. If the metabolism of the healthy subject before he became fat was used as a standard, then the basal metabolism of obesity was usually abnormally high—a surprising fact, considering that adipose tissue by itself probably had a very low respiratory exchange, and tended also to prevent loss of heat. An increased metabolism of this kind might be explained by an increased intake of food, on the analogy that fasting produced a lowered metabolism; but some observations by Plaut pointed to the possibility that in these cases it was not so much the basal metabolism that was at fault as the so-called specific dynamic action after the intake of food. In conclusion, Dr. Poulton referred to some observations by Dr. Campbell and himself on the effect of exercise on the respiratory exchange of a patient with severe bronchitis and asthma. As a result of exercise the respiratory quotient was found lower than among normals, while the total oxygen intake remained the same, and treatment with oxygen caused a rise in the quotient to about the normal value. He thought that there might be some qualitative alteration in metabolism, due to exercise, in patients who were suffering from chronic oxygen want.

Dr. C. M. WILSON said that a discussion of this nature would be justified if it could be shown that these measurements supplied something in diagnosis and treatment which clinical observation alone did not supply. In diagnosis the method was useful in distinguishing a non-toxic goitre in a nervous woman from a toxic goitre causing nervous symptoms. It was also useful in a group of cases common at

neurological hospitals in which the patients were nervous women with palpitations, some loss of weight, and other symptoms which might or might not be due to hyperthyroidism. A diagnosis could be made in this group by means of these measurements when clinically such a diagnosis could only be suspected, and it could be made at an early stage of the disease when treatment was likely to be far more effective than if it was postponed until the diagnosis on clinical grounds could be established. There were certain cases also of hypothyroidism stopping short of myxoedema which showed a definitely lowered basal metabolic rate, and these cases cleared up with the administration of thyroid extract. In brief, in diagnosis, though the measurements were not necessary for the confirmation of frank exophthalmic goitre or myxoedema, they were very useful in making an early diagnosis before the case was obvious clinically. In treatment the measurement of the basal metabolic rate did not enable one to say whether x rays or surgery were to be preferred in the management of exophthalmic goitre, but when the choice of treatment had been decided it was essential in the control of that treatment. He regarded it as unsafe to treat exophthalmic goitre with x rays unless the treatment was controlled by the basal metabolic rate, for such measurements not only prevented the treatment from being carried too far, but also from being stopped, through excessive caution, at too early a stage. The measurements did not indicate which were suitable cases for surgery, but they did indicate the right time for surgery, which was one of the three factors in successful operation, the others being the right choice of case and the skill of the surgeon. He believed that if an operation was done on a rising metabolic rate there would be trouble. Altogether these measurements lent precision to prognosis, and with regard to diagnosis and treatment they gave an element of safety which, so far as he knew, other observations could not supply.

Dr. GARDINER-HILL stated some conclusions gathered from between three and four thousand examinations at St. Thomas's Hospital during the last five years. The open-circuit method had been used; the closed circuit had been tried, but the results obtained in the open circuit with the Haldane-Douglas bag were held to be more consistent. One of the chief advantages of the bag was that the air breathed was more nearly normal than in the Sanborn apparatus. There seemed to be no doubt that in thyroid disturbance these determinations were of considerable value. In the diagnosis of early or latent cases of myxoedema much help had been afforded. In certain cases of sterility or repeated miscarriages where the gynaecologist could find no local cause there was a low basal metabolic rate, and pregnancy had followed administration of desiccated thyroid extract. The metabolism in pituitary disturbance was found generally within or only just outside normal limits.

Dr. R. D. LAWRENCE was not so optimistic as Dr. Wilson with regard to the value of these estimations over and above what might be ascertained from ordinary clinical observation of the pulse, weight, tremor, and so forth. He felt that a great deal of quite unnecessary work was being done. The part of the test which had interested him, however, was the respiratory quotient, which was definitely lowered in all fairly severe cases of Graves's disease. He attached a good deal of prognostic significance to a very low respiratory quotient, and thought that such patients were in a bad condition, and certainly not at the moment suitable for operation. He had been applying, with some success, the respiratory measurement to the ascertainment of the point at which Graves's disease, with upset of the carbohydrate metabolism (the condition in about 50 or 60 per cent. of the cases), passed over to Graves's disease in which true diabetes had ensued.

Dr. REGINALD HILTON spoke of the wide margin of error in these determinations. Errors were not avoided by the use of the Douglas bag, though this method was preferable to the oxygen-absorption method. It was very comforting to think that the progress of a disease could be measured numerically, but he rather agreed with Dr. Lawrence that these determinations were rarely necessary. They helped occasionally, but the clinician could very generally decide

the question without their aid, and he knew that some surgeons who once used the method regularly had now given it up. It was a useful control, but it could only confirm, not replace, the findings of the clinicians.

Dr. Poulton briefly replied.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.

A CLINICAL meeting of the Aberdeen Medico-Chirurgical Society was held on April 1st, the President, Dr. J. CROMBIE, in the chair.

Dr. A. G. ANDERSON showed a case of amyotonia congenita in a girl aged 12. The main features were the great flaccidity of the muscles, the diminished reflexes, and the fantastic attitudes in which the child could be placed. The child could remain sitting up but was unable to raise itself into a sitting posture when lying on the back. He also showed a man, aged 21, suffering from pseudo-hypertrophic paralysis which began between the ages of 14 and 15, a rather unusual feature. There were eight in the family; the eldest was affected, the five next were normal, and the two youngest suffered from this disease. The patient could walk fairly well and was able to pursue his studies at the university.

Dr. A. W. HENDRY showed a woman, aged 25, with well marked signs of acromegaly. She was seen first about a year ago, complaining of headache and fits of an epileptiform nature which occurred every four to seven weeks. She had noted the enlargement of the jaw, hands, and feet when she was 18. The nervous system was quite normal, but an x-ray examination showed a greatly enlarged sella turcica.

Dr. JOHN CRAIG showed a little girl who developed whooping-cough in December, 1924. There were no convulsions, and no unexplained fever, but she noticed on getting up in January, 1925, a weakness of the right hand, arm, and leg. The case was one of undoubted infantile hemiplegia. Dr. Craig mentioned that athetosis was more common in cases of infantile hemiplegia than in adults. The case was shown as illustrating a rare sequel of whooping-cough.

Mr. G. H. COLT showed a female patient, aged 20, who had suffered from a severe non-compound fracture of the right frontal bone. The unconsciousness on admission was not profound and she had bleeding from the right ear. A large trephining operation was performed the night of admission, and with the exception of a slight recession of the right eye, a slight inconstant nystagmoid movement, and loss of memory for names, not faces, she had made a very good recovery. The question of compensation was discussed at length.

CANCER RESEARCH.

A MEETING of the Derby Medical Society was held in the board room of the Royal Infirmary on April 15th, with Dr. HUGH BARBER, the President, in the chair, when Dr. S. MONCKTON COPEMAN, F.R.S., read a paper (illustrated by means of lantern slides) entitled "Some recent investigations on cancer."

Dr. Copeman gave a brief account of the work of the Departmental Committee on Cancer appointed in 1923 by the Ministry of Health, and of the memoranda and more detailed reports published under its auspices. In this connexion he dealt more particularly with the question as to whether mortality from the disease was actually increasing. As the outcome of recent statistical study this had been shown definitely to be the case, even when every allowance was made for "ageing of the population" and for improved diagnosis and accuracy of certification. The main portion of the paper was concerned with a description and discussion of recent experimental work on cancer, with special reference to that of Dr. Gye and Mr. Barnard on the discovery, isolation, and culture in a special medium, of a filter-passing micro-organism which not improbably constituted the specific virus of the disease. He also mentioned the investigations by Dr. Lumsden of the cure by inoculation of an immune serum of sarcomatous tumours experimentally implanted in the rat.

After summarizing the detailed reports by Dr. Jane Lanc-Clayton on cancer of the breast and uterus, made on behalf of the Departmental Committee, and of the Public Health Committee of the League of Nations; Dr. Copeman discussed the question of racial incidence of the disease generally and its selecting various organs of the body. He also dealt with the ultimate results of operative procedure in relation to the stage of the disease at which the patient came up for treatment, and the completeness, or otherwise, of the operation performed. Dr. Copeman referred briefly to a method of palliative treatment for inoperable cases of cancer by means of a dietary depleted so far as possible of foodstuffs of animal origin, containing vitamin A. In certain cases in which progress of the disease was not specially rapid adoption of this method had been found beneficial in bringing about marked increase of body weight lasting over considerable periods of time and accompanied by partial or even complete alleviation of pains.

TREATMENT OF ECLAMPSIA.

At a meeting of the Newport Medical Society on March 31st, the President, Dr. S. HAMILTON, in the chair, Dr. R. GLYN MORGAN read a paper on the treatment of eclampsia.

Dr. Glyn Morgan stated that according to the Registrar-General's returns some six hundred women in Great Britain and Ireland lost their lives annually from eclampsia. The maternal mortality rate, according to the committee appointed by the Congress of Obstetrics and Gynaecology in 1922, was 22.5 per cent., while the foetal mortality rate was about 46 per cent. Some fifty years ago the maternal mortality rate in eclampsia was given as 22 per cent. Prophylaxis was of the utmost importance, and it was disastrous if a woman who had been diagnosed as suffering from a late toxæmia of pregnancy should develop eclamptic fits. In the present unsatisfactory state of knowledge innovations in treatment should be avoided, and those measures should be selected which involved the lowest mortality rate for the mother and child and a minimum of subsequent injury to the mother. Very strong evidence had been produced as to the safety of conservative measures and the danger of radical procedures in the treatment of the disease. Surgical treatment in eclampsia was much more harmful than allowing the child to remain in *utero* during medical treatment. Caesarean section was an unsuitable treatment for eclampsia. The two lines of treatment which had given the lowest mortality rate were those advocated by Professor Stroganoff and by the Dublin school. The fundamental idea of the Stroganoff treatment was that the fits played a pre-eminent part in the results of the disease, and that everything possible must be done to prevent their repetition. Stroganoff relied chiefly upon stopping the fits by chloroform, chloral hydrate, and morphine, and the prevention of all possible external stimuli, while he left the patient to detoxicate herself by her own excretory organs. Eliminative methods played a much smaller part in his treatment than in that usually adopted in Dublin and England. The Dublin method was largely based on the theory that the toxæmia was due to intoxication from the bowel, and intestinal elimination was the essential factor. It had been claimed that the method had reduced the maternal mortality rate to about 9 per cent. All cases of eclampsia, whether mild or severe, were best treated with as little obstetric intervention as possible. The measures adopted should be those which involved a minimum of shock and trauma. Simple medical treatment according to the Stroganoff or Dublin method gave the best results.

Chronic Encephalitis Lethargica.

Dr. F. W. ROBERTSON read a paper on chronic encephalitis lethargica, and laid particular stress on the symptomatic polymorphism of the condition. He pointed out that the endocrine glands were sometimes involved, and mentioned a case which showed evidence of a transient pituitary enlargement. Paresis of the ocular muscles was seldom absent at some stage. The condition frequently caused character and moral changes, more especially in younger children, and was frequently responsible for the

"difficult" child. Ho then described "Parkinsonism" in detail, and gave the full histories of three patients suffering from this condition. Necropsy findings showed a perivascular infiltration, more commonly in the pons or mid-brain. He discussed the differential diagnosis, and stated that the commonest pitfall was disseminated sclerosis. Treatment was unsatisfactory; bromides and sodium luminal were useful for relieving pain; educational treatment and disciplinary training was often necessary for young adults.

Reviews.

THE SURGERY OF CHILDHOOD.

A STUDY of Professor FRASER'S *Surgery of Childhood* is likely to change the opinion of anyone inclined to think that the surgery of childhood is not sufficiently specialized to justify its separation from the main subject. The book is based on lectures delivered to the Edinburgh Royal Hospital for Sick Children. In its scope it shows little or no sign of such an origin; the surgery of childhood is taken as a definite entity, and full consideration given to every branch. This inevitably leads to some overlapping as regards matters usually dealt with in standard textbooks of surgery and orthopaedics, but perhaps no more than is desirable for clear presentation of the subject.

The work is divided into two parts: Part I occupies 425 pages of volume i, and represents the general surgery of childhood; the remainder of this and the whole of volume ii are devoted to regional surgery.

In the general section there is a chapter on infusion and transfusion by Mr. Norman Dott; for blood transfusion the citrate method is advised and described in detail. The author himself has written the chapter on anaesthesia, very reasonably pointing out that a surgeon is in a good position to offer advice on this subject. He selects ether as the anaesthetic of choice, advising the use of chloroform in exceptional cases and in infants. His advocacy of ethyl chlorido may not conform to the ideas of some specialists, but it should be noted that his views apply only to the open method of administration.

The section on rickets and tuberculosis of bones appears to us to be of exceptional value. The pathology of these subjects as far as it is known is clearly presented, and a vast amount of sound advice based on wide experience is given in relation to the treatment of these diseases. The detail in which the diagnosis and treatment of individual tuberculous joints is given makes this section an outstanding feature. The treatment of fractures is dealt with in some seventy-seven pages, and includes a short note on operative procedures for this condition; the section is illustrated with a number of x-ray photographs, a few of which, such as Nos. 66, 80, and 83, hardly seem worth the space they occupy. This is perhaps due rather to a failure in reproduction than to lack of detail in the original pictures.

In the regional section of the book, abnormalities and congenital malformations, as might be expected, take a prominent place. The section dealing with the intestinal canal is especially fully treated and well illustrated. Under the operative treatment of pyloric stenosis due attention is given to recent work; Rammstedt's operation and modifications of it are the methods which receive the most attention. The orthopaedic section presents a practical outline of the subject, is fully illustrated, and as an appendix has a useful note on the preparation of celluloid splints.

There is no bibliography, which seems to us an omission which might be rectified in a future edition. Much recent work is described and many references are made to rare conditions; details of the source of such information would make the book more valuable to those using it for reference purposes.

The work as a whole impresses us as being based on a substantial clinical experience tempered by an exceptional

critical faculty. The practical value is, on the whole, increased by a certain dogmatism in regard to indications for treatment—a dogmatism which is throughout controlled by a judicial attitude of mind. Altogether the book is a successful production, which will be of value both to the general practitioner and to the surgeon interested in children's diseases.

INDUSTRIAL PSYCHOLOGY.

THE book on *Industrial Psychology in Great Britain* which Dr. C. S. MYERS has just published is based on five lectures recently delivered by him in New York, but much new material has been incorporated. The opening chapter, on organization, gives a brief but interesting history of the development of industrial psychology in Great Britain. Its birth may be said to date from the formation of the Health of Munition Workers Committee in 1915, for that body, as Dr. Myers points out, carried out valuable pioneer investigations in munition factories upon hours of work in relation to output, lost time, and other questions of fatigue. In 1918 the Industrial Fatigue Research Board was formed to continue the work of the committee and extend it to other industries, and since that date the Board has published over thirty reports, one of the most important of which, on the subject of vocational guidance, was recently reviewed in these columns.

In the first few years of its existence the Industrial Fatigue Research Board conducted numerous inquiries into problems relating to specific industries, such as fatigue in the iron and steel trade, in the boot and shoe trade, and in cotton-weaving. The most recent policy of the Board has, however, been rather to study general problems of common interest to all industries, such as the introduction of rest pauses, accident causation, and ventilation. On the other hand, the National Institute of Industrial Psychology, which was founded in 1921, more especially aims at carrying out investigations at the request of individual industries or firms, and the training of investigators in industrial psychology. The work of the Board and that of the Institute are therefore to a large extent complementary. The Board conducts investigations with the detailed collaboration of the pure research worker, while the Institute applies the generalized results so obtained to a single factory. The employer of the factory usually desires immediate results which are not restricted to any one problem, but are related to any or all of the numerous questions which appertain to the human factor in industry. Many of these factors are dealt with by Dr. Myers in two chapters designated "Industrial fatigue" and "Movement study." He illustrates his exposition almost entirely by reference to investigations made in Great Britain during the last ten years, but the body of information available is so substantial that he does not need to omit any important aspect of the subject.

In his last two chapters Dr. Myers discusses vocational guidance and selection at some length, as is but natural, for the Institute of Psychology, under Dr. Myers's direction, has devoted a very large part of its energies to this particular field of inquiry. We are glad to think that the good work will continue even more vigorously in the future than in the past, thanks to very generous financial aid from the Carnegie Trustees. Vocational selection tests are now being applied by a large number of firms throughout the world, and the more progressive firms in Great Britain are gradually following suit. The Institute has devised appropriate tests for engineers, weavers, dressmakers, and other industrial workers, and also for clerical workers and retail saleswomen. Some of these tests are described in detail by Dr. Myers, with illustrations of the apparatus used. There seems little doubt that before many years have passed vocational and intelligence tests will be applied as a matter of course to every school child, and to most of the entrants into industry. What a world of misdirected effort will be saved thereby! Every employer interested in all questions relating to the physiology and psychology of industry, which are conveniently covered by the term "industrial psychology," cannot do better than read and digest this excellent little volume by Dr. Myers.

Industrial Psychology in Great Britain. By Charles S. Myers. London: J. Cape, Ltd. 1926. (5½ x 8½, Pp. 164; 18 figures. 7s. 6d. net.)

Surgery of Childhood. By John Fraser, M.C., M.D., Ch.M., F.R.C.S.E., Regius Professor of Clinical Surgery in the University of Edinburgh, Consulting Surgeon to the Royal Hospital for Sick Children, Edinburgh. In two volumes. London: E. Arnold and Co. 1926. (Med. 8vo: Vol. I, pp. viii + 604, 332 figures; Vol. II, pp. iii + 548, 256 figures. 42s. net the two volumes.)

GASTRIC FUNCTIONS IN HEALTH AND DISEASE.

It is sometimes said that there are too many formal lectures in medicine, not only in medical schools, but of an endowed character at institutions, such as the Royal Colleges. The latter lectures have the advantage of giving younger men an opportunity of correlating published work and bringing researches conducted by themselves to notice, as is eminently shown by Dr. J. A. RYLE's Goulstonian Lectures delivered before the Royal College of Physicians of London last year on *Gastric Function in Health and Disease*,³ now published with some additions in book form.

The lectures are based on five years' work with Relfuss's fractional test meals carried out on normal people, including the lecturer, and on the subjects of gastric disorders. From these data, which are interpreted in terms of the late Sir James Mackenzie's conception of dyspepsias as expressions of disturbed reflexes, the dyspepsias are divided into five groups, which, however, overlap to some extent: as sedentary dyspepsias; toxic and infective dyspepsias; psychogenic dyspepsias due to a local or distal organic condition, such as appendicitis or a fatty extraperitoneal hernia, termed by Professor F. Craven Moore reflex dyspepsia; and, fifthly, dyspepsias consequent on gross structural disease, such as malignant pyloric obstruction or hour-glass stomach, or to surgical modifications of the stomach, such as complications and sequels of a gastro-enterostomy. In a series of 267 unselected cases Dr. Ryle found that the last two groups of dyspepsias—the irritative and the mechanical—constituted 52 per cent., the toxic and infective group and the habit dyspeptic group 12 per cent. each, and the nervous group 24 per cent. of the cases. These various forms of dyspepsia are then separately described in detail.

Attention may be called to some of the conceptions formulated in these lectures; the two main types of the dyspeptic reaction are the "immediate" from the recently filled stomach, and the "delayed" from the emptying viscus; the provocative factors are either "pressor," producing exaggerated muscular action as in the irritative dyspepsias, or "depressor," causing relaxation or inhibition, as in dyspepsia due to fatigue or toxæmia. Among the toxic forms, that due to tobacco is an exception, as a pressor inhibition allows exaggerated vagus action so that a pressor effect results. Another causal factor is the physiological gastric habit of the individual which is part of his physical attributes; the anthropological relations of gastric and duodenal disease is a new problem, or rather the old one of diathesis revived, and this particular relation has recently been investigated by Dr. George Draper of New York and others. Dr. Ryle describes the normal or orthotonic stomach, the hypertonic, which is found in the vigorous, broad-chested, or lean individual with brisk reflexes, who may become the subject of duodenal ulcer, and the hypotonic stomach, as in the enteroptotic person. In the normal physical habitude the condition of the stomach may vary from orthotonus to at least slight degrees of hypotonus. These lectures are an admirable summary of thoughtful work, and are evidence of the Guy's spirit which Dr. A. F. Hurst has done so much to maintain. There are many points brought out, so to speak, in passing, such as the difference of the factors responsible for appetite and hunger, and the dependence of gastric flatulence on aerophagy, but enough has been said to show the high standard of these lectures.

A PUBLIC HEALTH TEXTBOOK FOR INDIA.

COLONEL C. L. DUNN, I.M.S., Director of Public Health in the United Provinces, and Professor D. D. PANDYA of Lucknow, have prepared a handbook⁴ to meet the needs of candidates for the diploma in public health in India and of medical officers of health in that country. In it are con-

³ *Gastric Function in Health and Disease*. By John A. Ryle, M.D., Lond., F.R.C.P. Oxford Medical Publications. London: Humphrey Milford, 26 charts, 8s. 6d. net.)

⁴ *Indian Hygiene and Public Health*. By C. L. Dunn, D.P.H., and D. D. Pandya, D.P.H., Camb. Calcutta: Butterworth and Co. (India), Ltd.; London: Butterworth and Co. 1925. (Med. 8vo, pp. xix + 679; 76 figures. 22s. net.)

sidered such subjects as water supply, ventilation, disposal of refuse and excreta, food, communicable diseases, housing and town planning, personal and school hygiene, climate and vital statistics, and sanitary law. The chapter dealing with the last subject occupies nearly half the book. Though applicable more or less to the whole of India, it deals specially with the United Provinces, containing all sanitary laws current in these provinces. These will be useful for reference to a health officer, but much increase the length and size of the book.

Under water supply, it is stated that 30 to 50 gallons a head a day are found sufficient in England (London has about 30 gallons and Glasgow 50). In hot climates, naturally, more water is required, and still more used, than in temperate regions, but the authors think that 50 gallons should be sufficient in India. The amounts supplied at present in eighteen of the chief cities of India are given in a table: only three come up to or near the standard desirable—Rangoon (54 gallons), Calcutta (40), and Bombay (39); some of the largest cities have only a third or a quarter of this—Lahore (11), Amritsar (13), and Lucknow (15) being among the lowest. The reason these cities manage with so low a supply is that the municipal water supply, usually good, is supplemented by wells, public and private; but the water from wells, especially private wells, in a city is usually contaminated. An article in the *Pioneer Mail* of February 26th last on the Bombay water supply states that, sixty years ago Bombay had a water supply of 10 gallons a head, which was found fairly sufficient; in 1892 the supply was increased to 38 gallons, and in 1915, after the construction of the Tansa dam, to 50 gallons a head. Even this amount has been found insufficient to give a constant supply throughout the day and new waterworks are under construction to double the amount. In India, and probably everywhere, it is not the water used which makes supplies insufficient so much as the water wasted. The only means of preventing this waste is to supply water by meter, like gas and electricity, not in unlimited quantities at a flat water rate. The latter, however, is the system in use in India, and for the most part in this country.

Under disposal of excreta it is stated that the water-carriage system has been introduced in most large towns in India, and is being extended, and that where a sufficient pipe water supply is available it is the best system. The great cities in the Indian plains have special difficulty in such disposal, owing to the flatness of the country and consequent want of fall. Calcutta and Rangoon, on large tidal rivers, are barely above water-level. In any case, water-carriage disposal is impossible without adequate pipe water supply, which is seldom available. The usual method of disposal is by removal and trenching, followed by cultivation of the trenching grounds. At best removal of night-soil in carts is a nuisance, and the trenching requires strict supervision. In an institution such as a jail, where labour is plentiful and under discipline, the system works well; elsewhere it shows better in theory than in practice. The account of the abominable *sandas*, or domestic well privy, the most insanitary nuisance in an Indian town, shows European readers what sanitarians in India have to contend with. The book is well got up, illustrations, type, and paper are good, and there are not many misprints.

BIOLOGICAL CONSTANTS.

Tabulae Biologicae is a collection of tables of biological statistics which have been prepared under the editorship of C. OPPENHEIMER and L. PINCUSSEN. The whole work will comprise four volumes of about 500 pages each.⁵ The first volume deals with statistics of pure physics, with physics as applied to biology, and with physical chemistry and its biological applications. Simple abstracts of constants and data are given without didactic comment.

The second volume deals, amongst other subjects, with the relation of biological processes to temperature, the physical chemistry of ferments, photo-chemistry, x rays,

⁵ *Tabulae Biologicae*. Edited by C. Oppenheimer and L. Pincussen and 90 contributors. In four volumes. Vol. I: Pure and Physiological Physics, Physical Chemistry and its Biological Applications. Vol. II: Thermodynamics, Ferments, Electrochemistry. Vol. III: Radiations, Biophysics, Secretions. Berlin: W. Junk. 1925. (Sup. roy. 8vo: Vol. I, pp. 522; Vol. II, pp. viii + 567, 25 plates, 47 figures. Price for four volumes, £18 bound, £9; not sold separately.)

radio-activity, general musculo and nervo physiology, and the chemistry of the secretions, including milk.

All workers in biological sciences are familiar with the prolonged search through literature that is often necessary in order to discover a biological constant, and most of those workers will at some time or another have regretfully compared the ease with which physico-chemical constants are to be found in "Landolt-Börnstein," with the difficulty of running to earth some simple constant in the biological sciences. The editors of *Tabulae Biologicae* have set themselves the task of preparing a book that will serve the biological sciences as the other book we have mentioned serves physics and chemistry.

The volumes under review consist, as has been mentioned, almost entirely of tables of constants, and therefore any detailed criticism is almost impossible. Reference to one or two subjects with which the reviewer is familiar shows that the collection of data has been carefully carried out, and that care has been taken to include the most recent and most reliable figures available.

To show the scope of their work, the editors, in an introductory leaflet, have prepared a kind of examination paper, the answers to which are to be found in the tables. Examples of these questions are:

"What is the lapse of time between immunization and the appearance of antibodies? What are the limits of the spectrum visible to the eye? How are white blood corpuscles distributed in the infant? What is the osmotic pressure of vegetable cells? What animals contain copper and in what quantities? How great is the combustion heat of lactic acid? How great is the conduction velocity in the ischiadics of the frog?"

These examples show the wide range of sciences for which data are supplied; they concern botany, zoology, physiology, anatomy, pathology, bacteriology, pharmacology, hygiene, and general medicine.

Tabulae Biologicae should prove a valuable help and time-saver to all research workers and teachers in the wide domain of biological science. It is a work that no laboratory can afford to be without, and all medical men should remember the existence of these volumes, for reference to them will frequently provide in a few minutes information that might otherwise require perhaps weeks of reading to collect.

The price of the four volumes is at present about £8 unbound and £9 bound. The volumes are not sold separately; this, in the circumstances, is a reasonable condition. The price also is reasonable, since the volumes consist almost entirely of tabulated material, and the cost of printing such matter is notoriously high.

NOTES ON BOOKS.

THE first volume of the *Collected Papers* of the Rowett Research Institute, Aberdeen, has been issued. The institute was originally opened for research work in agricultural science in April, 1914; its activity was suspended by the war, but in 1919 the scientific research work was reorganized, an experimental stock farm established, and an adequate library provided. Sir George Adam Smith, Principal of the University of Aberdeen, is the chairman of the governing body, which includes members appointed by that university and the North of Scotland College of Agriculture; the director is Dr. J. B. Orr.

Dr. G. H. KLÖVERKORN has translated into German and re-edited the short work on the examination of the faeces by Dr. S. L. BRUG, Director of the Central Army Laboratory, Batavia. The original work is sufficiently well known to need no further recommendation at the present day, and the translation and editing seem to have been ably carried out. The book is of the nature of a primer for the student in the laboratory, and gives an account of a few practical methods of examination which are simple and have been proved to be reliable, and not a bewildering multiplicity. The brief descriptions of the intestinal parasites and commensals are

adequate for the beginner, and include the Entamoebae, the intestinal Flagellata, *Balantidium coli*, *Giardia*, Blastocystis, and Coccidia. A second section of the work treats of the examination for, and recognition of, helminth ova in the faeces. There are eight plates with figures representing the various parasites and ova. Some of the latter are depicted although there is no reference to them in the text, notably *Schistosomum haematobium*, Fasciola, Fasciolopsis, Heterophyes, and one or two others. The author states in his preface that he has undertaken this translation because of the absence of such a work in German. Presumably he means works of such a small size as this, for the ground is covered by the books of von Prowazek, of Braun and Seifert, and of Neumann and Mayer, to name but three well known publications in that language. The present work is very convenient in size and is clearly printed on good paper. A few misprints will need correction in the next edition.

The second part of the eleventh volume of *The Medical Department of the United States Army in the World War* has been issued. It deals with various surgical matters, including empyema, maxillo-facial surgery, ophthalmology, and otolaryngology. The second part of volume xv, which deals with medical and casualty statistics, has also been received. We gave an account of the first part of this volume, relating to army anthropology, on December 27th, 1924 (p. 1202).

We have received volume v of the *Selected Contributions from the Peking Union Medical College*.³ It includes thirty-six papers on medical and allied subjects representing the activities of the college. The previous plan of collecting all the public investigations of the college in bound volumes has been found impracticable.

PREPARATIONS AND APPLIANCES.

A Lumbar Puncture Needle.

SURGEON LIEUTENANT COMMANDER W. I. GERRARD, R.N., writes: With the approval of the Director-General, Medical Department of the Admiralty, the following notes of an improved type of lumbar puncture needle are given. Acutely ill and unconscious patients cannot be placed in the position most suitable for lumbar puncture. It frequently happens in such cases that, when the needle has entered the spinal canal, the cerebro-spinal fluid, instead of dropping free from the needle opening, runs back along the outside of the

shaft; it is thus difficult to collect and a quantity is lost. In the modification of the puncture needle illustrated a small outlet pipe is fitted near the end of the needle. When the latter is *in situ* the stylet is withdrawn to just beyond the inner opening of the small outlet pipe, through which the cerebro-spinal fluid then escapes and is easily collected. Moreover, by means of the stylet, the rate of flow can be regulated. The needle has been successfully used in many cases, and has proved of much practical value. It is made by Messrs. Allen and Hanburys, London.

A Coat Lining with Air Cushions.

The "Gay" patent detachable lining, which can be used with any kind of overcoat or macintosh, contains two air cushions—one for the back and one to sit upon. These air cushions can easily be inflated or deflated in a few seconds without unbuttoning the coat, and, when empty of air, the lining is light, soft, and flat. This contrivance, which is chill and damp proof, is designed to give comfort to travellers, convalescents, and invalids. The provision of a cushioned seat and back rest, which does not add appreciably to the weight of the coat, will be welcomed by those who spend many hours out of doors in the country. When not required as a coat lining, it can be adjusted for use as a pillow for night travel, a soft cover for a hard chair, an emergency travel bed for an infant, or a hold-all; a light leather handle is provided for carrying. Three sleeveless designs are available: a back lining, at 21s.; a half-lining, at 22s. 6d.; and a whole-lining, at 25s. The lining is supplied by Messrs. G. MacLellan and Co., 22, Newgate Street, E.C.1, and at their warehouses in Glasgow, Liverpool, Manchester, and elsewhere.

² *Die Parasitologische Diagnostik der Menschlichen Fäzes*. Von S. L. Brug. Ins Deutsche übersetzt und neu herausgegeben von Dr. G. H. Klöverkorn. Leipzig: Johann Ambrosius Barth. 1925. (Med. 8vo, pp. 64; 41 figures, 8 plates. R.M.A. 3d.)

CAMBRIDGE MEDICAL WORTHIES.

At the social evening of the Royal Society of Medicine on Monday last, when the President, Sir ST. CLAIR THOMSON, received the guests, Sir HUMPHRY ROLLESTON, Regius Professor of Physic, Cambridge, gave an address on "Some worthies of the Cambridge Medical School." After observing that of the eighty presidents of the Royal College of Physicians of London since 1518, thirty-seven held Cambridge medical degrees, he went on to give accounts of worthies who were resident members of the University. He began with John Caius (1510-1573), who was the founder of scientific anatomy in this country and a Grecian after the order of Linaere, and, like Linaere, physician to three sovereigns—Edward VI, Mary, and Elizabeth. He was President of the College of Physicians on three occasions, for nine years in all, and did much for the College, founding its annals, designing the symbols and insignia, and in particular presenting to it the "staff of silver or caduceus with its head adorned with the arms of the College supported by four serpents to remind him by its material (silver) to govern with patience and courtesy, and by its symbols (serpents) with judgement and wisdom." Caius had been educated at Gonville Hall, Cambridge, of which he became a Fellow in 1533. He refounded Gonville Hall as Gonville and Caius College in the interests of medicine in 1557, and became master in 1558. His dislike of the vandalism of the times caused him to be persecuted by the vice-chancellor (afterwards Archbishop of Canterbury), and he died in London in 1573 in penury, for he had spent all his money on the College.

The next name mentioned was that of Francis Glisson, philosopher, physiologist, morbid anatomist, and clinician, who had described muscular irritability, and in 1650 wrote his book on rickets. His famous work *Anatomia Hepatis* (1654) made his name and capsule familiar to generations of students.

Of William Heberden, who before he removed to London was Linaere lecturer at St. John's College, Cambridge (1734-38), it was said: "He took careful notes of his patients, reading them over every month and then writing down in a kind of medical common-place book whatever he thought worthy of preservation; in this way he produced by the time he was 72 years of age his celebrated *Commentarii de Morborum Historia et Curatione*, which he entrusted to his son, William Heberden (the younger), with the injunction that it was not to be published until after his death." It was the last important medical treatise written in Latin.

Robert Glynn, afterwards Cloberry, was born in Cornwall in 1719, and educated at Eton and King's, which caused him when in practice to refuse to take fees from Cornishmen and Etonians. He had a great objection to opium and mercury, and when once was taken ill away from home he said to his physician that he was going to be very ill, but was on no account to be given any of "that vile drug, opium, or any preparation of it." When he recovered he asked whether his injunction had been obeyed, and the reply he received from his physician was, "If I had not you would not have been here to ask the question."

Sir Busick Harwood (1745-1814), a person of somewhat violent manners, was next mentioned; he was a Fellow-commoner of Christ's College, and became enthusiastic on the subject of blood transfusion, upon which, in 1785, the year after he was elected F.R.S., he wrote his M.B. thesis. He was appointed professor of anatomy in 1785 and retained the office until his death, although from 1800 to 1814 he was also Downing Professor of Medicine. He wrote a well illustrated *System of Comparative Anatomy and Physiology* (1795). He quarrelled with and challenged to a duel one of his colleagues (Sir Isaac Pennington) at Addenbrooke's Hospital, who treated the message with contempt and never answered. Pennington (1754-1817) was fifteenth wrangler in 1767; he was professor of chemistry for twenty years and Regius Professor of Physic from 1793 until his death, and for fifty years Linaere lecturer. He was succeeded, first

as Linaere lecturer and then as regius professor, by John Haviland (1785-1851). To Haviland, Sir Humphry Rolleston said, "the Medical School owes much more than is now realized, for had it not been for his influence and insistence the medical faculty might have been abolished, and it has been said that its subsequent success was largely due to his exertions. He was the first to give regular courses in pathology and the practice of medicine, and to make the medical examinations a real and rigid test instead of a rather farcical form, sometimes it has been whispered post-prandial, at least in point of time. As he wrote little, and personal memories die comparatively young, his name is seldom mentioned now, but if the doings of the medical school since his time be a monument to his saving grace, he could hardly have wished for a greater." Haviland was twelfth wrangler, and the next worthy mentioned, Sir Thomas Watson, was tenth wrangler (in 1815). He was also a Fellow of St. John's, Linaere lecturer, and junior proctor before he went to London to become physician to the Middlesex Hospital in 1827. Henry J. Hayles Bond (1801-1883) was regius professor for twenty-one years (1851-72) and took the rather unusual course of resigning twenty-one years before his death. His tenure of office was contemporary with a gratifying rise in the reputation of the medical school. This change indeed was urgently needed; for from 1833 to 1858 the average number of M.B. degrees granted in a year was less than four. In the fifty years, 1876 to 1925, approximately 2,500 first degrees in medicine or surgery have been conferred, the largest number being 80 in 1903; in 1917 there were 14, and in 1925 there were 68.

Coming down nearer to our own day, Sir Humphry Rolleston sketched the life of Sir George Paget, eighth wrangler, Fellow of Caius, for forty-five years physician to Addenbrooke's Hospital, and from 1872 to 1892 Regius Professor of Physic. He it was who, during Haviland's tenure of the chair, was instrumental in initiating clinical examinations for the medical degree; this was the first regular clinical examination held in the United Kingdom. "His share in the success of the Medical School has probably not been justly appreciated, for in addition to being the quiet but moving force behind his two predecessors he was instrumental in establishing the Natural Sciences Tripos in 1851, and took an active part in the early examinations. Further, it was during his term of office that the D.P.H. was started, and thus set an example to other universities and examining bodies."

Going on then to Sir George Murray Humphry, he said that it was nearly thirty years since his death, yet his pupils had an extremely vivid recollection of the most impressive teacher they ever had. "They recall him perched on his stool in the Museum, or leaning on his stick outside Addenbrooke's, with his mobile features, aquiline nose, glittering eye, and black hair, recalling Rembrandt's picture of the Jewish Rabbi, and by compelling attention 'the Ancient Mariner.'" "... He had the genius, perseverance, and collecting talent of the Chosen People. ... He found the Medical School insignificant, but left it what it is. ... A great anatomist, his book on the *Human Skeleton* (1858) made the dry bones to live, and was a quarry from which much ore was extracted by others." As a practitioner he was wonderfully shrewd, and many were the favourite aphorisms, such as "Eyes first, fingers next, ears last," that were remembered even now.

After a brief reference to William Harvey (1578-1657), the lecturer passed on to Sir Michael Foster, who, he said, "by creating the Cambridge School of Physiology, carried out Harvey's precept 'to search and study out the secrets of Nature by way of experiment,' and with Sir George Paget and Sir George Humphry created the modern Cambridge School of Medical Science." When he went to Cambridge his laboratory was at first half a room in the New Museums, his companion being the Plumian Professor of Astronomy James Challis (1803-1881). "Foster, ever anxious to encourage research and not without wise humour, initiated an investigation into the dissociation products of protein, which entailed the prolonged concentration of odoriferous fluids; not only did the Plumian Professor vacate his share of the premises,

but he spread about the tale of his experience, and, *post or propter*, Foster got progressively more elbow room."

Of Professor Alexander Macalister (1844-1919), who succeeded Sir George Humphry as Professor of Anatomy and held the chair for thirty-six years, the lecturer said that he "took a very broad view of human anatomy, like his successor, including embryology, histology, and anthropology, and was at once one of the most learned and most truly modest of men." Finally the lecturer said a few words about his immediate predecessor in the Regius chair, Sir Clifford Allbutt, declaring that, though wise with long experience, he "remained youthful in mind till the end, ever open to what was new as long as it was true, and yet he never seems to have made a mistake by backing some fallacious, though at first sight promising, departure. For sixty years he contributed to medical science, and much of what he pointed out has been so incorporated in common knowledge that his share is forgotten. He thought and worked on big lines, had high ideals, and was a most modest gentleman. His fame will increase when with the passage of years his work is seen in due perspective."

Sir WILLIAM HALE-WHITE, proposing a vote of thanks to Sir Humphry Rolleston, contributed further anecdotes, including the tale of Sir George Murray Humphry's systematic collection of centenarians who spurned neither wine nor tobacco; the pelican in St. James's Park which, having swallowed a Foreign Office paper believed to be important, was conveyed to a medical consulting room for an emetic; and the black-boned pigeons which, having figured in laboratory studies of Mendelian principles, subsequently formed part of Sunday dinners at Cambridge. During the evening various interesting exhibits were displayed and a programme of orchestral music was performed.

Nova et Vetera.

EARLY DAYS OF THE ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

THE Royal College of Surgeons of Edinburgh owes a debt of gratitude to the late Mr. Clarendon Hyde Creswell, formerly officer and sub-librarian of the College, for the painstaking work which has gone to produce the volume of historical notes dealing with the fortunes of that institution from 1505 to 1905.¹

Although the origin of barbers as a distinct craft may be traced back to 1092, when monks were forbidden to wear beards and members of the monasteries were trained in the arts of shaving and bleeding, and although two ranks were recognized, from the beginning of the thirteenth century, in clerical barber-surgeons and lay barbers, the official recognition of this calling in Edinburgh does not emerge until 1504. An extract from the burgh records of Edinburgh shows, however, that by this year the barber craft was a flourishing fraternity possessing a special altar in the Kirk of St. Giles for which they maintained a chaplain. The "seal of cause" or charter granted by the town council to the barber-surgeons in the following year contains a statement of their privileges and regulations. Every freeman of the craft was to pay one penny weekly and every servant or apprentice of the craft one halfpenny towards the upkeep of these religious observances. Before admission as a member of the craft each candidate required to be a burgess of the city and to be examined

"that he knew anofamea nature and complexioun of every member In manis bodie. And in lykewyse he know all the vayneis of the samyn thatt he may mak fleswthomen in dew tyme. And als thatt he know in quhilk member the signe hes domination for the tyme for every man aucht to know the nature and substance of every thing thatt he wirkis or ellis he is negligent."

The town council was also to provide once in the year a dead body of a criminal for the purpose of the mutual

instruction of the members of the craft. An important provision which indicates a high standard relative to the general intellectual advancement of the time was that no master of the craft was to take an apprentice in surgery unless he could both read and write. The craft also obtained an important privilege which at the present day would have been of great financial value, that no man or woman within the burgh was to make or sell any *aqua ritae*, except the masters and freemen of the said craft of surgeons.

Privileges of Barber-Surgeons.

When the barber-surgeons thus became one of the recognized crafts or guilds of the city, they stood ninth or tenth in order of seniority, the eldest being the Hatmakers, who had been incorporated since 1473. By 1582 we find that the Barber-surgeons took precedence as the premier guild among the crafts, which now numbered fourteen. The guilds assembled at intervals for the discussion of questions relating to the rights and privileges of the trades, their place of meeting being the Magdalen Chapel in the Cowgate, which belonged to the Hammermen, and which is still extant. Under the famous "blue blanket," the tradesmen's banner, the surgeons often rendered valuable service in the field in the troublous times of the sixteenth century occasioned by wars against "our auld inemics of England." George Leithie, a deacon of the barber-surgeons in 1527, received a yearly fee and pension by Act of Parliament for his services, and in 1542 we find that he again was one of those who received a grant for "passand to the bordouris for curing of all personis that hapnit to be hurt be the Inglis menne." In 1558, the country being threatened by an invasion from the south, the council was hastily summoned to take steps for the protection of the city. Robert Henderson, deacon of the barbers, and seven others were selected as a committee to arrange for putting the town in a state of defence, and the surgeon-barbers' incorporation undertook to supply 717 men, of whom 27 were barbers, in case of attack. A special charter granted by Mary Queen of Scots on May 11th, 1567, shows that the surgeons had by this time become indispensable to the army in the exercise of their craft. This "letter of exemption," as it is generally called, states that the chirurgians are no longer required

"to bear armour nor pass in battle in our hosts, raids, gatherings, assemblies, weaponshavings, or wars to be made by us or our successors . . . by land and sea within this our said realms or without the same; and also from all compearance and passing upon any inquests or assizes on actions criminal or civil. . . . Provided always that they be present with our armies ready to do their cure and duty to all such persons as shall have want thereof."

Professional Remuneration and Craft Fees.

There were numerous records, in the early days of the incorporation, of grants for special services, such as that already mentioned. James Henderson, deacon of surgeons in 1587, was entrusted by the town council with the duty of visiting "all persons who shall be infected with the sickness of pestilence," for which he was to receive a yearly stipend of £20. James Henderson was thus the first medical officer of health in Edinburgh, and his duties were performed with so much satisfaction to the council that it excused him from payment of any taxes levied on inhabitants of the burgh during his life. About the year 1581 the entrance fees to the incorporation were for surgeons £60 (Scots) and for barbers £40. An apprentice when he was "inbooked" had to pay 40s., and there was also a quarterly subscription from every master and freeman of the craft amounting to 6s. 8d. The incorporation appears to have obtained a considerable amount of revenue from fines imposed on its members for various offences, £5, for example, being the fine once paid by a member for uttering "unrelevant speeches" against the deacon, deforming the officer, and leaving the meeting without permission. For the more serious offence of having "beaten and stricken the deacon's wife, his children, and servant, and for having offered to put violent hands on the deacon himself," Francis Easton, apprentice to the deacon, was fined £50, as well as being obliged to sign a very humble apology. Another of the sources from which the calling derived an income is deserving of special mention.

¹ The Royal College of Surgeons of Edinburgh: Historical Notes from 1505 to 1905. By Clarendon Hyde Creswell, F.S.A.Scot., late Officer and Sub-librarian of the College. Edinburgh and London: Privately printed for the College by Oliver and Boyd, 1906. (Med. Bro. pp. xv + 262; illustrated. 10s. net.)

In 1614 an ingenious tax was introduced, called the "Cure of Petients," which ordained that whenever a surgeon or barber received upwards of £10 for the curing of a patient he should pay 10s. to the funds of the calling. The sum realized in this way in one year amounted to £23 10s. Another way of helping the funds to a certain extent was by fees charged for the loan of a mortcloth or funeral pall, which was hired out at interments for the purpose of covering the coffin. The incorporation apparently possessed two of these mortcloths, one of which had armorial bearings worked upon it, and the other, which cost £175 2s., was made of velvet.

The Surgeon-Apothecaries.

Both the internal economy and the external circumstances of the incorporation were subject to great stress in the early days. The surgeons were constantly attempting to dissociate themselves from the simple barbers. At the same time new drugs were being imported and pharmacy was becoming a recognized art, so that the treatment of patients was passing to a considerable extent into the hands of men who dealt in drugs. From 1657 the character of the incorporation underwent an important change. Several of the more outstanding barber-surgeons had become skilled in pharmacy, which was taught to their apprentices along with the art of surgery. The barber-surgeons jealously watched the progress of the apothecaries, ready to hale before the town council any apothecary who was reckless enough to bleed a patient, apply a cerecloth to a dead body, or perform any manual operation. The apothecaries in some instances evaded the consequences by sending accounts to their patients in which no specified charge was made for such services, to the great annoyance of the surgeons. In 1680 a serious dispute arose on this matter between the surgeons and the apothecaries, which was in due course decided by a full bench of judges, who, in the end, found for the apothecaries that the two callings of surgery and pharmacy were no longer to be practised by one and the same person. Partly, no doubt, as a result of the disagreements between the surgeons and apothecaries, the physicians of Edinburgh sought to obtain a charter erecting them into a Royal College, which they effected successfully in 1681.

The book contains much subsequent history regarding the social and domestic activities of the College of Surgeons, the teaching of anatomy, the early association of the incorporation with the Royal Infirmary, the professors of surgery appointed by the Royal College of Surgeons, and the association of the College with the town council. The matters dealt with in these chapters, though of less general interest, are of great historic importance to the Edinburgh Medical School.

HERBERT JONES TESTIMONIAL.

As we announced nearly two months ago, the Herefordshire Medical Society has inaugurated a fund to present a testimonial to Dr. Herbert Jones, who has resigned his appointment as medical officer of health for the combined districts of the county, which he has held for many years, during which he has maintained the pleasantest relations with the medical profession in the area. He has, moreover, done much work for the profession outside the county, both through the British Medical Association and through the Society of Medical Officers of Health. He was a member of the Central Council of the British Medical Association for two terms, and also of its Public Health Committee. He was president of the Society of Medical Officers of Health in 1914-15, and has been a member of its council since 1900. As we stated when first calling attention to the fund (on March 20th), there are few men more intimately acquainted with the intricacies of public health law and its administration, and Dr. Herbert Jones has always been ready to place his knowledge at the disposal of inquirers. For this reason we very heartily endorse the observation Dr. Steed, the honorary treasurer, makes in a letter sending us the second list of subscribers; he says that "the testimonial is worthy of more support from the general body of the profession than it is receiving." We also agree with Dr. Herbert Peck of Chesterfield in his letter published on April 17th, where he

says that those who belong to the public health services should welcome the opportunity of testifying their admiration for Dr. Herbert Jones, and that this applies especially perhaps to the younger members, who, if they now enjoy better salaries than in the past, owe it largely to the efforts of Dr. Jones and others, who in but few instances reaped any benefit for themselves. As Dr. Cox has observed in his recent monthly letter to the officers of the home Divisions and Branches and to members of the Council and central committees, the fund should appeal to workers of the Association, because Dr. Jones was one of the pioneers in bringing about better relations between the public health service and the general practitioner. Dr. Jones, who has been for some time in very bad health, has always held one of those posts in the public health service which is very modestly remunerated. Those who know the circumstances best feel that the fund should be a substantial testimony to Dr. Herbert Jones's fine work. Subscriptions should be sent to the honorary treasurer of the fund, Dr. John Steed, Staunton-on-Wye, Hereford.

SECOND LIST OF SUBSCRIBERS.

- £5 5s.—Dr. J. D. Jenkins (Ystrad Rhondda), *Sir George Newman, K.C.B.
 £5.—Dr. J. C. Thresh.
 £2 2s.—Dr. J. R. Bulman (Hereford), *Dr. W. F. Cornfield, Professor H. R. Kenwood, C.M.G. (Stoke Newington), *Dr. A. B. McIlister, Dr. R. Priehard (Cardiff), *Sir John Robertson, C.M.G., Dr. G. Clark Trotter (London), Dr. Meredith Young (Chester).
 £1 1s.—*Surgeon Captain G. W. Andrews, C.B.E., R.N., *Dr. E. G. Annis, *Dr. G. A. Auden (Birmingham), *Dr. T. W. Barlow, O.B.E., Dr. J. Blackett (Bath), Dr. S. Child (Horsham), *Dr. R. Ashleigh Clerge, Dr. J. M. Clements (Beckenham), Dr. Alfred Cox, O.B.E. (Medical Secretary, British Medical Association), Dr. G. J. Cressy (Leominster), Dr. J. Neville Croge (Worcester), *Dr. W. F. Dearden, Dr. L. A. Drake (Doncaster), Dr. H. E. Durham (Hereford), Dr. R. F. Garrow (Chesterfield), *Dr. Nicholas (Wimbledon), *Dr. W. L. M. Goldie, O.B.E., *T. I. Walker Hall (Bristol), Professor T. Eustace C. W. Hutt (London), *Professor H. Kerr, Dr. Ian W. Macgregor (Hereford), *Dr. T. S. Millard, Dr. Thomas Orr (Ealing), Dr. George Parker (Cardiff), Dr. H. B. Pope (Hereford), Dr. A. E. Porter (Reigate), *Dr. A. M. N. Pringle, *Dr. T. Rhind, Dr. C. Sanders (Carshalton), Dr. R. T. Slingar (Worcester), *Dr. J. V. A. Sumpson, Dr. J. Lionel Stietton (Kidderminster), Dr. G. D. Tullis (Hereford), *Dr. H. Gibbins Ward, Dr. A. M. Watts (Broadstairs), Dr. A. I. W. Wilkinson, *Sir Dawson Williams, C.B.E. (Jocynna), *Dr. E. Colson Williams, Dr. Rol (Jocynna), *Dr. J. B. Yeoman (Birkenhead), and the fol Rhondda (through Dr. J. D. Jenkins): Mr. Llywelyn, Mr. G. Reed, Mr. O. Thomas, Dr. W. E. Thomas, Mr. J. Williams.
 £1.—*Dr. W. D. Carruthers, Dr. T. F. Dewar, C.B.
 10s. 6d.—*Dr. J. P. Litt, Dr. A. Murphy (Brynmenai).
 *Through the Editor of *The Medical Officer*.

ROYAL MEDICAL BENEVOLENT FUND.

At the last meeting of the Committee fifty-three cases were considered and £548 voted to forty applicants. The following is a summary of some of the cases relieved.

Daughter, aged 56, of M.R.C.S. (Bart's) who died in 1889. Was in a home for several years, but latterly has been able to take light posts, and having had to leave her last employment through ill health, an emergency grant of £1 was given to tide her over. She has now secured another post.

Daughter, aged 32, of M.D. Dub. who was in the navy and died in 1897; he had retired and commuted his pension three years before he died. All money invested in Germany was lost in the war. Applicant has supported herself and her mother, but owing to recent ill health has not been able to earn enough. An emergency grant of £2 10s. was given. The applicant is a B.A. and is at present seeking some light post as her health is indifferent.

Widow, aged 94, of M.R.C.S. who died in 1867. Up to the age of 75 she supported herself by taking lodgers. She has made her home with friends for the last twenty years, but now is so old and feeble that she requires constant attention. She has the old age pension and £20 from a charity, and the Fund was asked to supplement this to enable her to have an attendant. Rent 10s. a week. Voted £40 in twelve monthly instalments.

Daughter, aged 66, of a practitioner who died in 1875. She and her sister, aged 61, have managed to maintain themselves, but owing to illness and ill health are now without money for necessities. The applicant has managed to earn her living as a hosiery machinist until recently, and now receives 9s. a week (disability benefit). Her sister is present is very ill in hospital. Voted £12 in twelve monthly instalments. The application for a grant for the sister will be considered later.

Daughter, aged 74, of M.R.C.S. Eng. who died in 1876. She had a school for thirty-five years, but has had to sell it in order to refund money to the estate of her late partner. She has the old age pension. The Fund voted £30 in twelve monthly instalments.

Subscriptions may be sent to the Treasurer, Sir Charles Symonds, K.B.E., M.S., at 11, Chandos Street, Cavendish Square, London, W.1.

The Royal Medical Benevolent Fund Guild still receives many applications for clothing, especially for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles. The gifts should be sent to the Secretary of the Guild, 58, Great Marlborough Street, W.1.

British Medical Journal.

SATURDAYS, MAY 8TH AND 15TH, 1926.

THE USES OF VACCINES.

OUR knowledge of the prophylactic uses of vaccines is, for reasons which are easily discovered, much more accurate than our knowledge of their therapeutic uses. To judge of the efficacy of any remedy for the prevention of disease is a relatively simple matter. The experiment is a clean one, free from complications. The patient will or will not catch the disease against which we seek to protect him, and if a sufficient number of experiments can be performed the statistician can pronounce his judgement confidently. But to judge of the efficacy of any remedy to be used in the treatment of disease is a much more difficult business, because the issues are more complicated. With many diseases recovery is the rule, and in all the impartial observer must admit that several agencies may have co-operated in the cure. It is natural, therefore, that our knowledge of vaccine prophylaxis should be richer than that of vaccine treatment, and it is easy to give examples. Thus, when employing vaccines for prophylaxis, as with the typhoid vaccine, we can speak confidently of the number of million microbes necessary, and we can foretell with reasonable precision what may be expected from this dose. We also know the length of time the immunity is likely to last. Compared with this accuracy of knowledge the treatment of existing disease by vaccines is mere guesswork. There is plenty of evidence that vaccines are useful in the treatment of many different infections, but the time for their administration, the interval between the injections, and even the size of the dose, are questions on which widely different opinions are held. The principles of the method of giving vaccines in the treatment of disease are not properly understood, and the details of technique are not based upon experimental evidence, but are decided at the discretion of the clinician.

Professor Ledingham has pointed out in the lecture we publish to-day (p. 815) that much of what is commonly called vaccine therapy is really vaccine prophylaxis. The vaccine treatment of furunculosis, for instance, is largely, if not wholly, a question of prophylaxis; for immediate benefit is not considered the chief aim, but rather a response in the tissues which will secure a greater immunity in the future. But in spite of the fact that much of what is called vaccine therapy may be moved to the firmer foundation of vaccine prophylaxis, there remains a definite small residue which belongs to treatment and not to prevention. Professor Ledingham considers that what is not prophylaxis is simply an example of non-specific protein therapy. There is certainly a lack of strict specificity about the results obtained, and the clinical manifestations appear too soon for them to be attributed to the much more slowly moving machinery known to operate in prophylaxis. Sufficient evidence has now accumulated to show that in many diseases it does not much matter what bacterial protein is given in the vaccine. Such a dose of vaccine may act,

as Professor Ledingham suggests, by causing a greater flow of blood through some indolent inflammatory focus, or it may act in some entirely different way, calling into play a mechanism with which we are not familiar.

To return once more to the securer territory of vaccine prophylaxis, it is satisfactory to find that we are able to form a fairly clear mental picture of what is aimed at when a vaccine is given to prevent disease. A certain amount of confusion clouded the picture when pathologists began to insist that immunity to disease does not run parallel with, and cannot be measured by, such easily demonstrable antibodies as agglutinins, opsonins, precipitins, etc. But there is one reliable method of measuring immunity in experimental animals, and that is by estimating the increased capacity to stand a lethal dose of the particular germ. We can apply the knowledge gained from this experimental work to the problem of human disease, and say that the real aim of immunization is to produce that alert state when all the defensive machinery of the body can be mobilized at the earliest signal, and the circulating fluids at once saturated with protective antibodies. It is this state of preparedness which vaccine prophylaxis aims to produce.

THE BIOLOGY OF POPULATION GROWTH.

DR. RAYMOND PEARL is well known to English students as a brilliant pupil of the school of Karl Pearson who has done more than any other investigator and teacher to make available in America the methods of research which two great Englishmen—Francis Galton and Karl Pearson—created. Dr. Pearl began his scientific career as a biologist; he was afterwards an eminently successful university professor of vital statistics and biometry; he has now, well armed with statistical methods, formally rejoined the biological army, or the general staff of that army, and directs an institute of biological research.

His latest volume,¹ although it could only have been composed by a trained statistician, expounds the point of view of a philosophical biologist. He begins by showing how various forms of growth, from that of individual rats to populations of men, can be described by a simple curve tending to an upper and a lower limit. He then shows that in an experimental microcosm of flies the growth of population follows the same course as that of a nation of men living under the conditions of modern civilization. Then he shows that if we pass from civilized to semi-civilized races, from the French to the indigenous population of Algeria, we again find this curve. There follows an extremely interesting and well written account of the history of modern Algeria. Clearly the indigenous population does not resort to contraceptive measures in any natural sense of the term, yet the birth rate falls. Why? Evidence is then presented indicating that increasing density of population is associated with decreasing fertility, as Michael Thomas Sadler thought he had demonstrated ninety-five years ago. Dr. Pearl does not refer to Sadler, who was a poor statistician and a worse writer, no match for that master of the eocksure school, Macaulay. Yet Sadler was not so far wrong at bottom, and was by no means so ridiculous as his political opponent supposed.

Dr. Pearl then passes to a discussion of the differential birth rate, and remarks—justly, we think—that

¹ *The Biology of Population Growth*. By Raymond Pearl. New York: Alfred A. Knopf. 1925. (5½ x 8½, pp. xiv + 260; 41 figures. 3 dollars 50 cents net.)

"the efforts of the eugenists to correct the evils of the differential birth rate by endeavouring to induce the socially, economically, and in some part biologically superior classes to reproduce more freely, as a sort of transcendental social duty, have not met with any discernible success, and in my opinion are not likely to." He comes down decisively on the side of the advocates of birth control: "But if it is not possible to make desirable people have more babies, why not try teaching other people how to have fewer? This is precisely the position of the birth control movement, and it seems to me to offer the only hope of altering for the better the existing differential inequalities in the distribution of the birth rate." An elaborate statistical analysis follows of some data regarding the frequency of sexual intercourse in the married life of a sample of men who had been successfully operated on for the relief of benign hypertrophy of the prostate; but the bearing of this upon the general theme of the book is, perhaps, a little remote.

Lastly, Dr. Pearl summarizes the deductions he thinks warranted by the evidence. He considers it to be established that there is an "inexorable" law of population growth, but he is less pessimistic than Malthus as to the consequences. On this point he writes: "I think the thing which first made me dubious about this inevitable misery doctrine was its seemingly compelling logic. It was so easy to prove logically that it must be so that I began to be suspicious that in fact it probably was not so at all. Long experience with experimental work has taught me that a somewhat rough and ready, but on the whole dependable, rule is that any natural phenomenon which, in advance of observation of the event, can be proved by purely logical processes to be necessarily so, almost invariably turns out upon really competent and penetrating trial or observation to be in fact not so at all but quite otherwise. This curious phenomenon is, of course, not the fault of logical processes of thought, but merely an expression of human fallibility in the matter of premisses."

The subject of this inquiry is one of much medico-sociological importance, and Dr. Pearl handles his material with skill and discretion. Those familiar with the author's scientific writings will recognize various results which have been published in other forms, but even they will find a great deal of fresh matter, and an educated man who does not know the "literature" could hardly choose a better introduction to the problem of population.

"BRITISH MEDICAL JOURNAL."

THE present issue of the BRITISH MEDICAL JOURNAL, was in course of preparation for printing last week, and should have been published on Friday, May 7th, with the date "May 8th, 1926." The general strike, however, stopped all work at the machine printers' office on May 4th. Accordingly publication of the JOURNAL, in common with that of other weekly periodicals, had to be suspended, and no printing could be carried on. The calling off of the general strike on May 12th was not immediately followed by resumption of work at the machine printers' office, but we hope that before the end of this week all copies will have been printed and dispatched. In the time available there is, of course, no possibility of preparing and printing a separate issue for the current week, and it has therefore been decided to revise the contents up to the hour of going to press, and to let this JOURNAL bear the two dates "May 8th and May 15th."

THE LIGHTING OF SCHOOLS.

SHORTLY before the war the Illuminating Engineering Society appointed a committee to report on the lighting of schools. So far as daylight arrangements are concerned the recommendations made by that committee still hold good. The minimum permissible illumination of a school place was defined as 1 per cent. of the outside window-sill illumination. With regard to artificial lighting, however, there seems reason to suppose that the minimum laid down thirteen years ago—namely, two foot-candles for any school place—is much too low. At a meeting of the Illuminating Engineering Society on April 29th Dr. James Kerr, late school medical officer for London, in opening a discussion on the subject, said that although he was a member of the committee which had recommended the two foot-candles minimum, further experience of children's vision had brought him to the opinion that this minimum ought at least to be doubled. The better course, he thought, would be to lay down an optimum rather than a minimum. For classrooms this should be an evenly diffused lighting of from five to seven foot-candles on each desk, the light to be given from large "luminaires" (bowls or globes diffusing the brilliance of the original source) of an intrinsic brightness equal to three candles for each square inch of their surface. A child, said Dr. Kerr, could do his work at illuminations below this limit, but it entailed an improper degree of effort. Some regard had to be paid to the psychology of the child. Actual school observations had shown that the young child had to make a considerable effort to recognize the objects which were presented to him. An adult was able to perceive the form of an object or the significance of a word at a glance; the merest hint was sufficient, through the force of association, to enable him to identify it. But the child had to piece the details together or laboriously to spell the word, and therefore well illuminated detail was a need of, at all events, primary education. Another consideration was that the ordinary testing of the vision of school children showed that during the first half of school life about one-third failed to attain the normal standards, and that 10 per cent. of children left the primary schools permanently short-sighted. It was necessary, therefore, to make a considerable allowance for subnormal vision. It was the same with the exercise of the organ of vision as with any other voluntary function of the body; while efforts could be made successfully to work for a short time at "full load," the normal working capacity fell far short of this. The child should not be expected to work continuously in school anywhere near the limits of visual efficiency. During recent years the means of illumination have become greater and relatively cheaper. The gas-filled (half-watt) lamp had been introduced, and there had been improvements in bowls, globes, and reflectors. A smooth and agreeable illumination from a large even source was now possible. All naked sources in schools should be shaded or screened, but while indirect lighting (that is, with the source entirely concealed) must perhaps be left out of account so far as schools were concerned, he thought there was very little preference from the hygienic point of view between direct and semi-indirect lighting. With direct lighting the provision of large globes or shades bringing down the intensity to about three candles for each square inch of the luminous surface made the distribution fairly even, and did away with the main objection to this form of lighting. For myopic children it might be well to use with the lamp certain large daylight or "rest-light" filters. After a proper system of lighting in schools was established it was necessary to maintain its efficiency, and Dr. Kerr expressed the opinion that this matter should not be entrusted entirely to the schoolkeeper; large education authorities should appoint illumination inspectors. With regard to blackboards, the original report of the

committee, which Dr. Kerr again endorsed, was that blackboards should have at least 60 per cent. more illumination than the rest of the room; but on this point one of the subsequent speakers said that there was a limit beyond which a blackboard could not be satisfactorily illuminated because a higher illumination would give a haze over its surface. Many speakers, mostly lighting engineers, took part in the discussion, but their contributions added little to the stock of practical experience in school lighting. One point brought out was the value of left-hand light balance, in which the lamps in a classroom are placed a few feet away from the wall on the pupils' left, the reflective power of the wall being utilized to give an even illumination over the left shoulder. The chairman of the meeting, Dr. E. H. Nash, took occasion to observe that it might be all very well to talk of five, seven, or ten foot-candles on the desk, of the possible introduction of indirect lighting for schools, and of the appointment of special mechanics to superintend the lighting, but financial economy was a very stubborn factor which had to be reckoned with by education authorities and those who advised them.

THE MACHINE AND THE MAN.

An interesting report to the Industrial Fatigue Research Board on the design of machinery in relation to the operator has been issued by the Medical Research Council. From time to time note has been made of damage done to workers through the defective construction of machines; the incidence of Dupuytren's contraction in lace-winders is an example; it has been shown to be related to the size and shape of the levers on lace machines. But the Industrial Fatigue Research Board could not find that any systematic research into the subject had been made. It was proposed, therefore, that a special committee should be appointed to investigate; and the Board advised the Medical Research Council that the Department of Scientific and Industrial Research should be asked to co-operate. A committee of six members was formed, and Professor E. H. Starling was made chairman. The mechanical side of the investigation was entrusted to two engineers, Mr. L. A. Legros and Mr. H. C. Weston, and on the physiological side Professor E. P. Cathcart of Glasgow has been supervising the necessary research. The investigation was started on two lines: (1) a general survey of repetitive machines, in order to disclose any defects in design; (2) physiological research into the energetics of muscle, especially in the movements employed in machine control, in order to determine the limits in which they can be exercised under favourable conditions. The report now issued is by Legros and Weston, and deals with the first line of investigation; its study by machine manufacturers will, it is hoped, secure their collaboration. Machines in common use are described in which the design appears capable of improvement. Physiological research presents such formidable difficulties in apparatus and technique that a long time must elapse before any results of practical applicability can be obtained. In an introduction to the report the difficulties in the evolution of a machine that attains its object with a minimum of discomfort and fatigue to the operator are illustrated by the story of the bicycle—the two-wheeled frame with a saddle, invented in France in 1818, through the “hobby-horse” of 1840, the “boneshaker” of the sixties, the “ordinary” of the youth of some of us, with its instability fore and aft, and the short-lived “kangaroo,” to the rear-driven safety invented in 1879. A period of fifty years was occupied in increasing mechanical efficiency to practically the present figure; there followed a second period in which the human element was recognized as part of the machine,

and improvements were made in safety, in lessened vibration, and in increased power in speed and hill-climbing with lessened fatigue. The improvements have met the requirements of the rider physiologically by reducing vibration and lessening fatigue, and psychologically by diminishing the risk of accident. The neglect of the user's interests in other machines may, as the authors suggest, cause unnecessary fatigue accompanied by loss of output. In the report investigations are recorded from this point of view into laundry machines, leather-working machines, and some miscellaneous machines, such as those used for boring, boots and shoes, textile work, and tobacco-cutting. Legros and Weston have been able to point out improvements and modifications which could be carried out without great expenditure. They quote in their report some remarkable incidents in time-saving introduced by Henry Ford through attention to the comfortable position of the men while at work. Incidentally, it is noted how readily the workmen—and the designers—become slaves to habit, so that often alterations in method are opposed by the workmen themselves.

THE ISOLATION AND CONSTITUTION OF INSULIN.

A FEW weeks ago (April 10th, p. 666) a short account was given of a communication published by Professor J. J. Abel of Johns Hopkins University, who has been engaged for some time on the preparation of highly concentrated insulin, in which he stated that he had succeeded in obtaining a crystalline compound with an activity of about 100-rabbit units per milligram. Parallel researches on insulin have been conducted by Professor Casimir Funk in Warsaw, who published a preliminary communication in January this year (*Proc. Soc. Exper. Biol. and Med.*, 23, 281, 1926). In a further note (*Science*, lxiii, 401, 1926) he has announced that the probable formula for insulin is $C_{27}H_{45}O_{12}N_3S$, with a molecular weight of 1565. He believes the structure of the compound to be a polypeptide composed of fifteen amino-acids. The convulsive dose for rabbits of pure insulin obtained in this way is about 0.08 mg. The chief conclusions of Funk and Abel appear to be in fair agreement, for both find that pure insulin is a sulphur-containing compound composed of amino-acids. The two observers also find activities for their final preparations to be of the same order. These investigations appear to prove that insulin is one of the most potent substances known, and it will be interesting to see if further research confirms the conclusions arrived at regarding its crystalline structure and molecular weight.

THE ROYAL SOCIETY.

EIGHT distinguished men of science have lately been elected foreign members of the Royal Society; the last similar election was held in 1921. Professor Martinus Willem Beijerinck, of Gorrssel, Holland, is one of the leading authorities on the physiology of bacteria, and the author of 129 publications on researches into bacteriological and vegetable physiology. Dr. Niels Bohr, professor of physics, Copenhagen University, is the director of the Spectroscopical Institute and the founder of the modern theory of the relation between spectroscopy and atomic structure. Dr. Ernst Cohen, professor of physiology and general chemistry at Utrecht, is a director of the Van't Hoff Laboratory also, and has conducted many researches into the allotropic states of the chemical elements, and the conditions of stability of pure substances in the solid (crystalline) state. Dr. Willem Einthoven, professor of physiology, Leyden, is well known for his ingenious work in devising instruments for recording minute electrical changes in animal and plant tissues, as well as many instruments for other researches in physiology and physics. Dr. Karl Ritter von Goebel of Munich has published numerous investiga-

tions dealing with vegetable morphology. Professor Henry Fairfield Osborn of Columbia University, New York, is director of the American Museum of Natural History; his work on the evolution of mammalian teeth is well known, and he has also published numerous articles on the horse, rhinoceros, and dinosaurs and other prehistoric animals. Professor Max Planck (Berlin) is distinguished for his studies in mathematics and physics, and was the founder of the quantum theory. Professor Arnold Sommerfeld of Munich is also a well known mathematician and physicist.

THE WORK OF THE ROCKEFELLER HEALTH BOARD.

THE annual report for 1924 of the Rockefeller Foundation's International Health Board has just been issued. It has been prepared by the general director, Dr. F. F. Russell, and is the eleventh of the series. During the year the Board co-operated with the Government health agencies of ninety States and countries in their efforts to improve the health and general well-being of their populations. Public health activities may be divided into two main categories—in the first place, improvement of environment, such as sanitary conditions, guarding of water supply, and clean food; and secondly, the measures dealing directly with individuals, such as medical inspection of school children, infant hygiene, pre-natal and maternity services. In many countries the outstanding need is improvement of environmental conditions; in tropical and subtropical regions soil pollution is a most important factor in hookworm disease, and against it the International Health Board has for years conducted a well organized campaign which has done a great deal to control the widespread scourge, though much remains to be done; the problem is said to be serious in India; it is estimated that in the Madras Presidency 70 per cent. of the population of 45 millions are infected. It is perhaps inevitable, but certainly disappointing, that, after having been clear since 1922, Salvador had a flare-up of yellow fever in June, 1924; preparations were being made to attack early in 1925 the last stronghold of yellow fever in West Africa. The results of the antimalarial campaign are encouraging; Yazoo County, Mississippi, is an example, for the incidence of malaria there has fallen since 1920 from 126 to 32 per 1,000. Valuable work on the determination of the special varieties of mosquitos conveying malarial infection in different countries has been undertaken. Education of both Government officials and the public plays a prominent part in the campaign against disease, and an epidemiological intelligence department is being maintained.

CANCER COMMISSION OF HARVARD UNIVERSITY.

THE thirteenth annual report of the Collis P. Huntington Memorial Hospital for Cancer Research and of the laboratories of the Cancer Commission of Harvard University has just been issued; it covers the year ending June 30th, 1925. The hospital and laboratories have both been in active operation throughout the year, and the number of new patients is steadily increasing. It is likely that the pressure on this special hospital will be relieved in the near future, for the report mentions that two other clinics for cancer patients will shortly be available. One of these, an out-patient "consultation tumour clinic," is in fact already in operation at the Massachusetts General Hospital, with an attendance of about 150 cases a month. The other is to be an additional cancer hospital equipped with all resources for treatment and research. To both of these projects the Huntington Hospital has given assistance and support on the ground that greater facilities are needed than those now available for the treatment of cancer, and that the withdrawal of some of the routine cases from the Huntington clinic would make possible a greater selection of material suitable for investigation. The report is con-

piled on the same plan as its predecessors, and contains reviews of the year's activities by the chairman, director, chief physician and surgeon, matron, social service worker, research workers, State diagnosis service, and treasurer. A brief account is included of research work carried out in the departments of physics, pathology, and clinical medicine, and a list is given of the 186 papers contributed to scientific papers by the staff during the year.

PROTOZOAL PARASITES.

Protozoology, like so many of the scientific handmaidens of medicine, is a child of lowly birth and humble upbringing, which has now reached a sturdy and healthy adolescence—a fact brought to mind by the recent publication of a short history of the subject by Professor F. J. Cole.¹ Although Leeuwenhoek, the father of protozoology, wrote as long ago as 1675, it was not until a century and a half later that the subject received more than the casual attention of a handful of distinguished observers. The first human protozoal parasite—the amoeba of the mouth—was not found until 1849; but during the nineteenth century the science progressed rapidly, and, so far as man is concerned, reached its high-water mark with the discovery of the life-history of malaria—that everlasting monument to the intuitive genius of Manson. This, however, was only the last of a series of discoveries, often on apparently unrelated branches of the science. In 1878 Manson discovered the life-history of *Filaria bancrofti* in the mosquito; in 1893 Smith and Kilborne showed that the protozoan parasite of Texas fever was tick-borne; in 1896 Bruce showed the connexion between the tsetse and the trypanosomes of animals; and in 1898 Ross published his work on the transmission of bird malaria by grey mosquitos. These were the milestones which lead up to the solutions of the problems of malaria and sleeping sickness. In one respect there is an interesting parallel between the histories of these diseases; in both cases the life-history was first of all established in an animal species, and the knowledge so gained was afterwards applied to detect the cause of a human disease. Professor Cole's history, however, is not mainly concerned with the medical or even the economic aspect. He ranges over the whole subject—and it is a wide range—drawing a lesson here and pointing a moral there. He illustrates not only the importance of success, but the significance of failure. "The secrets of this inscrutable cosmos yield themselves only to the few; the work is difficult, mistakes are inevitable, and progress slow." In criticizing our predecessors we must remember that we stand on their shoulders, and we owe as much to their mistakes as to their wisdom. Nevertheless, all the striving and controversy only serves to invigorate that regard for faithful observation on which all serious research must in the last resort depend. Professor Cole's history is necessarily brief, and he has been able to paint only the high lights on a canvas full of colour and varied form. But he has in the few pages at his disposal written an essay full of interest to all, and pregnant with sound understanding of the pitfalls which beset the scientific historian.

A FRENCH VIEW OF MARRIAGE AND SYPHILIS.

THE meeting of the Medical Society for the Study of Venereal Diseases on April 30th was addressed by Dr. G. Lacapère, consulting physician to the St. Lazare Hospital, Paris, formerly of the St. Louis Hospital, and a pupil of the late Professor Fournier. The subject of Dr. Lacapère's address was syphilis and marriage, and he discussed the conditions under which medical men in France considered themselves justified in permitting the marriage of a person who had had syphilis. Absolute proof of the eradication of

¹ *The History of Protozoology*. By F. J. Cole, D.Sc., Oxon. London: The University of London Press, Ltd. 1925. (Demy 8vo, pp. 67; 2 plates. 3s. net.)

the disease could not be established with regard to syphilis any more than with regard to tuberculous and other chronic infections. The fact that the Wassermann test became negative did not give absolute security. Syphilis, following the general pathological law, was more likely to be cured the earlier treatment was started. During the fifteen or twenty days after the appearance of a chancre the reaction was negative, the syphilis remaining local; the cure during this period was consequently easy. It was easier still if, within a week or two weeks after a dangerous contact, preventive treatment could be started in the shape of injections of "914." After such a patient had been under clinical and serological observation for a year following this course of preventive treatment, and everything remained normal, permission to marry might be given. If treatment was not started until after an unquestionable primary sore had developed, intravenous injections of arsenobenzol should be given, a first series rapidly, and a second series three weeks after the last injection of the first. This might be followed up by a third series, or by two series of injections of insoluble bismuth. The total duration of the treatment should be about ten or twelve months, after which an observation period of from eight to twelve months was necessary. If the reaction then remained negative, if a provocative injection of "914" gave satisfactory results, and if the cerebro-spinal fluid was normal, the patient might be allowed to marry. In cases in which a positive reaction had already developed, almost all French syphilologists used the "914" preparation, some advising intravenous injections and others intramuscular. Dr. Lacapère preferred intravenous injections when attacking syphilis in the stage before a positive reaction had appeared, but after the appearance of the positive reaction he frequently had recourse to intramuscular injections, though he considered these effective only if the doses given were equal to those administered by the intravenous method. The intramuscular injection of "914," however, was not always well borne, and sometimes he used injections of sulfarsenol alternating with insoluble bismuth injections, so permitting the sulfarsenol to be brought down to a point evoking only a mild degree of pain. His practice was to give once a week an intramuscular injection of sulfarsenol and, three days later, an intramuscular injection of bismuth. Two and sometimes more series were necessary, an interval of three or four weeks separating the series. This regular treatment should be continued for some time, even if the tests were negative. Treatment for eighteen months was the minimum, and after the tests became negative it was advisable to continue the injections for a year. As long as the tests were still positive he used "914" injections alone, or combined with bismuth injections; when the tests became negative he gave for a year treatment with insoluble bismuth. If everything remained normal a provocative injection was given and a lumbar puncture made, and then, if all tests were negative, marriage might be authorized; but a minimum of two and a half years should elapse from the commencement of treatment. Dr. Lacapère also discussed the various indications for the treatment of syphilis in the tertiary stage. If no irremediable symptoms, such as angina pectoris or tabes, manifested themselves, the practitioner should set himself to cure the actual symptoms and render negative the tests of the blood and spinal fluid, continuing the treatment long enough to avoid relapse, and keeping the patient under observation by tests at regular intervals and provocative injections. In spite of all precautions it might happen that syphilis was transmitted to the children of the marriage, and most French syphilologists advised an intensive treatment during the weeks preceding marriage. The precautions to be taken must be greater in the case of a woman than of a man. If a woman had had syphilis, although the reactions might have been negative for years,

the result might still show itself in miscarriages or infected children. It was therefore advisable, unless the cure of the syphilis dated back for a very long time—at least eight years, according to one French authority—that the woman should take a course of treatment during pregnancy. In the treatment of the expectant mother arsenobenzol given by intravenous or intramuscular injection seemed to furnish the best results. His own frequent plan was to give a series of "914" injections, with intervals of six weeks, during which he gave biweekly injections of insoluble bismuth, the treatment being continued until three weeks before confinement.

THE CASE OF DR. KNOCK.

Dr. KNOCK's first activities on taking over a small country practice from Dr. Parpalaid were to summon the town crier and arrange for his services, meet the schoolmaster and suggest that lectures on hygiene should be instituted, come to a satisfactory business arrangement with the chemist, and finally give free consultations on Monday mornings from 9.30 to 11.30. The results were eminently satisfactory to him, and the number of patients seen weekly rose from about 10 to 150, and the number of patients under regular treatment at home from almost *nil* to over 200 each week. Dr. Knock spent the first month in finding out the incomes of each of the six thousand inhabitants of the village, for, as he argued, each inhabitant was *ipso facto* a potential patient, and he wished to be quite clear as to the quality and quantity of treatment which might be ordered for a specific case. The question whether such conduct is to be regarded as infamous in a professional respect fortunately does not arise, for the village is Saint-Maurice in France, and although portions of it are represented on the stage at the Royalty Theatre, London, it is doubtful whether Dr. Knock, in the person of Mr. Dennis Eadie, will be dealt with by any disciplinary body. Dr. Knock had spent his very earliest years in a close study of the advertisements of patent medicines, and thus equipped he secured a post at the age of 20 as "ship surgeon, partly qualified," after he had taken a university degree in ancient history and made a living by the sale of shirts. Following a very successful voyage in which no patient died—for Dr. Knock does "not approve of patients dying"—he traded in monkey-nuts for some years, but, becoming bored with this and with many other pursuits, he studied medicine, and obtained his M.D. with a thesis entitled "The common misuse of the word 'cure' in medicine." Dr. Knock professes that he serves the cause of medical science, and seeks to resolve each inhabitant of the village "into a medical existence of his own." He boasts that he will put the whole town to bed if necessary, and when the final curtain falls on this clever satire by Jules Romains, translated by Harley Granville-Barker, it seems extremely probable that he will carry out his threat. A note on the play as originally performed two years ago in Paris was published in our issue of January 26th, 1924 (p. 178).

At the forthcoming Eucanla the University of Oxford will confer the honorary degree of D.C.L. on Lord Dawson of Penn, and that of D.Sc. on Sir Walter M. Fletcher.

It is with deep regret that we have to announce the death of Mr. Stephen Paget, F.R.C.S., which took place on May 8th at his home in Jimpsfield after a long illness. We hope to publish an obituary notice in our next issue.

On the afternoon of Friday, May 28th, the Prince of Wales will open the obstetric hospital and the nurses' home presented to University College Hospital by the Rockefeller Foundation, and the reconstructed ear, nose, and throat hospital presented by Mr. Geoffrey Duveen.

Canada.

[FROM OUR SPECIAL CORRESPONDENT.]

POST-GRADUATE INSTRUCTION.

THE plans for extramural post-graduate instruction under the grant from the Sun Life Insurance Company are working very smoothly and with great satisfaction. The announcement was made to the annual meeting of the Canadian Medical Association at Regina last year (BRITISH MEDICAL JOURNAL, August 1st, 1925, p. 229), the amount of the grant is 30,000 dollars, and the scheme is an extension of one started some years ago by the Committee on Education of the Ontario Medical Association. In Halifax, for example, the extended scheme was initiated at a meeting of the Halifax branch of the Medical Society of Nova Scotia, at which there was a large attendance. Dr. John Stewart presented a number of photographs and skiagrams which he had just received from Sir George T. Beatson of Glasgow, which were of much interest, since they showed the results of operations performed by Lister forty years ago. Dr. Stewart and Sir George Beatson were fellow students at Edinburgh, and both had worked as house-surgeons under Lister. The illustrations were of a case of multiple tuberculous lesions, in which, amongst operative procedures, Lister had removed the left patella and had united the femur, tibia, and fibula with a single silver wire suture. The man had recently been admitted to the Cancer Hospital, Glasgow, for a malignant tumour of the eyelid, and it had therefore been possible to get the pictures. He had been able to carry on his work as a cattle drover during the intervening years, his knee remaining in a position of complete extension. The wire suture was seen to be intact. The post-graduate lecture for the evening was then given by Dr. J. Appleton Nutter of Montreal, who described certain paralytic deformities, especially those of childhood. These lectures have been delivered in Ontario, where one of the first lectures was given by Dr. A. Primrose of Toronto, and in Manitoba, where Dr. Frank Patch of Montreal and Dr. Duncan Graham of Toronto addressed several branch medical societies.

NOVA SCOTIA AND NEW BRUNSWICK.

There has been an unusual prevalence of diphtheria and scarlet fever throughout various parts of Nova Scotia, but, as has been ascertained by the Department of Public Health, most of the cases of both diseases have been of a mild type. The department also publishes vital statistics which show some interesting comparisons. In August, 1925, for example, the infant mortality rate was 51.1; for August, 1924, it was 104.9. For this month also the tuberculosis death rate was the lowest for a great many months, and the indications are that this rate for the entire year will be the lowest yet recorded. There has been a great improvement in health conditions during recent years, and careful statistical records are brought forward to prove that the greatest gain has been made in districts where public health nurses have been at work for some years.

Similar encouraging reports come from New Brunswick. Dr. H. A. Farris, superintendent of the St. John County Hospital, reports that there has been a decided falling off in the number of cases of tuberculosis in the city of St. John, and the decrease has been most marked in children. It is attributed to the activities of the nurses of the Society for the Prevention of Tuberculosis, and to the work of the County Hospital.

THE CAMPAIGN AGAINST TUBERCULOSIS.

THE National Research Council of Canada last autumn inaugurated extensive plans for a national "campaign" against tuberculosis. There has been no lack of efforts along these lines heretofore, but it was felt that these might be correlated and controlled by a central organization, thus sharing all the benefits of concentration. Data had been collected throughout the previous summer on all the branches of research in tuberculosis—human, bovine, and avian—and in the autumn a meeting of the most prominent men in this field was held in Ottawa. At it a report

was drawn up which set forth under thirteen headings the whole field of research, and after consideration of this report the National Council decided that it would have enough money out of the vote passed at the last session of Parliament to carry on the work thus laid out. Accordingly, 30,000 dollars has been made available, which it is thought will be enough to cover the expenditure during the remainder of the year. In this connexion Dr. Auguste Pettit, of the Pasteur Institute, member of the Academy of Medicine of France, and secretary to the Biological Society of Paris, has accepted an invitation to take charge of the research work at the University of Montreal.

MCGILL UNIVERSITY NURSERY SCHOOL.

TO the many educational interests of McGill University there has now been added a nursery school. The inception of this is due largely to the financial backing of the Rockefeller Foundation, which has given a grant of 10,000 dollars a year for five years for this purpose. The school is designed to care for about twenty children, ranging between the ages of 2 and 4, and careful observations will be made of their growth and psychological development. About eighteen children have been received at the school during the winter, and the scheme, which at first came in for a certain amount of criticism, is now making good progress.

England and Wales.

PRESENTATION PORTRAIT OF THE LATE SIR SYDNEY RUSSELL-WELLS.

AN interesting ceremony took place at the Dreadnought Hospital (Seamen's Hospital Society), Greenwich, on May 4th, when Sir Humphry Rolleston, Bt., unveiled a presentation portrait of the late Sir Sydney Russell-Wells, M.P., who was assistant physician to the hospital from 1906 to 1908, and physician from 1908 until his sudden and premature death in 1924. Among those present were several relatives of Sir Sydney Russell-Wells, including his brother, Sir William Wells. The portrait, which was painted by Mr. John Wells, R.I., a nephew, is of life-size, three-quarter length, and shows its subject wearing the gown of Vice-Chancellor of London University, while a view of Greenwich appears in the background. Dr. C. E. Sundell, physician to the hospital, in asking Sir Humphry Rolleston to unveil the painting, said that the portrait was a tribute to the memory of a colleague. The idea of the portrait was formulated at a meeting of the medical council of the hospital, and received at once unanimous support. The staff felt that to them a portrait was not a necessary memorial, because they would always have in their minds a recollection of Russell-Wells as a physician, a friend, and a counsellor, but they knew that as time went on, and changes took place in the staff, it was well that there should be a permanent memorial on the walls of the staff room of a man of such outstanding gifts and personality. The name of Sir Humphry Rolleston came at once to mind when they considered who should be asked to perform this ceremony: in the first place, because he was associated with the same hospital (St. George's) as Sir Sydney Russell-Wells; in the second place, because he had held for four years the highest place that a physician in this country could attain—that of President of the Royal College of Physicians; and, finally, because during the war he held high naval rank and served the sailor to whom Sir Sydney Russell-Wells also devoted so many years of labour.

Sir Humphry Rolleston, before unveiling the portrait, referred to the whole-hearted devotion of Sir Sydney Russell-Wells to all aspects of the welfare of the hospital. As a physician he took a wide interest in all forms of disease, in particular diseases of the heart and circulation, which, as they now knew, had a melancholy association with his personal health. He was a man gifted with foresight and imagination. Impressed with the importance of biochemistry, he was anxious that the pathological department of the hospital should be reinforced by the appoint-

ment of a biochemist. Some of his latest work was done on a subcommittee which was concerned with additions to the hospital and the erection of a nurses' home. As a member or chairman of committees he had great abilities; he was clear, conciliatory, and convincing, and a past master of procedure. One closely associated with him in this capacity said: "I have never seen anyone like him as a member of committees; he had a gift of exposition and of marshalling his points which would convert the most determined opponents in an almost uncanny manner." This talent he certainly utilized for the benefit of the Seamen's Hospital in the thorny questions that must needs arise concerning the policy and administration of hospitals. The speaker himself had seen Russell-Wells's steady progress from a student at St. George's (1889) to Vice-Chancellor of London University (1919-22). His success in this high office, in which he succeeded Sir Cooper Perry, was marked by the establishment of a School of Commerce and of a degree in that important aspect of national life. Russell-Wells's services to the University began in 1903, when he became a member of the Senate as a representative of Convocation, being elected by the registered graduates in science. He was vice-chairman of the Council for External Students from 1906 to 1908, when he became chairman, and he guarded their interests and maintained a just balance between the internal and the external students. He was also the representative of the University in the House of Commons and on the General Medical Council. In all these many and varied activities he never spared himself, and there was little doubt that his devotion to duty conduced to his premature death. No ordinary man in mental ability, he had many other sides and interests: he was a prominent Mason, was keenly interested in engineering and electricity as hobbies, and was a skilful craftsman in his workshops, where he loved to spend his leisure time. He had rigorously trained himself, and his success was recognized as his due. They would not look upon his like again. Sir Humphry Rolleston concluded by saying that it was most appropriate that the portrait of Sir Sydney Russell-Wells, due to the generosity of those who knew from intimate association his ideals and the character of his work, should be offered to the hospital which he had served so long and unselfishly. Fortunately the work was entrusted to a most skilful artist who, as his nephew, had special advantages for the execution of this successful portrait of Sir Sydney, which, on behalf of the subscribers, he asked the Seamen's Hospital Society to accept.

Sir Arthur Clarke, chairman of the board of management, accepted the portrait on behalf of the Seamen's Hospital Society, and also paid a tribute to Sir Sydney Russell-Wells. Sir Sydney's gift which he most coveted was his peculiar power of getting people to agree with him. Professor R. Tanner Hewlett, director of pathology at the hospital, in proposing a vote of thanks to Sir Humphry Rolleston, said that his own association with Sir Sydney Russell-Wells dated back for some thirty years. The first time he met him was in the mid-nineties, in a house in Great Russell Street, which was then the headquarters and laboratory of the British Institute of Preventive Medicine, now the Lister Institute. At that time many people supposed that when the body was invaded by micro-organisms it got rid of them by producing some disinfectant substance which killed them off, and he remembered how eagerly Sir Sydney Russell-Wells set himself to search for this substance, thereby illustrating his bent towards biochemistry. Mr. R. E. Bickerton, D.S.O., ophthalmic surgeon to the hospital, seconded the vote of thanks, and recalled that among Sir Sydney Russell-Wells's lovable qualities was a keen sense of humour.

STANDARDIZATION OF HOSPITAL ACCOUNTS.

We have previously referred to the fact that the form of systematization of hospital accounts, first recommended in 1906 by the King Edward's Hospital Fund for London, the Metropolitan Sunday Fund, and the Hospital Saturday Fund, has been found unsuitable for universal application. Sir Basil Mayhew criticized the system severely in his introduction to Mr. Joseph E. Stone's book

on hospital accounts, as we mentioned on September 27th, 1924 (p. 586), and the fourth edition of *The Revised Uniform System of Hospital Accounts*, now issued by the three Funds, contains amendments which go some way to meet the objections which have been raised. The basis of the method advocated by Mr. Stone was that termed "costing," which is well known in every large commercial business, but is difficult of application to hospital accounts. A step towards the adoption of such a procedure is taken in the appendix to this new edition, which deals with the internal control of hospital expenditure, including quantitative statistics of food and other commodities, the periodical compiling of estimates of income and expenditure, and departmental costs with an illustrative departmental analysis on "costing" lines. Although the interdependence of the various hospital departments renders the application of such lines very difficult, yet the removal from this edition of the old requirements which made "costing" more difficult, and the provision of an illustration of how the analysis of departmental expenditure might be made, open the door for such hospitals as wish to work out cost accounts. Without much change in the published accounts the way has been prepared for hospitals to develop an accounting system which would enable them to ascertain the costs of work done in each department. The characteristic feature of *The Revised Uniform System* as a whole is that it provides for the complete separation of the income and expenditure on maintenance account from all other items. The income and expenditure account contains only the items of income and expenditure relevant to the year, but without any exceptions. The ordinary income has now been grouped under three main headings: voluntary gifts, receipts on account of services rendered, and the return from invested property, which are the three main sources of hospital income; the grouping of expenditure has also been simplified. The present edition has been prepared after consultation with the British Hospitals Association, the Incorporated Association of Hospital Officers, and the hospitals on the books of the Fund, by a subcommittee of the Hospital Economy Committee of the King's Fund, under the chairmanship of Sir Basil Mayhew. It is issued with the authority of the three Funds and supersedes all previous editions. It is required to be used by every hospital in London receiving grants from the three Funds; the Voluntary Hospitals Commission of the Ministry of Health has recommended the universal adoption of the system, and restricted its grants to hospitals using it or some other form of accounts approved by the Commission.

NOTIFICATIONS OF INFECTIOUS DISEASE.

We have received from the Ministry of Health the following tabular list of notifications of infectious disease in London and in England and Wales (including London) during the week ending May 1st, 1926:

	London.	England and Wales (including London).
Small-pox ...	—	146
Scarlet fever ...	241	1,518
Diphtheria ...	242	979
Enteric fever ...	9	44
Pneumonia ...	117	1,198
Puerperal fever ...	5	42
Cerebro-spinal fever ...	3	9
Poliomyelitis ...	—	3
Poliomyelo-encephalitis ...	—	2
Encephalitis lethargica ...	4	53
Continued fever ...	2	7
Dysentery ...	—	2
Ophthalmia neonatorum ...	5	93

MATERNITY BEDS IN LONDON.

At the annual meeting of Queen Charlotte's Maternity Hospital, Marylebone Road, London, Sir Samuel Scott, who presided, stated that there were only 700 beds for maternity patients in the voluntary hospitals of London. Queen Charlotte's Hospital, which last year admitted 1,966 patients to its wards, had frequently to refuse applicants owing to lack of accommodation; the committee had arranged to provide an operating theatre, which had

¹ *The Revised Uniform System of Hospital Accounts*. Fourth edition. London: George Barber. 1926. Price 5s. net; 5s. 4d., post free.

become a necessity, but it contemplated an increase in the number of beds, and for this purpose a large sum would have to be raised. Dr. G. C. Peachey had recently brought to light an interesting fact regarding the foundation of the hospital. He had discovered a manuscript in the British Museum which made it clear that the hospital was founded in 1739, and could thus claim to be the oldest maternity hospital in Great Britain.

QUEEN MARY'S HOSPITAL FOR THE EAST END.

A new pathological department at Queen Mary's Hospital for the East End, Stratford, was opened on April 28th by Lord Birkenhead. The building forms part of the out-patient department, which was erected as the West Ham war memorial, at a cost of £40,000, and opened by Prince Henry in 1924, at which time insufficient money had been received to complete the pathological section. The new department consists of six laboratories with consulting rooms; its equipment is fully comprehensive and up to date, and other hospitals in the district will, it is hoped, benefit materially by making use of it for pathological work. Sir Leonard Lyle, chairman of the hospital, referred to the very active assistance given by Mr. Will Thorne in raising the money for the erection of the out-patient department. Lord Birkenhead mentioned that in the course of last year 130,000 out-patients were treated by the staff, and congratulated the hospital on the value of the work which was being done.

Scotland.

DUNDEE X-RAY PIONEER.

At the meeting of the Carnegie Hero Fund Trustees held on April 29th at Dunfermline the trustees awarded a bronze medallion, together with an allowance of £200 per annum, to George Alexander Pirie, M.A., M.D., of Dundee, who was engaged in x-ray work from 1896 to 1925, and as a result became permanently injured and had to relinquish professional work. Dr. Pirie was recently made the recipient of a local presentation, as announced in our issue of April 3rd (p. 632).

BRITISH MEDICAL ASSOCIATION: FIFE BRANCH.

The last of the series of clinical meetings held by the Fife Branch during the winter took place in the Station Hotel, Kirkcaldy, on April 22nd. The lecturer was Sheriff Dudley Stuart, Sheriff Substitute of Fife and Kinross, who delivered a most interesting and instructive address entitled "Some points from a lawyer's notebook." The importance of a careful, detailed, and thorough examination in all criminal cases was emphasized, and illustrated by anecdotes and references to well known trials. Questions regarding certification, the maintenance of an impartial attitude of mind, not only in medical reports but also in the witness-box, the importance to the doctor of obtaining consent before examination, the circumstances in which the seal of professional confidence may be broken to further the ends of justice, and other points of interest to the medical profession were dealt with from the lawyer's point of view in a manner which was much appreciated by the members present. A discussion followed in which Drs. Douglas, Dickson, Cairncross, Tuke, Macdonald, and Balfour Graham took part. Thereafter the annual dinner of the Branch took place. The chair was taken by Dr. Heron of Markinch (President), and the following guests were entertained: Sheriff Dudley Stuart, Sir Norman Walker, Dr. J. R. Drever (Scottish Secretary of the British Medical Association), Dr. Buist (Dundee), Dr. George A. Allan (Glasgow), and Mr. W. T. Duncan (Fife County Insurance Committee). Dr. C. E. Douglas (Cupar) and Dr. Tuke (Dunfermline), members of the Branch who had both delivered addresses during the winter session, were also present. Apologies for absence were intimated from Professors Murray Lyon, T. J. Mackie, Leonard Findlay, and Dr. Murray Young, and members of the Branch unable to be present. The toast of "The Imperial Forces" was proposed by Dr. MacTier (St. Andrews), and

replied to by Lieut.-Colonel Balfour Graham; and "The British Medical Association" by Sir Norman Walker, who congratulated the Association on having a leader like Sir Robert Bolam, shrewd and far-seeing, who commanded the respect and confidence of the rank and file. He also referred to the work Dr. Drever had done in consolidating the Association in Scotland. In reply Dr. Drever pointed out the satisfactory increase in membership, and also referred to the good work done by Dr. Cox during his visit to South Africa. Dr. C. E. Douglas proposed "The Guests" in an eloquent and felicitous speech, unfortunately curtailed by time. Sheriff Dudley Stuart and Dr. Buist replied. Songs were rendered by Drs. Dickson, McEwen Sinclair, and Lieut.-Colonel Balfour Graham. Thereafter *Floreat res medica* and the usual votes of thanks brought a very pleasant and enjoyable evening to a close.

EDINBURGH MEDICAL FACULTY BICENTENARY.

The arrangements for the celebration of the bicentenary of the Medical Faculty at Edinburgh University, which will be held in June, are now fairly well advanced, although not completely fixed. As already noted in the *BRITISH MEDICAL JOURNAL* of February 6th (p. 252), the Medical Faculty at Edinburgh University virtually began in 1726 with the appointment of Professors Andrew Plummer and John Innes as professors of chemistry and medicine, Andrew Sinclair and John Rutherford as professors of medicine and institutes of medicine, and Joseph Gibson as professor of midwifery. Anatomy, which included surgery, had been taught by Professor Alexander Munro for some seven years previously. As the Towns College at Edinburgh in 1726 for the first time became able to give its own students a complete course of instruction in the subjects required for a medical degree, and began shortly thereafter to examine for and grant the degree of M.D., the year 1926 marks the bicentenary of the addition of a medical faculty to the Towns College, and in a wider sense, therefore, of the transition from the Towns College to the University. The bicentenary celebrations have been arranged to take place on Thursday and Friday, June 10th and 11th. It is expected that a banquet will be held in the University Library Hall on the evening of June 10th, at which it is hoped all the medical teachers of the Edinburgh Medical School may be present. On Friday forenoon the University will confer an honorary degree upon a number of distinguished men, of whom a list was given in our issue of April 3rd, and on the occasion of the laureation it is expected that an address will be delivered by Sir George Newman, chief medical officer of the Ministry of Health. In addition to the list of honorary graduates already announced, the Senatus, by a subsequent resolution, has decided to confer the degree of LL.D. upon Professor W. T. A. Jolly, professor of physiology in the University of Capetown. The Royal College of Surgeons proposes to entertain the honorary graduates at luncheon, and in the afternoon the new department of surgery, presented to the University by the Rockefeller trustees, will be opened by the Secretary for Scotland. The Fellows of the Royal College of Physicians intend to entertain the honorary graduates and others connected with the ceremony at an early dinner on this evening, and the celebration will be terminated by a reception which the Lord Provost and magistrates propose to hold in the Royal Botanic Gardens on Friday evening.

Ireland.

ROYAL VICTORIA EYE AND EAR HOSPITAL.

The need for financial assistance and increased accommodation was stressed at the annual meeting of the Royal Victoria Eye and Ear Hospital, Adelaide Road, Dublin. The report showed that during the year 1,664 patients were admitted to the hospital. In the out-patient department 8,380 new patients were registered, and 4,170 returned for further treatment, making a total of 12,550 who received attention during the year. The aggregate number of visits

paid by these patients was 35,544. The need for additional accommodation became more and more pressing, and the committee looked forward to the time when it would be able to complete the original plans of the hospital. At present there were over forty patients waiting for admission. An order of the High Court in March of last year declared the hospital entitled to the funds available under the terms of the will of the late Mrs. Harvey Lewis. The costs had not yet been taxed, and, pending the realization of investments, it was not possible to state the actual sum available, but it was hoped that over £15,000 would be received. It was hoped to invite tenders shortly for the erection of a new wing to contain about forty additional beds. The cost of the building would be over £15,000, and money would be required for furnishing and equipment. Towards this the committee had nothing in hand. The expenditure was £11,383, and the receipts, exclusive of legacies, were £8,289; £4,238 was received in legacies. Lord Glenavy said that the report was satisfactory, in so far as it showed that the hospital was carried on with increasing efficiency and advantage to the citizens of Dublin and the Free State. Either the income must be increased or expenditure reduced if the hospital was to avoid bankruptcy. He thought there was room for an increase under the heading of paying patients. He was not at all sure that patients were paying anything like the maximum which they should, and this applied particularly to in-patients, who last year paid only £2,797, while the cost of provisions alone was £3,587. Voluntary associations such as that of Messrs. Jacobs would do much to help hospitals.

SHAVING-BRUSHES AND ANTHRAX.

Dr. M. J. Russell, M.O.H. Dublin, in a letter in the daily press states that his attention has been drawn by the Glasgow M.O.H. to the fact that it had just been discovered that shaving-brushes imported from Czecho-Slovakia are infected with anthrax, and that in December, 1925, two gross of these shaving-brushes were consigned from Glasgow to Dublin. It is therefore imperative, in view of the great danger of infection, that any persons who have purchased shaving-brushes at an auction recently should destroy them. No case of infection had yet been notified to him, but that was no guarantee that the continued use of those brushes might not have a disastrous result.

Correspondence.

HYOSCINE IN PARALYSIS AGITANS.

SIR,—The interesting communication on "Hyoscine in post-encephalitis lethargica" by Dr. P. K. McCowan, Dr. J. S. Harris, and Mr. S. A. Mann, in the *JOURNAL* of May 1st (p. 779), prompts me to send you the following note on a method of giving this drug in paralysis agitans, which I have found of great service since I first used it about sixteen years ago.

It is generally agreed that no drug is as effective as hyoscine in controlling the tremor of paralysis agitans, but as a rule the onset of dryness of the mouth or paralysis of the muscles of accommodation makes it impossible to give more than a comparatively small dose. I found that pilocarpine neutralizes the effect of hyoscine on salivary secretion and on the intrinsic muscles of the eye without in any way diminishing its effect on the tremor. Consequently a much larger dose can be given than would otherwise be possible. The further addition of strychnine helps to prevent the depression caused by the hyoscine, again without diminishing its influence on the tremor. I generally begin with a mixture containing gr. 1/200 hyoscine hydrochloride with gr. 1/15 pilocarpine nitrate and π 3 liq. strychninae given four times a day. The dose is then very gradually increased till the tremor is controlled or unpleasant symptoms are produced. In most cases it is possible to give gr. 1/50 hyoscine, in many cases gr. 1/20, and occasionally as much as gr. 1/8 without any troublesome dryness of the mouth, paralysis of accommodation, or other unpleasant symptoms being produced. The dose of pilocarpine is at the same time increased, but not

in proportion, gr. 1/6 being generally the maximum, and the dose of strychnine may be increased to π 5 or 6. By these means the tremor can be much more completely controlled than by giving the drug alone, and also without having recourse to subcutaneous injection.—I am, etc.,

Windsor Forest, Berks, May 1st.

ARTHUR F. HURST.

SIR,—In the interesting article on hyoscine in post-encephalitis lethargica, by Drs. McCowan, Harris, and Mann, doubt is expressed whether some of the beneficial effect noted is not due to suggestion. While it is impossible to exclude altogether its effect from any form of treatment, the authors of the paper seem to have demonstrated, in a striking and unusual manner, from their investigations on the blood sugar curve, that suggestion had nothing to do with the improvement they observed. It may, moreover, be stated with confidence that post-encephalitic Parkinsonism is a condition which is singularly unresponsive to suggestion when administered by the common psychotherapeutic methods.

The authors go on to say that "It must be more than coincidence that the hysterical element is here [that is, in post-encephalitic conditions] found to an extent not approached in any other group of patients found in a mental hospital." Equally it cannot be a coincidence that these patients are almost the only ones with so-called hysterical symptoms where no effect whatever is produced by direct psychotherapy. And this naturally raises the question: Is there really an hysterical element in these symptoms at all? That many doctors think so is undeniable. At the Cassel Hospital we are constantly receiving applications that patients be admitted with functional symptoms following on encephalitis. The ground for such a statement has usually been that the doctor in his consulting room has by persuasion then and there induced the patient to perform certain synergic movements much better than they could be performed before. The very rapidity of the result is an indication that it is of no value; hysterical symptoms are not modified in this easy fashion. The explanation, however, is simple. In post-encephalitic rigidity the lesion is one affecting automatic movement. So long as the patient is using his voluntary system which is comparatively unaffected—that is, so long as he is giving close conscious attention to his movements—he will get a better result; but as no one can continue to do this for more than a very few minutes there is no practical result to be gained by persuasion, re-education, or any psychological method.

The question whether these symptoms should ever be spoken of as hysterical—though indeed they may simulate hysteria—is of importance from the hope which the authors have that here may be found an organic basis for hysteria. If the symptoms only resemble those of hysteria but are not identical with them, then we have not approached any nearer to an organic explanation of this disorder. But if the symptoms of the post-encephalitic are the same as those of hysteria we are at once plunged into a difficulty greater than that in which we are at present. We shall then be compelled to acknowledge that suggestion can have an effect on what the authors call "subtle biochemical or biophysical abnormalities," for they themselves freely acknowledge that suggestion has some effect on hysteria. This is to acknowledge psychogenesis, but a psychogenesis of a peculiarly incomprehensible order.

Is it not simpler to say that there are two categories, mental and physical; that though they interact we do not know how; that each may produce similar symptoms, though fortunately we have learnt in certain cases to distinguish between them; finally, that, so far, nothing is to be gained by explaining the one in terms of the other?—I am, etc.,

T. A. Ross.

ADOLESCENT ALBUMINURIA.

SIR,—I have no doubt that many of your readers will have felt inclined to echo the surprise of your correspondent Dr. Claude Wilson that anybody should have sought instruction for the treatment and "cure" of orthostatic

CORRESPONDENCE.

846 MAY 8 AND 15, 1926]

846 MAY 8 AND 15, 1920]

albuminuria, a condition which has surely been accepted as a vasomotor peculiarity and perfectly innocuous.

But I would like the privilege of referring to Dr. Wilson's opinion that the albuminuria which results after severe exercise is an exaggerated tendency of the same kind and, as he puts it, physiological. Dr. Wilson refers to Dr. Collier's well known observation that albuminuria occurred in every member of an eight after rowing a course. I have investigated the effects of track athletics upon a fairly extensive scale: in many cases the feats of exertion have been of the greatest severity, certainly at least equivalent to the ordeal of rowing from Putney to Mortlake; yet subsequent albuminuria has been conspicuously absent. I can recall only one really definite example—a Marathon runner who had completed the distance without any signs of disproportionate distress or exhaustion: a considerable degree of albuminuria with hyaline and granular casts persisted in this instance for thirty hours. But a close inquiry into his history elicited the information that he had suffered from nephritis—probably scarlatinal—as a child, and that at the age of 25 he had been in hospital for so-called "war nephritis." From my own experience I have always been of opinion that the albuminuria described by Dr. Collier and others as occurring in oarsmen is not due to the exercise *qua* exercise, but depends upon mechanical factors which are easily invoked in the case of rowing and obviously absent in running.

It would be of some interest to determine what is the recognized orthostatic albuminuria, and to ascertain its effects, and, secondly, other forms of violent exertion.

described by Dr. Wilson, and is not due to the exercise quite as easily invoked. The mechanical factors which are absent in running, of rowing and obviously present in rowing, are of some interest to determine what is the effect upon subjects of recognized orthostatic albuminuria, first, of hard rowing, and secondly, other forms of violent exercise. It would also be interesting to ascertain if "rowing albuminuria" can be related to the duration or to the comparative severity of the exercise. That exercise alone, however severe, can be responsible I find it difficult to believe; and even though some objection may be taken to the description of "physiological" as applied to a sequel of rowing, it would seem that any renal change which is produced must be of the most trivial and ephemeral nature.

My acquaintance with athletic young men in the early twenties certainly encourages a belief in Dr. Wilson's suggestion that "adolescence" may, in many cases, be a comparatively protracted affair; and that so far as certain localized tendencies are concerned the subjects, as he puts it, "never grow up."—I am, etc.,

THE SPAHLINGER TREATMENT.
C. E. Jenkins (BRITISH MEDICAL
... with the Science of affair

THE SPÄHLINGER TREATMENT.

SIR,—Dr. C. E. Jenkins (British Medical Journal, May 1st, 1926, p. 805) agrees with the Science Committee (1) that it is wise in the present state of affairs to refrain from expressing an absolute opinion on the efficacy of the Spählinger treatment; (2) that the treatment ought to be put to a lengthy and vigorous trial under medical supervision in this country; (3) that the investigations suggested by the Science Committee are reasonable and practicable; (4) that an appeal for funds to meet the expense of these investigations is worthy of support; and (5) that in the circumstances M. Spählinger need not be urged to disclose publicly any laboratory methods which he desires to reserve.

In view of this agreement the members of the Science Committee naturally welcome any form or degree of co-operation which is in a position to afford and with some

In view of this agreement the members of the Science Committee will naturally welcome any form or degree of co-operation which Dr. Jenkins is in a position to afford them. It is true that in a rapid phrase, and with something less than courtesy, Dr. Jenkins impugns the good faith of the Science Committee. The charge is too absurd to be taken seriously, and the memory of it will not disturb the Committee's desire to encourage an enterprise to which its word is pledged.—I am, etc.,

C. O. HAWTHORNE,
Chairman of the Science Committee.

London, May 1st.

COMMON SENSE IN RELATION TO DOUBTFUL
TUBERCULOSIS.

COMMON SENSE IN RELATION TO
TUBERCULOSIS.

SIR,—I would like to add my testimony to that of Dr. Weatherhead that there is no appreciable risk of infection of non-tuberculous persons at a well ordered sanatorium. The question of a well ordered sanatorium is beside the

point. The Ministry of Health has been in many cases obliged to approve of certain sanatoriums as the lesser of two evils. That emergency is, however, fast becoming a thing of the past as the tuberculosis scheme develops, and the standard, slowly, it is true, but surely, is being raised as circumstances permit, and as increased knowledge among the profession as well as the laity renders it possible.

I again agree that it is high time that this body of infection should be laid. It is monstrous to think that people have been deterred from seeking health at such a centre as Davos by the intimidation of infection. Many years ago the late Dr. Huggard had to fight against this misrepresentation. The history of the conjugal relations of marital life shows that the incidence of infection is no higher than in ordinary life. What greater proof is needed? The great susceptibility of infancy rapidly diminishes after the third year.

I have lived practically my whole life since my teens in close association with tuberculosis, either in Switzerland, in hospital, as medical officer to a sanatorium, in tuberculosis dispensaries, or in tuberculosis pavilions during the war, and I have never in any of these resorts known a case in which infection was so traced. During eighteen years at Stanington Sanatorium, where we have children of the most tender years and a staff of some seventy maids and nurses, no such case has come under my notice. Even if a case previously without physical signs were returned to us with definite physical signs, it would prove nothing. Any person with a lowered line of life is liable to become a victim to tuberculosis; if that line is lowered and not heightened at a sanatorium, the sooner its doors are closed the better.

to us with a low voice, "Any person with a low voice is a victim to tuberculosis; if that person is brought to a sanatorium, the sooner its door is closed the better."

The consumptive in this country has been painfully bungled and mishandled for over thirty years. The voice of those who have been through the mill—the tuberculosis officers and medical superintendents—rings out clear and unmistakable, "Send us the cases early, the earlier the better"; if amongst them are a few mistakes, they will be quickly sorted out and labelled "non-tuberculous." When one comes to have over treatment of a case of haemoptysis, I think the limit has been attained. A great authority says: "There is only one excuse for not giving a patient who suffers from an early haemoptysis the benefit of early diagnosis and early treatment, and that is, failure on his part to consult a physician."—I am, etc.,

T. C. HUNTER, M.D.,
Medical Superintendent, Stanington Sanatorium.

MENTAL IRRITABILITY AND BREAKDOWN
IN THE TROPICS.

April 28th.

MENTAL IRRITABILITY AND BREA
IN THE TROPICS.

SIR,—I think Dr. R. Murray Barrow's letter in the *JOURNAL* of April 3rd (p. 634) shows that it is possible to get "nervous breakdown" in widely differing climatic conditions. Dr. Barrow fixes the blame on "the brightness of the sun's rays." I cannot agree with him, as I have met some of the most placid and mild-mannered people who have spent a long life in tropical climates. Bright sunlight, especially if reflected, is a violent irritant to the unprotected eyes, and through them to the nervous system. I have experienced severe headaches due to this when motoring on the white roads of Southern England, and in France, but found complete relief by wearing a pair of greenish-amber coloured glasses.

While I do not agree that it is "the brightness of the sun" that causes these cases of nerve irritability, I think that in places where the sun is visible and invisible, the trouble is the same.

to the unpurged system. I have experienced when motoring on the white roads and in France, but found complete relief by pair of greenish-amber coloured glasses.

While I do not agree that it is "the brightness of the sun's rays" that causes these cases of nerve irritability, I have no doubt at all that in places where the sun's rays are powerful and prolonged the visible and invisible rays of the sun are the *fons et origo* of the trouble. Both in "bracing" places like Alberta and the Kenya Highlands, and in "depressing" tropical places where there is rarely a breeze, the sun's rays increase the metabolic activity of the body at an altogether abnormal rate. This is shown by increased perspiration (I have perspired freely when climbing a glacier in bright sunlight), increased heart rate, loss of weight—amounting in some cases I have seen to emaciation—and the feeling that more food and drink is required. It is therefore a wise plan to rest when possible during the hottest part of the day,

and so lessen the metabolic activity of the tissues—directly by resting brain and muscles, and indirectly by keeping out the rays of the sun.

In both bracing and depressing places it is essential to protect the head, the eyes, and the body from the heat rays and chemical rays of long-continued strong sunlight by coloured glasses if necessary (especially from reflected light) and the use of special clothing, as suggested in my previous letter (March 27th, p. 595). The rationale of the mode of production by the sun's rays of these cases of nerve exhaustion is probably, however, subtly different in bracing and depressing places—that is, places where there are few winds and comparative air stagnation exists. During Dr. Barrow's first winter in Alberta he felt "energetic and invigorated," due to the sun's rays increasing his metabolic activity. As the weather was very cold he would not perspire, as in the tropics, and this would put a more severe strain upon his digestive apparatus, kidneys, and lungs. Being themselves "speeded up" by the sun's rays and the bracing atmosphere, these organs performed their extra task with ease the first winter, as evidenced by his feeling of well-being, but by the third winter "he became more irritable, more sensitive to cold"—"one's blood got thinner." If he had said his blood by now was loaded with toxins, owing to the temporary failure of the appropriate organs to deal with them, due to exhaustion, after being "speeded up" for two years, he would have been correct, I think, and I have no doubt that his irritability was due to toxæmia produced in this manner.

It is interesting to note that Dr. Barrow observed that alcohol and anaesthetics were extremely rapidly absorbed, showing metabolic activity to have been very great. In the summers which were stormy, damp, and hot the nervous irritability was not felt so much because, of course, of the joint action of perspiration and of winds on the body. In a depressing tropical place with little wind movements the nervousness is also, I believe, due to a toxæmia originated, as before, by the sun's rays. In healthy people whose organs are in good order there is here also some preliminary feeling of well-being (along with the discomfort) caused, as before, by increase of metabolism produced by the sun's rays, and also by the ingestion of stimulating new foods and drinks. The attention is distracted also by the strange new life, and the discomforts thus minimized. Owing to the absence of winds, however, perspiration is not adequately evaporated, and as there is no play of air round the body noxious gases given off by the skin remain in contact with it. The lungs and other organs are also not so active as in a "bracing" climate, so that from the first the individual in such a place suffers from toxæmia. The toxins themselves for a while will stimulate the excretory organs, but this, like the effect of alcohol, is evanescent.

As showing the remarkable effect of winds upon well-being in the tropics, I may say that some years ago I was for some little time at Pukow (across the river from Nanking). There I saw two very bad cases of mental irritability in Europeans. One of these men actually lived there in a tent, whilst the other crossed the river to Nanking to sleep and to have some of his meals, but was for the most part at Pukow. Another European in the same service, and several others in different service, but who were all most of their time in Nanking, were bright and cheerful and indulged in sport and games. Both the normal and the irritable ones took alcohol and smoked tobacco. The only difference that I could see was that there was generally a gentle breeze at Nanking, as there are hills quite near, whilst at Pukow it was sweltering and still. Pukow then consisted of a few junks, a small stage, and an immense flat swamp. It was summer time, and exceptionally hot at that, I was told.

As regards Dr. J. W. Thomson's suggestion that the condition of nervous irritability may be due to a deficiency of electrical content in the air of the tropics, it is well known that the composition of the air in different localities is remarkably constant, and so the electrical ions must also be constant. Anyone sailing along the coast of Cochin China at night is quite convinced that there is plenty of electricity there, for generally the mountains along the

coast are ablaze with gigantic lightning flashes resembling an artillery engagement on a huge scale.

It would appear, then, that "bracing" and "relaxing" places alike, if endowed with long-continued strong sunlight, are dangerous to the nervous system, and I believe the reasons to be what I have suggested. As to the means of combating these effects, I hope the suggestions given in my previous letter, and amplified and more reasoned in this one, may be of use. *In media tuta*, as in so many things, appears true of tropical places, or where there is strong sunlight—that is, if one could choose, it would be well to be at a moderate height, or at sea-level near a range of hills, where there is generally a gentle air movement.—I am, etc.,

ANDREW S. McNEIL, L.R.C.P.S.Ed.

Liverpool, April 2nd.

SIR,—The very varying replies to the Bishop of Singapore's letter seem to indicate that there is no agreement as to the main cause of the frequency of nervous symptoms so common in Englishmen abroad. The Association of Medical Officers of Missionary Societies, of which I am honorary secretary, has discussed this subject frequently since the war terminated. While we have formulated no decision on the subject, our deliberations would seem to indicate that the trouble is more due to changed environment than changed climate, and that the remedy lies in an appreciation of the danger, and a knowledge of psychological facts. Our 1923 edition of "Health Instruction for Missionaries," after speaking of daily habits, and the increased strain due to new conditions and environment, advocates "sanctified common sense" as the main safeguard.—I am, etc.,

London, E.4, April 30th.

L. E. WIGRAM.

NAPOLÉON'S PRIZE FOR RESEARCH ON CROUP.

SIR,—The following short account of a medical episode in the life of the great Napoleon may be of interest to your readers.

When Josephine de Beauharnais was married to General Bonaparte she had two children, the younger of whom, Hortense Eugénie, married in 1802 Louis Bonaparte, brother of Napoleon. Later in the same year a son was born to them. The birth of this boy was an event of the very greatest political importance, for in view of the childlessness of Napoleon and Josephine, now emperor and empress, he was a possible heir to the throne of his uncle, and future ruler of France. As a matter of fact, had he lived, he might have ascended the throne in 1852, in place of his brother Napoleon III. Unfortunately this child died of croup in 1807. The news, when conveyed to Napoleon, caused him, as was characteristic, to take some action in the matter, and, although at the time engaged in a strenuous campaign in Russia, he dictated the following letter from army headquarters to his Minister of Foreign Affairs:

"Monsieur Champagny,—Depuis vingt ans il s'est manifesté une maladie appelée *croup*, qui enlève beaucoup d'enfants dans le nord de l'Europe. Depuis quelques années elle se propage en France. Nous désirons que vous proposiez un prix de 12,000 francs, qui sera donné au médecin auteur du meilleur mémoire sur cette maladie et sur la manière de la traiter.

"NAPOLÉON."

As far as I can ascertain only two essays were sent in as the result of this offer, one from Geneva and one from Bremen, neither of which seems to have been of much moment, and I can find no record of the prize of 12,000 francs having been awarded.

The facts that the young prince was 5 years of age, and that his attack was fatal, point clearly to the disease having been diphtheria.—I am, etc.,

L. A. PARRY, F.R.C.S.

Hove, April 18th.

CARBONIC ACID AS A PRESERVATIVE.

SIR,—In making experiments relative to the cause of decomposition, I secured a number of newly laid hens' eggs and placed one in a jar of each of the following gases: oxygen, hydrogen, nitrogen, air, carbonic acid.

After standing for a period of about five months these jars were opened; those containing oxygen, hydrogen, nitrogen, and air gave off a most repulsive odour, and the eggs were decidedly bad.

The jar containing carbonic acid, when opened, gave off practically no odour, and the egg, when opened, was pure and fresh. When poured on to a saucer it had all the appearance of a newly laid egg.

As the result of this observation I made further experiments and examinations, with equally good results.

In one case, where the egg had been standing in a jar of carbonic acid for about four months, the limo salts of the shell were partly dissolved, probably due to the acetic acid used to generate the gas from sodium bicarbonate, but the membranous material was quite healthy. This, when opened, was found to contain a yolk and albumen in a state of perfection, without discoloration or odour.

My observations on eggs and other material lead me to believe that in carbonic acid, freshly generated, we have a preservative which may be of incalculable value from commercial and scientific standpoints.—I am, etc.,

H. E. JONES, M.B., C.M.

Glasgow, April 25th.

DR. YOUNG'S CANCER PARASITE.

SIR,—Dr. Leitch's statement (BRITISH MEDICAL JOURNAL, May 1st, p. 808) that the object of the test experiment carried out at his laboratory was the production of "straightforward cancer" is disproved by the following letter written by me to him on May 10th, 1924:

"Dear Dr. Leitch,—I have had a letter from Sir Walter Fletcher saying that you have kindly agreed to test out in your laboratory an experiment which I have carried out with an organism obtained from mouse carcinoma. I have professed to show that in a considerable proportion of inoculated animals a progressive lymphomatous lesion of the nature of pseudo-leukaemia and, in an advanced case, of lymphosarcoma, is produced. I enclose a copy of the paper in which I describe this lesion, and I propose, with your permission, to show you the actual slides. I have claimed that this finding is relevant to cancer research because:

"(1) The leukaemic process is considered by many observers as exhibiting all the stages between a benign neoplasm and a malignant new growth.

"(2) The evidence is strong that these have an infective origin, and my own experiments are capable of being interpreted as implying a blood infection with a tumour-producing organism.

"(3) Maud Slye's experiments suggest some relationship between pseudo-leukaemia and cancer.

"I would suggest that you be kind enough to provide me with two mice with an easily transplantable carcinoma and that from these I would attempt to isolate an organism which you or your assistant would inject into a considerable number (say fifty with fifty controls); the results to be noted by you. I shall await the arrival of the mice, and after the isolation of the organism will write you to make further plans.—Believe me, yours very truly, JAMES YOUNG."

—I am, etc.,

Edinburgh, May 1st.

JAMES YOUNG.

THE "SPECIAL REPORT SERIES" OF THE MEDICAL RESEARCH COUNCIL.

SIR,—I do not care to engage in controversy with those who, like Dr. Greenwood, in order to distract attention from the inaccuracy of their arguments, abuse the amenities of scientific discussion by descending to the use of stupid personalities.—I am, etc.,

Liverpool, May 3rd.

W. BLAIR BELL.

NASAL PLASTIC REPAIR.

SIR,—I desire to thank the several surgeons who have written on the subject of my article on nasal plastic repair in your issue of November 28th, 1925 (p. 987). The device described was so slight a departure from well established methods that it is not surprising to learn that some of them, as well as myself, have been using it for several years. I wish especially to thank Professor G. Portmann of Bordeaux for kindly sending me a reprint of his own article from the *Revue de Laryngologie* of 1923, describing a practically identical method.—I am, etc.,

Bristol, May 4th.

E. WATSON-WILLIAMS.

Obituary.

WILLIAM FREDERICK SHANKS, M.B., CH.B. GLASG.,
Professor of Physiology, Leeds.

THE untimely death of William Frederick Shanks, Professor of Physiology in the University of Leeds, which occurred on April 15th, came as a shock to his many friends, both in the academic world and in the medical profession generally. He had but recently left the post of lecturer in experimental physiology in Glasgow University to take up the appointment in Leeds rendered vacant by Professor Raper's transfer to Manchester, and his former colleagues and many of the students in the Glasgow School learnt with very deep regret that their friend and teacher had been spared to occupy his new and well deserved position for so short a period.

He was born in Glasgow in 1888, matriculated at Glasgow University in 1909, and graduated B.Sc. in pure science in 1913, specializing in physiology, in which subject he gained special distinction at the degree examination. Thereafter he completed the medical course, qualifying as M.B., Ch.B., and graduating with commendation in 1915. Immediately afterwards he joined the R.A.M.C., and was attached to the R.F.A., with which he served in France until, in 1919, he was demobilized in order to return to his university as assistant in the department of physiology.

In October of the same year he was appointed lecturer in experimental physiology. This post he occupied during a particularly difficult period, when the normal number of students was trebled by the return to study of those who had had their curriculum interrupted by war service. Extremely conscientious in all his works, he was particularly so in regard to his teaching duties, and his able conduct of the medical and science classes during this onerous period was of inestimable value to the senior staff. A capacity for clear and concise exposition in his lectures, his ever-willing assistance in the technical difficulties of the practical class, and a faculty for appreciating their point of view, rapidly won for him a high place in the estimation and affections of the students.

In October, 1923, at a comparatively early age, he was appointed to the chair of physiology in Leeds University in succession to Professor Raper. In his new appointment the ability and sterling qualities which he had displayed in Glasgow rapidly gained for him honour and affection from his staff; he relinquished the research work for which he had with difficulty managed to find time in Glasgow, and devoted his whole time to the organization of his new department.

Great as were the demands of teaching in the early post-war years, Shanks published a number of papers in the *Journal of Physiology*. Much of the research work in the Glasgow Laboratory at that time was being directed towards defining the relationship of infantile tetany and tetania parathyreopriva, and to the probability of both being caused by guanidine intoxication. The relation of methyl-guanidine to creatin on the one hand and to cholin on the other suggested a repetition of Riesser's work on the conversion in the body of cholin into creatin. Of this conversion Shanks found some confirmatory evidence, and this led to a further investigation on the presence of excess cholin in the blood of parathyroid-ectomized animals. This was followed by an investigation on the disappearance within the body of cholin which had been subcutaneously or intravenously administered; a communication on this subject was made before the International Physiological Congress of 1923. A fourth paper appeared on the excretion of cholin in the urine.

All his research work was characterized by the same conscientious attention to detail that he had exhibited in his teaching; he was always on the look-out for possible sources of fallacy; he would freely discard any experiments in which there seemed the slightest flaw of reasoning or technique. It is a matter of very sincere regret with all those who have been associated with Professor Shanks, either in Leeds or in Glasgow, that he was not spared to see the fruits of his labour in Leeds, and to prosecute

further the research work which he had commenced in Glasgow.

In July, 1924, Professor Shanks married Miss Pearl S. Henderson, B.Sc., a lecturer on the staff of the Glasgow Institute of Physiology. Much sympathy will be felt for her and for Professor Shanks's mother and sister in their sad bereavement.

FREDERICK STEPHEN PALMER, M.D., F.R.C.P.,
Consulting Physician, West End Hospital for Diseases of the Nervous System.

We regret to announce the death of Dr. Frederick Stephen Palmer, on April 21st. He received his medical education at the Westminster Hospital, and obtained the diplomas M.R.C.S.Eng. and L.S.A. in 1869. He then held house appointments at the Westminster Hospital and the Radcliffe Infirmary, Oxford, after which he began general practice in East Sheen. He graduated M.D. Durham in 1885, and in 1901 obtained the diploma of M.R.C.P.Lond. In that year he gave up his practice in Surrey and removed to London, where he worked at the Hospital for Sick Children, Great Ormond Street, and the National Hospital for the Paralysed and Epileptic, Queen Square. In 1904 he was elected physician to the West End Hospital for Diseases of the Nervous System, and for many years was physician to the Hostel for St. Luke and the Royal Society of Musicians. In 1911 he was elected F.R.C.P. He was an ex-president of the West London Medico-Chirurgical Society, and a former vice-president of the Medical Society of London. He was appointed consulting physician to the West End Hospital for Diseases of the Nervous System in 1921. Dr. Palmer was the author of numerous articles on neurological and general medicine.

A colleague writes:

Dr. Frederick Palmer's sound practical knowledge, gained at the Radcliffe Infirmary, where he was resident for some years, coupled with his natural gifts of energy, kindness, geniality, tact, business instinct, and personal charm, were bound to secure for him a prominent position in the profession. The courageous step he took, when well advanced in life, in abandoning general practice in London, was thoroughly justified by events. The wisdom of his election as a physician to the West End Hospital for Diseases of the Nervous System was proved by many years of skilled and devoted service to the hospital, and by the affection he inspired in all connected with it. His professional ability and status as a physician were acknowledged by his election to the Fellowship of the Royal College of Physicians of London, a distinction he greatly valued. He was rarely absent from important functions of the College, and he made many friends among the Fellows. Dr. Palmer faithfully obeyed the admonition "Judge not." I never knew him, either directly or by veiled innuendo, to cast aspersions on others. He was happy, serenely happy, in his home life, and was fond of music, history, and biography. Golf he never succumbed to, but many an off afternoon was spent in walks round and about London with his long-time friend Dr. de Havilland Hall. Though advanced in years Dr. Palmer was singularly youthful in mind and body, and it was a great grief to his many friends when they learnt that he had fallen a victim to an attack of virulent influenza.

Dr. DAVY T. BELDING of East Dereham died on April 15th, aged 62 years. He was the son of the late D. T. Belding of South Creake Hall, and studied medicine at St. Bartholomew's Hospital. He was prosecutor at the Royal College of Surgeons of England in 1886-87, and took the diplomas of the Conjoint Board in England. He became a partner of Dr. Hastings of Dereham, and subsequently succeeded to the practice. He was medical officer of health for the East Dereham Urban District and the Mitford and Launditch Rural District, and certifying factory surgeon. During the war he served with the East Anglian Territorials, became A.D.M.S. of the East Anglian Division, and was transferred to the Eastern Command when the Division went to Gallipoli. At the conclusion of hostilities, when he held the rank of brevet lieutenant-colonel, he returned to his practice. He took great interest in golf, was an original member and an ex-captain of the Royal Norwich Golf Club, and a member of the Royal West Norfolk Golf Club since 1892. Dr. Belding, who was a member of the East Norfolk Division of the British Medical Association, is survived by his widow and a daughter.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

Birth Control.

THE question of the advisability of imparting information regarding methods of birth control was discussed at length in the House of Lords on April 28th. It arose on a motion by Lord Buckmaster, requesting the Government to withdraw all instructions given to or conditions imposed on welfare committees to cause them to withhold from married women in their district information where sought by such women as to the best means of limiting their families. Lord Buckmaster pointed out that whereas fifty years ago the advocacy of birth control was attempted to be punished by the criminal law, the only question to-day was whether steps should be taken to withhold from the poor the knowledge possessed and practised by the rich. All the books dealing with this question treated it as an axiom that birth control was being extensively practised by the well-to-do, and that it was only among the poorest and most ignorant stratum of society that that knowledge had not permeated and was not used. Statistics showed that for 1,000 married people, under the age of 50, the birth rate for schoolmasters was 95, for clergymen of the Church of England 100, for clergy of all denominations about 102, for doctors and professional men from 103 to 105, for skilled labourers 153, and for unskilled labourers 247. There was a descending scale of intelligence in exact inverse ratio to this standard of birth rate. The present position was that the Ministry of Health would provide money for assisting welfare centres to give help and advice to women expecting children or who had young children under their care. But there was an expressed prohibition that prevented these people, although they were qualified medical men and women, from being able to give information to any person who asked them as to the means by which further births might be prevented. His motion laid no burden and imposed no duty on any medical officer of health. It did not even contain directions that it should, or say that in the opinion of the Ministry it ought to be done. It was to let these qualified medical people, if they in their judgement thought fit, exercise their medical knowledge for the relief of the women who came before them. Cases in which pregnant women did everything they knew to procure abortion would continue if the women were not allowed to obtain knowledge by which they could prevent themselves having children. They were living in a world of sham or in a "cloud cuckoo land." Every now and then cases came before the courts and some person was sent to gaol for performing an illegal operation. If women asked for information by which they could prevent children they could not be given it, because, if they were, the grants would be stopped. What, asked Lord Buckmaster, was the answer to the case he had put? It was said that directly they limited the birth rate they began to descend in the scale of the world. Was the measure of nations to be tested by their fecundity like rabbits? It was not a question of numbers, but of quality. While he spoke with deep respect for the deep-rooted religious objection to the proposal, he could not understand the ground on which it was based. Human nature being what it was, the doctrine of abstinence was impossible.

The Marquess of Salisbury (Lord Privy Seal) opposed the motion on behalf of the Government. He said that what was really concerned was the success of the great policy of hygiene, which had been the characteristic of the last half-century in this country, and which had met with such success. While they all regretted the sorrow and misery to which Lord Buckmaster had referred, they must be careful that in finding a remedy for them they did not strike a fatal blow at a great service which was doing infinite good to the very class for which he pleaded. The maternity and child welfare system had grown enormously, and there were now over 400 committees. Under the committees were over 2,000 centres all over the kingdom, engaged in the work of helping expectant mothers or those who had just had children. The movement was taken advantage of by a very large proportion of expectant mothers and those whose children were just born with such success that the mortality among children under 1 year had gone down by 50 per cent. since the beginning of the century. The Mothers' Union, as well as large numbers of religious bodies, were against Lord Buckmaster's proposal. It would be extremely rash to do anything which would interfere with the success of the centres. If the medical officer were given unfettered discretion to give information he would give it in his official position. If he were attached to the centre, how could he discriminate? It would not only be the sick and miserable women, whose health had been... apply; there were also indolent and vicious doctor discriminate and refuse to give or he had given to another? (Lord Buckmaster: Why not? Private doctors do.) But this was an official doctor, and he would have to accept each case. The impression in the public mind would be that the Government had agreed that henceforward, so far as its official sanction was concerned, a woman might choose for herself; it did not even matter what her husband thought. Again, although some defective women might go to the centres, the women whose mental condition made the results so deplorable were not the people who went for assistance to anybody, because their minds were not qualified to form a rational conclusion. It was also untrue that the hard cases could not get relief. They could go to the doctors for a relatively small fee just as richer people could, and it was a great mistake to think that they were entirely ignorant in these matters. The fall in the birth rate was a very serious thing. In the decade 1871 to 1880 the births were 35 per 1,000. In 1924 they were only 18 per 1,000. The population was increasing because of the shrinking death rate, and not the increasing

birth rate. The real catastrophe before European civilization was that the white races would begin to diminish, and nothing must be done to assist that.

The Archbishop of Canterbury also opposed the motion. He said that the maternity and ante-natal centres and the infant welfare centres might be, and constantly were, worked together, though they were not necessarily dependent on each other. Their object was to secure healthy birth in the interests both of the mother and the child. This was secured by the observance being taught to mothers of well ascertained and well established laws as to the pre-natal treatment of both mother and child. There were to-day 2,122 centres in England, and at 611—nearly one-third—pre-natal work was carried out. Prior to the formation of any such centres the death rate of children under 1 year was very high. In 1905 it was 128 per 1,000, in 1910 it had fallen to 110, and it was now 75 per 1,000. There were also a good many birth control clinics, supported either by voluntary subscriptions or the fees of parents, or both. These were primarily, and even avowedly, for giving advice to married women who desired to limit their families or not to have another child. They professed to give their advice only to married women. In the maternity centres with which his friends were concerned no distinction was drawn as regarded giving advice and help between married and unmarried expectant mothers, and they were equally careful with both. The Archbishop said he made no kind of suggestion that there should be any restriction or interference with the birth control centres, which had been established by those who desired to use them and were supported by some exceedingly thoughtful people. He knew medical men and health visitors who were at work in some of the large maternity centres. He had got into touch with them, and he found a perfect assurance everywhere, first, that the number of applications for advice of the particular kind under discussion was rare, and, secondly, that no restraint whatever was put on the doctor if, on medical grounds, he thought it necessary to give advice respecting child-bearing, but he was under no obligation to give such advice. He was not there as a public officer who was bound to give an answer to an inquirer on that particular subject. That was rightly so. Very many of these people objected on principle to giving such advice in anything but the most rare and exceptional way, and if they were bound to do it on every inquiry they would feel themselves in an impossible position. Many of the other patients objected to the use of the centre for such a purpose, as did many of the outside public. The power of the doctor to give individual advice was not restrained. If they passed this resolution they would lay on these medical practitioners, who were public officers, a moral obligation to give that advice to groups who asked for it. The two regulations which existed stated: (1) "That the maternity and infant welfare centre should deal only with the expectant or nursing mother (and infant) and not with the married or unmarried woman contemplating the application of contraceptive methods." (2) "It is not the function of an ante-natal centre to give advice in regard to birth control, and exceptional cases where the avoidance of pregnancy seemed desirable on medical grounds should be referred for particular advice to a private practitioner or hospital." He did not think the second of these rules was worded in the best way or was exactly what the Ministry of Health meant. But the medical man or woman, in his judgement, wanted to be protected against having the moral obligation laid on him or her to give advice on this subject of contraceptives, which advice he or she might not wish to give, and which those supporting and guiding them did not wish should be given. In order to satisfy himself further, he had made inquiry from some of the highest authorities in the Ministry of Health and had drawn up the following memorandum from conversations he had had with the highest authorities as to what happened now: "In all cases attending the clinics where this information is necessary on medical grounds advice is always given by the doctor, irrespective of any request on the part of the mother. Neither by the wish of the mother nor by statistical evidence have we been led to believe there is any great demand for this kind of advice. In suitable cases recommendations have been strongly made that the use of contraceptives should be discontinued, and we have reason to know that the advice has been acted upon with satisfactory results. The extreme medical cases in which another birth would be likely to prove disastrous to the mother are few and far between. Such cases would not ordinarily attend a maternity and infant welfare centre; but if and when they did, it may be safely assumed that the mother would be advised as to the right course to adopt in order not to have any more children. The purpose of the maternity and infant welfare centre is to deal only with the expectant or nursing mother (and her infant) and not with cases of disease on the one hand or, on the other hand, with married or unmarried women contemplating the application of contraceptive methods. The object of these centres is—(1) to advise the expectant and nursing mothers; (2) to provide ante-natal supervision; and (3) to care for the infant. In order to conserve the purpose of these maternity and infant welfare centres it was necessary to exclude any systematic or organized work in the direction of contraception." It was made perfectly clear that no sort of restriction was placed on medical men. He asked, further, whether, if the medical man or woman did give this advice, it would mean either the withdrawal of the grant or discredit to the individual. The idea was laughed at and he was told "Nothing of the kind." There was no sort of interference between the patient and the doctor desired or thought of. If that was so, what became of the resolution? They were really asking for something to be withdrawn which did not exist. He hoped that the wording of the second of the regulations would be revised by the Ministry of Health. He could not help thinking that the resolution was based on a misunderstanding. Another question was: What was the medical knowledge which was supposed to be used by those who, if Lord Buckmaster had his way,

would be encouraged definitely to give that advice. The opinion of Lord Dawson of Penn, who was not present that day, carried great weight. He had had talks with him about it, and he had read the evidence which Lord Dawson had given on the subject. He would quote what he said: "Up to now there has been no systematic investigation of contraceptive methods by the medical profession in this country, though such an investigation is now proceeding in the United States." In those circumstances, and with the uncertainty of knowledge on the subject, it would be intolerable to lay on the medical authorities the duty of giving such advice.

Viscount Fitzalan of Derwent contended that in view of the divergence in medical opinion no Government was justified in taking the course demanded by Lord Buckmaster. He proceeded to read a list of eminent physicians who were against proposals connected with birth control. The welfare group of the Society of Medical Officers of Health discussed the question at its annual meeting last July, but no resolution in favour of birth control was passed.

Earl Russell said that it was true of most branches of medicine that they had not devised the most perfected treatment. For instance, they knew very little about cancer. But that was no reason for not using the best medical knowledge that was possible or for not doing what they could with the knowledge they had.

The Lord Chancellor (Viscount Cave) said that the resolution would not only empower the medical officer of health or a doctor who was a member of the committee to give general advice to married women on the subject of birth control; it would be in the power of any member of the committee, without any medical knowledge and any examination of the person seeking advice, to give her advice. The doctor could not always be there, and were they to allow the other members of the committee, excellent and helpful as they were in many ways, to take the grave responsibility of giving women this advice? The practice that was being discussed was still in the region of experiment. There was much discussion among doctors whether any of the methods recommended were free from danger.

The motion was carried by 57 votes to 44.

Bills.

In the House of Lords, on April 28th, the Midwives and Maternity Homes Bill, which has passed the House of Commons, was read the first time.

I.M.S.—On May 3rd Earl Winterton informed Mr. Lansbury that the Indian Medical Service, being an all-India service, was a central subject, and to safeguard the position of the members of the service it was provided in the Devolution Rules that a local government should employ such number of Indian Medical Service officers in such appointments and on such terms and conditions as might be prescribed by the Secretary of State in Council. Among the posts reserved for the Indian Medical Service under this rule was that of Surgeon-General with the Government of Madras, and one of the conditions prescribed by the Secretary of State in the case of this and a small number of other high posts was that they should be filled by nomination by the Governor-General. The object of prescribing this condition was to safeguard the interests of the service as a whole, and the claims of officers not serving in the particular province concerned.

Registration of Nursing Homes.—The Select Committee of the House of Commons on the registration of nursing homes took evidence on April 29th from Miss Macdonald, secretary of the Royal British Nurses' Association, who advocated the registration of all nursing homes, their inspection, not by local authorities, but by officials appointed by the Ministry of Health, and their staffing entirely by trained nurses, with a housekeeper. Answering Sir Richard Luce, she said it was not common in her experience for nursing homes and maternity homes to be combined. She thought maternity cases should not be in the same homes as septic surgical cases. There should be separate inspecting staffs for nursing homes and for maternity homes. Sir Richard Luce said this was likely to prove a practical political point. Was witness prepared to wreck the bill on it? Miss Macdonald said she was not. Witness proposed that inspection should be by nurses. Sir Richard Luce asked whether the Government would not then require a large staff of inspectors of matrons or at least of sister's standing. Witness did not think that many would be required. Answering Dr. Shiels, she said many of the association members worked in nursing homes, and she had from them many unsatisfactory reports. She knew of a home where five nurses slept in one room. There was not so much complaint now about long hours. Evidence was given by another witness concerning a nursing home where neglect of the patients was alleged.

Telephone Boxes.—On April 27th the Postmaster-General informed Sir H. Brittain that where attendants were employed at public telephone boxes they were responsible for keeping the cabinet and apparatus in a clean condition. The mouthpieces and earpieces were wiped with a clean cloth, moistened with disinfectant, every morning. The floor was washed at least once a week and the inner walls occasionally, as required. At unattended call offices the mouthpieces and earpieces were wiped with a clean cloth and moistened with disinfectant once, twice, or three times weekly, according to the use made of the office. The floor was washed once a week and the inner walls as required. Standard makes of disinfectant were used. On April 27th the Postmaster-General told Rear-Admiral Beamish that rural telephone call offices installed in local post-offices were available only during the hours when the post-office was open, but urgent calls could

generally be made at other hours upon payment of a disturbance fee if there was a responsible person on the premises. Such calls were rare.

Death Penalty for Cowardice in the Field.—In Committee on the Army Annual Act, Mr. Thurlte moved a new clause to abolish the death penalty for all cases of cowardice and desertion on active service, reserving it for treachery and desertion to the enemy. He said there were great differences of physique, nervous system, and will power among men, and it was unfair to take an individual who had been meagrely treated by Nature and subject him to this terrible penalty. Let them contrast the physique and nervous system of a man brought up in the slums, undernourished almost from birth, and subjected to long spells of unemployment, with those of a man from Australia, well nourished all his life and with body and nervous system toned up by an open-air life. The latter must inevitably be better adapted to stand the strain of modern battle. Captain King, Financial Secretary of the War Office, said the Committee which considered the question two years ago pointed out that only 11 per cent. of the death sentences passed during the late war were carried out. Certainly 999 out of 1,000 officers and men who served in that war knew fear. After three years' overseas experience in the war he could count less than ten men whom he knew to be without fear. Some men had less self-control than others, and it was necessary to give a final fillip to their will power. Mr. Attlee said courage failed suddenly, and the man was not then in a position to weigh the consideration that if he went back he would be shot. The death penalty was not a deterrent, but a failure to recognize the psychology of men under modern conditions. Major Hills said that in the Peninsular war when a British regiment had lost 10 per cent. of its effectives that regiment was finished. In the late war a battalion of 500 men might lose 50 per cent. in taking up its position before an attack, but who thought of going back? After losing half its effectives a battalion would still go on. Either the present generation was braver than the generation which fought in the Peninsula, or modern war was less terrible than the old wars. A man who was a coward and wanted to go back from the front line could usually do so. He could always go to the medical officer and say he had a pain in his stomach. He might have that pain or not, but he was a nuisance to his fellows, and his commanding officer was glad to get rid of him, so in the end that man went back. Mr. Viant said some men could not climb to great heights; their nerves would not permit them. The same thing must hold true on the battlefield. The proposed clause was defeated by 269 to 123.

Answers in Brief.

The mid-year population of England and Wales for 1925 is estimated by the Registrar-General at 38,890,000.

Asked, on April 29th, whether he proposed to hold an inquiry into the purity of drugs supplied to panel patients, Mr. Chamberlain said arrangements were in operation for the systematic analysis of sample prescriptions with the object of testing the purity of ingredients and the accuracy of dispensing. He saw no need for the suggested inquiry.

The House of Commons has voted an estimate of £348,200 for expenditure on Employment and Health Insurance buildings in Great Britain, including the Ministry of Health.

Universities and Colleges.

UNIVERSITY OF LONDON.

THE following candidates have been approved at the examinations indicated :

DIPLOMA IN PSYCHOLOGICAL MEDICINE (with special knowledge of Psychiatry).—D. E. Cameron, E. C. T. Emerson, C. O. Perera, J. S. I. Skottow, R. Thompson.

Postponement of Examinations.

The Vice-Chancellor of the University of London announces that the Final B.A. examinations for internal and external students, which were to have been held in June, have been postponed to a date to be announced later. All intermediate examinations; all examinations in agriculture, laws, engineering, commerce, medicine, dentistry, veterinary science; examinations for diplomas. The following examinations for external students normally held in June or July have also been postponed to a date to be announced later: Examinations in commerce, medicine, dentistry, and veterinary science. An announcement will be made later regarding other examinations for external students. The following examinations will be held at the dates given in the regulations: Matriculation and certificate in religious knowledge, general school examination, M.A. and M.Sc. (internal and external), and exhibitions examinations.

NATIONAL UNIVERSITY OF IRELAND.

UNIVERSITY COLLEGE, DUBLIN.

The following candidates have been approved at the examinations indicated:

M.B., B.Ch., B.A.O.—P. H. Cummins (second-class honours), C. F. Carey, J. Coghlan, J. J. Craig, T. Daly, E. R. Devlin, Alico H. Duff, T. Duff, P. Dwyer, J. F. J. Kelly, Kate A. Moran, Marguerite S. O'Mahony, Eileen M. O'Neill, J. L. N. O'Sullivan, K. Phelan, T. J. A. Ryan, J. Vescey, G. J. Waters.

The following are exempted from further examination as indicated;

In Part I (Medicine and Pathology): T. N. Fogarty, J. J. Glyn, E. Kilmartin, Jane A. M. Nagle, T. H. Quinn, J. G. O'Donnell.

UNIVERSITY OF BOMBAY.

THE Bombay University Handbook for the current year contains the provisions of the Acts relating to the University and the general regulations by which it is governed. A list of officers is given for the present and the previous year, and also the rules and regulations of the University library, a list of scholarships and prizes, and the syllabuses of all the various examinations. A list of textbooks for the arts, science, and law examinations is included.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN ordinary quarterly comitia of the Royal College of Physicians of London was held on April 29th, when the President, Sir John Rose Bradford, was in the chair.

Fellowship.

The following were elected to the Fellowship:

The following were members of the Society:

Donald Rose Palmerston, M.D.Ed., (Cardiff), George Eric Campbell
Pritchard, M.B.E.D. (London), Sir John H. Forbes Simon,
K.C.V.O., M.B.E.D. (London), Wilfred Edgewcombe, M.D.Lond.
(Harrowgate), Harold Pritchard, M.D.Lond. (London), Frederick
George Thomson, M.D.Lond. (Bath), William Johnson, M.C.,
M.D.Lond. (Liverpool), Charles Wilfred Vining, M.D.Lond. (Leeds),
Richard Robins Armstrong, M.D.Camb. (London), John Josias
Conynheare, M.D.Oxf. (London), John Cuthbert Matthews, A.F.C.,
M.D.Camb. (Liverpool), Julian Lionel Friston, M.B.Lond. (London),
John Alexander Drake, M.D.Lond. (London), Francis Lister
Sutton, M.D.Ed. (London), Ambrose Thomas Stanton, M.D.
Toronto (Kuala Lumpur), Sir George Seaton Buchanan, C.B.,
M.D.Lond. (London).

Nominated by the Council under By-law XL (b):

Arthur Edwin Boycott, M.D.Oxf. (London), John Thomson, M.D.Ed.
(Edinburgh).

Membership.

The following candidates, having satisfied the Censors' Board, were elected:

W. L. Ackerman, M.B.Lond., H. C. Beccle, J.R.C.P., F. B. Byrom, M.B.Lond., A. M. Cooke, M.B.Oxf., W. E. Cooke, M.D.Liverp., W. S. C. Copeman, M.B.Camb., E. R. Cullinan, M.B.Lond., A. J. Davies, M.B.Birm., C. F. Fernando, M.B.Lond., W. Fletcher, M.D.Camb., H. Fraser, M.D.Aberd., J. F. Fuller, M.B.Oxf., R. N. Hajra, M.B.Calcutta, H. M. Hechinger, M.B.U.Toronto, G. M. Mihli, M.B.Camb., M. Newman, M.D.Liverp., J. B. O'Connell, M.D.Scand., W. Patterson, M.D.Melb., H. V. Pbelon, M.B.Leeds, H. Playfair, M.B.Camb., T. W. Preston, M.B.Lond., T. A. Ross, M.D.Edin., E. B. Strans, M.B.Oxf., H. F. Turney, M.B.Oxf., Gladys M. Wanchope, M.D.Lond., J. Whitby, M.B.Lond., J. F. Williams, M.B.Melb.

Licence.

Licences to practise physic were granted to the following 194 candidates, who have passed the Final Examination of the Conjoint Board and have complied with the by-laws of the College:

M. O. Abdeen, C. E. Allen, *Marion L. Bainbridge, J. C. H. Baird, M. Baror, B. E. Barrett, G. H. Bellorby, P. G. Benfihl, O. E. Biggar, C. R. Birnie, H. B. B. Birt, A. B. Blackall, J. L. Blonstein, W. R. Hunt, D. Borham, *Kathleen M. Bowen, *Maudie, G. B. Bowin, G. J. O. Bridgeman, G. H. Brown, H. Bruce, P. R. Buckton, H. A. Bulman, F. Bunéj, A. Burlingham, C. H. Burridge, H. A. Byrworth, E. Byrne-Shaw, *Elizabeth J. Carpenter, A. G. Chamberlain, G. P. Chandler, J. C. K. Chlicott, *Enid Clarke, S. M. Coleman, A. B. Connell, R. A. P. Corkery, J. G. Cox, *Lucy M. Cranage, G. H. Crisp, *O. R. Croft, B. R. Crossley, *Olive C. Crowley, P. C. Cumber, P. G. Datta, T. L. Davies, J. E. Debono, J. H. de Jager, T. S. Dewey, D. A. Dewhurst, A. F. Downie, I. A. Dubninsky, R. A. M. Dyke, W. G. P. Dyson, R. P. S. Edden, A. G. Edisson, G. Edwards, G. C. Edwards, *M. N. El-Din, E. Evans, E. S. Evans, J. P. Evans, J. A. Eyros, *A. B. Field, R. A. Fitzsimons, A. R. Flower, J. G. F. Ford, *M. Forman, *E. A. G. Giersill, A. R. French, J. Freudenheim, *Margaret L. Galbraith, *J. E. Gillard, R. B. Glennie, L. D. Golomb, J. Gray, R. M. Grosdon, E. J. Greenwood, T. W. Griffiths, H. L. Groom, G. J. Gross, K. H. A. Gross, B. Guyster, A. F. W. Hall, H. J. Heathcote, T. H. Hobbes, A. Hohson, L. F. Houghton, J. E. Howard, *E. G. Howe, M. L. Hutchinson, D. Ingher, F. F. Imiantoff, J. H. F. Jayasuriya, *Iris A. Jenkin-Lloyd, D. McIl. W. Kendall, J. W. Kendall, *Ellecn M. Labor, J. R. E. Lee, H. P. Lehmann, P. O. K. Lewis, L. Lipschitz, G. H. Lipschitz, *Elsie Lyon, *Margaret B. Macdonald, *Mary A. C. MacBugh, R. M. Maher, A. R. Marsh, C. W. Marshall, *Florence J. Masterson, *C. E. Matheis, C. E. McGee, J. E. Miller, H. L. Milles, J. McN. Milloy, D. E. Mitchell, D. Moyle, J. W. Nonro, E. W. Moran, J. A. C. Morton, C. E. H. Moykott, M. Murad, B. L. S. Murtach, A. H. Musgrove, H. P. Nelson, C. B. Netscher, D. A. Newbery, R. Okell, E. R. S. Owen, *Evelyn M. Pakeman, *Marion G. Palmer, S. C. St. G. Parry, W. D. Parry, A. Patrick, P. H. Perkins, E. K. Pritchard, *Henrietta Procter, M. M. Raafn, W. H. G. Reed, J. H. Ripka, M. E. D. Roberts, R. I. Roberts, *Jane McL. Robertson, E. Robinson, *Alice L. Robson, E. H. Roche, *Sybil D. Rodgers, F. C. Roles, R. P. Ross, H. W. Sadlier, J. de la M. Savase, J. W. Schofield, J. W. Schollm, J. A. Seacord, *S. Sambe, *Sendak, *Nancie A. Simmons, F. Sturmon, W. E. Snell, *W. E. Mrs., *Deryl M. Stevens, *Dorothy E. Stewart, E. C. N. Strong, *Mrs., *Deryl M. Stevens, *E. Theis, J. W. de W. G. Thornton, G. P. Thorold, O. T. Thiel, E. M. Town-Jones, *Mary M. Tulloch, W. J. D. Twort, C. C. Ungley, E. F. C. Wadge, H. Walden, F. H. A. Walker, E. Walsh, *Betty C. Waters, T. E. Watkins, J. G. Weston, J. G. Wiley, J. I. Williams, H. Winch, *Elleen C. Wise, W. R. Wood, *Rosa S. Wordsworth, Hon-Ping Yew, H. R. Youngman, A. B. Zimble,

* Under the Medical Act, 1876

Research Prize in Metabolism.

It was reported that the College, had expressed the desire to bestow some £2,000, for research work in disorders of reference for the study of their occurrence in children and adolescents, and particularly for diabetes.

Appointments.

It was announced that Mr. Dighton Pollock has accepted the office of junior standing counsel, and Dr. S. W. Wheaton that of delegate to the Jubilee Conference of the Royal Sanitary Institute in London in July, 1926.

Dr. H. Morley Fletcher was elected Senior Censor.

The President was appointed to represent the College at the celebration of the bicentenary of the Faculty of Medicine of the University of Glasgow on July 11th, 1926.

It was decided to send a Fellow to represent the College at the National Association for the Prevention of Tuberculosis at Glasgow on July 1st, 2nd, and 3rd, 1926.

Sir Humphry Rolleston was elected a member of the Executive Committee of the Cancer Research Fund.

Portrait of the late Sir Richard Douglas Powell.

Sir Douglas Powell, Bt., offered to the College a replica of a portrait of his father, the late Sir Richard Douglas Powell, Bt., painted some thirty years ago by Spencer Watson, A.R.A., the replica to be painted by the same artist. This offer was accepted and the thanks of the College accorded to Sir Douglas Powell.

Conjoint Examinations.

Three reports from the Committee of Management of the conjoint examinations were received and adopted.

The Committee reported that certain restrictions in the new conjoint students as compared with students who are following the curricula of various universities had been made to meet this.

II. In order that the examination in as far as possible to clinical medicine and surgery, an examiner in special pathology will in future be appointed conjointly with the appointed examiner in pathology, and also take part in the practical and *viva voce* examinations. As pathology will cease to be a subject included in the examination in medicine and surgery, the *viva voce* examination in these subjects will be reduced from twenty to fifteen minutes. In this way there will be a *viva voce* examination in medicine of fifteen minutes' duration for each candidate, with the preliminary period of ten minutes for the examination of excreta and of the microscope specimens, while in surgery there will be one period of fifteen minutes' *viva voce* examination instead of two periods of ten minutes.

III. *Examiners in Tropical Medicine and Hygiene.*—Owing to alterations in the distribution of the examination for the Diploma in Tropical Medicine and Hygiene, there will in future be two examiners described as "examiners in pathology and tropical hygiene" and two described as "examiners in tropical medicine and surgery," one of each description to be appointed by each College as at present.

Regulations for Membership Examination.

The Registrar gave notice that at a forthcoming general meeting of the College he will propose, on behalf of the Censors' Board, additional regulations for the Membership Examination, as follows:

Every candidate for the Membership shall furnish proof:

- (1) That he has been engaged in work in a clinical laboratory for a period of at least three months he has received instruction in medicine
- (2) That he has held a house-physician's appointment for a period of at least six months, or some other appointment involving personal responsibility for patients, which shall be considered by the Censors as equivalent.

Tenure of Office of President.

A proposal that the tenure of the office of President should be limited to three years was defeated after some discussion.

Medical News.

THE Prince of Wales has chosen Friday, July 16th, as the date on which he will preside at the dinner in aid of the funds of the National Association for the Prevention of Tuberculosis, which was postponed in December last owing to the death of Queen Alexandra.

WE are asked to remind readers that the complimentary dinner to Sir StClair Thomson, President of the Royal Society of Medicine, arranged by the Section of Laryngology, will be held at the Hotel Victoria, Northumberland Avenue, on Friday, June 4th, at 7.30 p.m. The dinner will be followed by a dance. The price of the dinner and dance, exclusive of wine, is 21s. Tickets may be obtained from Mr. Norman Patterson, 82, Portland Place, W.1.

THE Röntgen Society and the Electro-Therapeutics Section of the Royal Society of Medicine announce that the seventh Mackenzie Davidson Memorial Lecture will be delivered by Dr. A. Danvilier of Paris in the Barnes Hall (1, Wimpole Street) on Thursday, May 20th, at 8.15 p.m. The subject of the lecture is "The measurement of x-ray dosage."

THE Maudsley Lecture will be delivered before the Royal Medico-Psychological Association on Tuesday, May 18th, at 3 p.m., in the Great Hall of the British Medical Association House, Tavistock Square, W.C., by Professor George M. Robertson, President of the Royal College of Physicians of Edinburgh; the title of the lecture is "The prevention of insanity: a preliminary survey of the problem." The President, Sir Frederick Mott, K.B.E., F.R.S., will take the chair. Admission is free without ticket.

THE Fellowship of Medicine announces that the Royal Northern Hospital will give a fortnight's intensive all-day course in medicine, surgery, and the specialties, beginning on May 31st, and the Children's Clinic will start a special three weeks' course on the same date. During June the following courses will also be held: a two weeks' course in chest diseases at the City of London Hospital for Diseases of the Heart and Lungs, Victoria Park; a three weeks' course in gynaecology at the Chelsea Hospital for Women; a course in urology at the All Saints' Hospital three afternoons weekly for a month; a course in bacteriology at Charing Cross Hospital; and a general practitioners' course at the London Temperance Hospital, lasting a fortnight, with daily lectures and demonstrations from 4.30 to 6 p.m. Copies of all syllabuses and of the general course programme may be had from the Secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1.

AT the meeting of the Royal Society of Tropical Medicine and Hygiene, to be held at 11, Chandos Street, W.1, on Thursday, May 20th, a paper on the treatment of surra in India will be read by Mr. J. T. Edwards, B.Sc., M.R.C.V.S., Director of the Imperial Bacteriological Laboratory, Muktesar.

DR. JOHN COWAN of New Galloway, Kirkcudbrightshire, the smallest Royal Burgh in Scotland, has recently been presented with a silver loving-cup from the councillors and others to commemorate the completion by him of twenty-five years as provost.

THE date of the annual dinner of the Harveian Society of London has been altered from June 10th to Thursday, June 17th.

A CONFERENCE on milk in relation to public health will be held in the King George's Hall, Caroline Street, Great Russell Street, W.C., on Tuesday, June 8th, under the presidency of the Minister of Health. The morning session (10 to 1) will be opened by a short address by the chairman, Mr. Wilfred Buckley, C.B.E., after which the reports of public authorities on the present-day conditions of the milk supply will be considered. Dr. Harriette Chick will read a paper on milk in relation to public health, which will be followed by a discussion to be opened by Dr. W. G. Savage. The afternoon session (2.30 to 5.30) will be opened by the Minister of Health. Consideration of suggestions received by the Conference Committee regarding the steps to be taken for the improvement of the milk supply will be followed by a general discussion. Further particulars can be obtained from Miss J. E. Holland, the secretary of the conference, 3, Bedford Square, London, W.C.1.

THE Rockefeller Medical Fellowships for the academic year 1926-27 will shortly be awarded by the Medical Research Council, and applications should be lodged with the Council not later than June 10th. These Fellowships are provided from a fund with which the Medical Research Council has been entrusted by the Rockefeller Foundation. Fellowships are awarded by the Council, in accordance with the desire of the Foundation, to graduates who have had some training in research work in the primary sciences of medicine or in clinical medicine or surgery and are likely to profit by a period of work at a university or other chosen centre in the United States before taking up positions for higher teaching or research in the British Isles. A Fellowship will have the value of not less than £350 a year for a single Fellow, with extra allowance for a married Fellow, payable monthly in advance. Travelling expenses and some other allowances will be made in addition. Full particulars and forms of application can be obtained from the Secretary, Medical Research Council, 15, York Buildings, Adelphi, London, W.C.2.

AN election to Beit Memorial Junior Fellowships will take place in July. The Fellows then elected will be required to begin work on October 1st. The Fellowships are of the annual value of £350. The usual tenure is for three years. Applications must be received on or before June 1st. Forms of application and all information may be obtained by letter only, addressed to Sir James K. Fowler, honorary secretary, Beit Memorial Fellowships for Medical Research, 35, Clarges Street, London, W.1.

MR. RICHARD LAKE, F.R.C.S., Geoffrey E. Duvenc lecturer in otology in the University of London, and surgeon to the Ear, Nose and Throat Department at University College Hospital, will give three lectures during June on Thursdays at 5 p.m., at University College Hospital Medical School—the first (June 3rd) on deafness and occupations, the second and third (June 10th and 17th) on middle-ear disease. The lectures are open to all practitioners and to medical students.

THE Board of Education has published a new edition of the list of certified special schools, recognized institutions for the training of blind and other defective students, and nursery schools in England and Wales included under its special services regulations. The pamphlet also contains information about certain technical classes for defective students. The schools for physically defective children are divided into groups as far as possible, so as to indicate the type of case dealt with. The addresses of the schools are given, and particulars of the average attendance at each during the year 1924-25. The list may be obtained from H.M. Stationery Office, Adastral House, Kingsway, W.C.2, price 1s., postage 1d.

THE thirty-fifth annual report of the Nurses' Co-operation indicates satisfactory progress during 1925. The number of cases attended increased and the fees paid are larger than those of the previous year, in spite of there having been a smaller number of nurses on the staff. The Nurses' Co-operation was established to provide fully trained hospital nurses and to secure full remuneration for them. It has a sickness benefit fund and a benevolent fund, and nurses are insured against accidents.

DR. J. GLAISTER, of the Inner Temple, was called to the Bar on April 28th.

A TUBERCULOSIS congress will be held at Düsseldorf, under the presidency of Dr. Ziegler of Hanover, on May 28th and 29th, when the following subjects will be discussed: (1) The chemotherapy of tuberculosis, introduced by Drs. Feldt of Berlin and Urieel of Charlottenburg. (2) The modes of dissemination of tuberculosis, introduced by Drs. Bruno Lange of Berlin and Beitzke of Graz.

DR. LAIGNEL-LAVASTINE has succeeded Professor Menetrier as president of the Société française de l'histoire de la médecine.

MESSRS. PICKFORDS, LTD., 206, High Holborn, London, W.C.1, are issuing a programme, which can be obtained from any of their branches, entitled "Holiday Tours, 1926." They have arranged for motor tours, both in Britain and on the Continent, and we are asked to state that the baggage of passengers booking Continental tours through them is automatically insured to the value of £50 for the duration of the holiday.

UNDER the name of Journées médicales de Paris a congress of an essentially practical nature, appealing to all branches of the profession, will be held in Paris from July 15th to 19th under the presidency of Professor Fernand Vidal. There will be an exhibition at the same time of books, instruments, drugs, etc. Excursions are being organized to Rheims, the battlefields of Champagne, and hydromineral spas. The subscription will be 50 francs for practitioners and 20 francs each for members of their family. Further information can be obtained from the general secretary, Dr. Dujarric de la Rivière, 18, rue de Verneuil, Paris.

THE thirty-first Dutch Congress of Public Health will be held at Utrecht on June 25th and 26th, when the following subjects will be discussed: (1) The risk of tuberculous infection in various occupations, introduced by Drs. R. N. M. Eijkel and M. K. Huijsins van der Berg. (2) The value of terminal disinfection in infectious diseases, introduced by Dr. L. Heijerins.

THE Oriental Medical Association, like the British Medical Association, has this year started a new *Oriental Journal of Diseases of Infants*. At the end of 1922 Dr. Suzuki of Kyoto, Japan, founded the *Journal of Oriental Medicine*, which has become so popular with Japanese contributors that papers on infant disorders have been crowded out. Hence the new journal, of which Dr. Suzuki is editor. The first number is a tribute to Professor I. Hirai, who attained his sixtieth birthday on October 31st, 1925. Professor Hirai was the founder of the children's clinical section in the Kyoto Imperial University. He has contributed much to the literature of pediatrics, and has in particular elucidated the nature of serous meningitis in infants, a disease which causes a high mortality in Japan. He is now succeeded by Dr. Suzuki. The first issue contains seven papers, two in English and five in German, as well as a Japanese section. Of the papers the first and longest is in English; it is on congenital bone syphilis, is written by the editor, and is profusely illustrated by skiagraphs. The second paper also is in English; it is on the control of beri-beri, and is by two medical officers of the Manchurian Plague Prevention Service—Dr. J. W. H. Chun, senior medical officer, and Dr. Wu Lien Teh, director and

chief medical officer. They insist on the importance of obtaining legislative and educational measures, and point out that the two in fact overlap, but consider the latter the more important. They lay particular emphasis on the value of vitamin-containing foodstuffs, such as fresh vegetables, beans, sprouts, and fresh fruit. If these are consumed in sufficient quantities, they say, beri-beri may be avoided, even though white rice is eaten. They attach more importance to education than to legislation because the latter may have the effect of increasing the cost of living. The papers in German are short; two of them deal with child dysentery and two with pneumonia. The new periodical is to be published quarterly by the Children's Clinic of the Kyoto Imperial University. No price is mentioned.

Minerva Medica, which is devoted to the early diagnosis of cancer, has recently published original articles by the editor, Professor F. Micheli, on the serum diagnosis of cancer, by Professor Monpurgo on histological diagnosis, by Professors A. Carle and G. M. Fasiani on early diagnosis of cancer of the breast, and by various specialists on the early recognition of cancer in other parts of the body.

DR. JEAN CHARCOT, who was recently elected a member of the Académie des Sciences, has been awarded the prize of 100,000 francs founded by Prince Albert I of Monaco in recognition of his numerous scientific expeditions and as a grant for the oceanographic researches which he will shortly undertake.

ON the occasion of the fiftieth annual meeting of the German Society for Surgery the issue of the *Zentralblatt für Chirurgie* of April 10th published a series of letters addressed to von Langenbeck the founder, and Gurit, for many years secretary of the society, by numerous well known German surgeons, including von Bergmann, Billroth, Esmarch, Thiersch, Hagedorn, and Volkmann. A brief account of their life and works has been prefixed to the letters by Dr. August Borchard, one of the three editors of the *Zentralblatt*.

PROFESSOR S. NIKANOROV, director of the Institute of Microbiology at the Saratov Faculty of Medicine, has recently been awarded the decoration of the "red flag of work," which is the highest distinction in the Union of Soviet Republics.

COMMENTING on the fact that neither the German Ophthalmological Society nor the German Society for Gynaecology will hold a congress this year, the editor of the *Deutsche medizinische Wochenschrift* expresses the hope that many other societies will follow their example to prevent the excess of scientific publications in general and of congress proceedings in particular.

A FURTHER series of articles, entitled "Occupation and Health," have been issued by the International Labour Office as part of the *Encyclopaedia of Hygiene, Pathology, and Social Welfare*, which is being compiled. The present series, Nos. 22-29, relates to poisonous woods, calcium cyanamide, the superphosphate industry, ankylostomiasis, the rubber industry, asbestos, the felt hat industry, and methyl bromide. When the whole series has been published the complete *Encyclopaedia* will be issued in a bound volume.

THE annual report for 1925 of the National Baby Week Council shows that about 500 local baby weeks were arranged during the year, and that there was an increasing tendency for local authorities to undertake continuous propaganda by film displays, lectures, and demonstrations. Many local health weeks also devoted much attention to questions relating to welfare work. Accounts are given of the various competitions arranged by the Council during the year. We referred to some of these a few weeks ago when mentioning (p. 461) the annual general meeting early in March.

THERE has recently been an increasing number of cases of rabies throughout Germany, 44 municipalities having been attacked in Lower Franconia, 23 in the Upper Palatinate, and 18 in Lower Bavaria. A serious outbreak of anthrax due to contamination of the pastures has occurred in Omsk, Siberia.

THE jubilee of the Association pour l'Avancement des Sciences will be celebrated at the 1926 congress of the association, which is to be held at Lyons from July 26th to 31st. A large scientific exhibition has been organized in connexion with the congress, with pharmacological, radiological, psychological, and other medical sections.

A HYDROBIOLOGICAL station has recently been established on the Danube at Vienna under the direction of Dr. A. Czerny.

DR. FERNANDO CASADESÓ has been nominated professor of oto-rhino-laryngology in the Barcelona Faculty of Medicine.

THE seventh Italian Congress of Radiology will be held at Naples next October.

THE graduation dinner of the University of London, which was to have been held on May 12th, has been cancelled in consequence of the strike.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and **LETTERS** forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring **REPRINTS** of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to **ADVERTISEMENTS**, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9361, 9362, 9363, and 9364** (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR of the **BRITISH MEDICAL JOURNAL**, *Aitology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumshugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

QUERIES AND ANSWERS.

"R. S. F." asks for advice on the treatment of a man, aged 60, who has had a urethral stricture for ten years. He is unable to micturate normally, and has been passing a No. 9 gum elastic catheter twice a day. As the stricture readily admits a No. 11 sound, the disability would appear to be of nervous origin.

"E." asks for advice in the treatment for the following case: A woman with lipomatosis of both legs round the ankles, more marked in the right leg. There is thickening round both ankles and the underlying fatty tissue is attached to the skin. No other collections of fatty tissue are present elsewhere.

NON-OPERATIVE TREATMENT OF CONGENITAL PYLORIC STENOSIS.

DR. J. L. MEAGHER (London) writes:—Bearing upon my article published in the issue of January 16th upon the non-operative treatment of congenital pyloric stenosis, a letter which I received recently from Professor H. Finkelstein, director of the Kinderkrankenhaus of the municipality of Berlin, is of interest. In it he states: "We have treated since your being with us about ten cases in the same manner with equal success. Only one has been operated on." For the information of those who have not read the article it may be mentioned that the chief points of the treatment practised at the Kinderkrankenhaus are atropine and adrenergic medication, concentrated feeding, and stomach wash-out.

HYPERTHERMIA.

DR. E. THORP (Assistant M.O.H. Sunderland) writes with reference to the query on hyperpyrexia (March 20th, p. 554): I have seen hyperpyrexia in acute rheumatism and puerperal sepsis, in each case the normal thermometer being useless. I had no difficulty in procuring a hyperpyrexia thermometer for my hospital for such cases. A case in which the temperature reached 109.6° F. is recorded in *Clinical Notes and Deductions of a Peripartetic*, and another in the Ministry of Health's book on encephalitis lethargica as having occurred in Sunderland Royal Infirmary (114°). The highest temperature I myself have seen is 112°, in puerperal sepsis, and 114° in the same case shortly after death.

THE ERADICATION OF COCKROACHES.

IN reply to a correspondent, who asks how cockroaches may be eradicated from the ground floor (kitchen and offices) of a house, we may say that the first step to be taken is to seal up all cracks in which they can live, special attention being paid to cracks round fireplaces, entrances of pipes, and the backs of cupboards. The skirting should also receive attention. The most satisfactory method of attacking the cockroaches is to use some insect powder, such as one of the following: (1) Sodium fluoride 3 parts, and fresh pyrethrum powder 1 part; (2) powdered borax and pyrethrum, with a little sugar added; (3) plaster-of-Paris 1 part, and sugar 2 parts. These three mixtures are all harmless to animals and are all very effective against cockroaches. Whichever powder is preferred, it should be scattered about the spots where the cockroaches are found at night and the dead swept up in the morning; its use must be persevered with for some time. All foodstuffs should, of course, be kept out of the way or the cockroaches will be induced to eat the powder. Poisoned pastes are not recommended, unless there is no possibility of children or animals reaching them. Traps, consisting of jam jars with a cardboard lid containing a hole in the middle, may be used. Through the hole an inverted paper cone with an apical

opening should be inserted. The insects enter through this to reach the contained bait (beer or banana is excellent for this purpose) and are unable to escape. Sulphur dioxide (2 lb. of sulphur per 1,000 cubic feet of space) and carbon bisulphide have also been used for fumigation against these pests with excellent results. We have no records of formalin vapour having been used, but we know of no reason why it should not be successful. If carbon bisulphide is used it is well to remember that the vapour is inflammable and forms an explosive mixture with air. Steam vapour also gives excellent results.

LETTERS, NOTES, ETC.

A MEMBER living in Northampton has asked the Medical Insurance Agency (B.M.A. House, Tavistock Square, London, W.C.1) for particulars of an "All-in Policy" of household insurance, but has not given his full name and address.

A WARNING.

THE Secretary of the Medical Defence Union informs us that the person referred to under this heading in the **JOURNAL** of May 1st (p. 814) has been arrested by the police.

MOTOR CAR INSURANCE.

MR. L. FERRIS-SCOTT, F.C.A., Secretary of the Medical Insurance Agency, writes: With reference to Section 2 (Accidental Damage) of the third clause of the Doctors' Special Policy issued by Lloyd's underwriters through the Medical Insurance Agency, the meaning of the words "and shall also indemnify the insured in respect of external damage to the insured car during riots and civil commotions" is undoubtedly that damage caused to any part of the car by external means is covered. It will be understood that mechanical breakdown is not covered either during riots or civil commotions or during peace time. Such damage as (1) removal of carburettor, (2) puncture of petrol tank, (3) slashing of tyres, (4) damage to glass, etc., of covered cars, is insured under the policy. If a car is not used for its normal purpose the policy will be invalid unless previous notice has been given and the assent of the underwriters obtained. Thus, a four-seater car could carry four passengers even though they be not personally known to the owner and the policy would remain in full force, but a private car is not normally used for the conveyance mainly of foodstuffs. Damage to springs due to overloading is not covered under the policy, whatever the cause of it. Such damage would come under the "breakdown" and would not be covered. It should be noted that the holders of policies usually covered for damage by fire and by riots and civil commotions are the same remark applies to "combined" policies. It would be wise, therefore, for all insured householders to see that they hold "comprehensive" household policies of the type issued through the Medical Insurance Agency, in which case they will find their interests fully protected in the terms of the policy.

PERSONAL CLEANLINESS: LATRINES.

do not exist; most toilet papers are not impervious, and when the extent to which our food is handled is taken into consideration it becomes a matter of surprise that gastro-intestinal disorders are not more common.

THE AFTER-TREATMENT OF OPERATION CASES.

"PHYSICIAN" writes: It is generally recognized that the after-treatment of operation cases is of great importance, and surgeons who have not the time to attend carefully to the after-treatment of patients on whom they have operated at nursing homes usually leave it in the hands of a competent junior surgeon. But unfortunately this is not always done. Thus, at a large well known London nursing home, on requesting not long ago that a patient under treatment there might have the dressing advised by the surgeon who had operated, I was informed that the nursing staff acted as house-surgeons and would not think of asking the surgeon what further dressing should be applied. This statement may only have been a silly boast, but, if true, no doubt it is exceptional for the nursing staff to act as house-surgeons in other nursing homes. Nevertheless, I have good grounds for believing that in some private nursing homes in many cases the dressings and after-treatment of operation cases are left too much in the hands of nurses, often to the detriment of the patient. After very sad experience I consider it is clearly the duty of physicians and general practitioners, before placing their operation cases in the hands of any surgeon, to ascertain, if possible, who will carry out the after-treatment and dressing. If this will be left chiefly in the hands of the nurses, then my opinion is that the assistance of some other surgeon should be obtained.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 34, 35, 36, 37, 40, and 41 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 38 and 39.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 184.

A Post-Graduate Lecture ON CARDIO-AORTIC SYPHILIS AND ITS TREATMENT.*

BY

THOMAS F. COTTON, M.D., M.R.C.P.LOND.,

PHYSICIAN TO OUT-PATIENTS, NATIONAL HEART HOSPITAL; CONSULTING
CARDIOLOGIST, MINISTRY OF PENSIONS.

SYPHILIS of the aortic orifice is, I think, considered to be, in male adults, the most common cause of aortic insufficiency. The disease of the heart is so frequently associated with syphilis of the aorta itself that, from a pathological standpoint, it is not justifiable to consider the two conditions separately. Whether the aortic valves are ever primarily and exclusively attacked by syphilis—true syphilitic endocarditis—is still an open question. The pathological changes in the aorta are those of syphilitic mesoarteritis. Microscopically, the most important changes found in the media and adventitia are a perivascular infiltration of the vasa vasorum, with small-cell infiltration in areas of the media, and a splitting and destruction of elastic fibres and the muscle cells. The heart muscle shows hypertrophy more in the left ventricle than the right, and dilatation. The hypertrophy is much like that seen in the patient with hypertension. Spirochaetes are often found in the walls of the aorta and heart muscle. The normal structure of the valve area is altered so as to produce insufficiency at the orifice during diastole. The picture in most cases is that of aortic insufficiency, and not of aortic stenosis. The valve leaflets are sclerosed and retracted and sometimes there is marked sagging, and there may be actual destruction of the leaflet. The free margin of the valve may be greatly thickened and rigid. General arteriosclerotic changes of the aorta may be noted, and complete or partial occlusion of a coronary orifice.

SYMPTOMS AND CLINICAL COURSE OF THE DISEASE.

If we analyse the symptoms of a large group of syphilitic aortics, some 200 in number, which we have had under continuous observation for a number of years in the cardiac clinic of Sir Thomas Lewis at University College Hospital, nothing really distinctive will be found to distinguish this group from another group, also under observation during a similar period, with aortic disease of rheumatic origin. A certain number, sooner or later, had symptoms of heart failure with congestion—breathlessness at rest, and the other symptoms which we are accustomed to associate with pulmonary congestion, hepatic engorgement, and other signs of increased pressure in the venous system. The onset of auricular fibrillation with a rapid ventricular rate may be the direct cause of failure in a proportion of these cases. A normal rhythm is, however, the rule. A few have subacute infective endocarditis. A second larger group had symptoms due to loss of cardiac reserve, but with the myocardium not sufficiently damaged to cause venous stasis; they had breathlessness on slight exertion, precordial pain, palpitation, giddiness, fatigue, and undue exhaustion. There is a third group, much smaller than one would expect, the chief complaint of which is pain that is anginal in character and distribution. There is, too, a small hypertension group, often, but not always, with albumin and casts in the urine. Finally, we have to consider a small number who have signs of aortic disease but no obvious symptoms of myocardial insufficiency.

The aortic arch will be found dilated in many patients with aortic regurgitation of syphilitic origin, but in not a few such aortic widening will be absent. It should, of course, be suspected in all cases of frank aortic syphilis, or where syphilis is suspected as the cause of the disease. Those with aortic dilatation and hypertension tend to fall into the anginal group, though the anginal syndrome may be absent; while in many with angina the blood pressure may not be raised. One cannot, however, say that the greater the dilatation, the nearer such dilatation becomes aneurysmal, the more frequently will it be found that the

type of heart failure is anginal in character. When an aneurysm is present the symptoms complained of may be due to pressure of the aneurysm on the surrounding tissues. Aneurysm of the transverse arch is more likely to give rise to these symptoms than aneurysm of the ascending arch. Symptoms may lead us to suspect cardio-aortic disease, but it is upon physical signs that we must rely in arriving at a diagnosis.

PHYSICAL SIGNS OF THE DISEASE.

The physical signs of cardio-aortic disease of syphilitic origin are in some cases those signs we associate with heart failure of the congestive type—that is, signs of pulmonary congestion, with engorged veins in the neck, hepatic engorgement, renal congestion, etc. There is nothing in this type of failure which indicates the syphilitic origin of the disease. Identical signs occur in aortic disease of rheumatic origin. All degrees of enlargement are seen, from the heart which is normal in size to dilatation and hypertrophy extending past the anterior axillary line. The signs of valve disease are those of aortic insufficiency—a diastolic murmur heard over the aortic cartilage. This valve defect in some can only be recognized by listening carefully to the left of the sternum at the level of the third interspace, and sometimes the patient must be placed in a horizontal or left lateral position and the murmur listened for at the end of expiration. This aortic leak may be slight or considerable, and this is determined by the character of the pulse. A collapsing pulse is a sign of free aortic regurgitation. The leak is probably slight when the pulse is not of the Corrigan type. In many patients with the pulse collapsing—that is, with free aortic regurgitation—a presystolic rumble is heard at the apex. It is safe, in the absence of a rheumatic history, to treat this as a Flint's murmur. This murmur may be accompanied by a thrill over the mitral area. Aortic stenosis can be diagnosed when, along with a systolic murmur and most frequently a diastolic murmur as well, a systolic thrill is felt over the aortic cartilage, and the pulse is slow rising, of the anacrotic type. The signs of aortic dilatation are visible palpable pulsation, in the second or third interspace to the right and left of the sternum, submanubrial dullness, and impaired resonance on percussion over the area of pulsation. Aortic dilatation should be suspected when submanubrial dullness alone is present. Always when possible the diagnosis of aortic dilatation or aneurysm should be confirmed by x-ray examination of the chest. It is humiliating when an aneurysm presenting no clinical signs looms up on the fluoroscopic screen, and disconcerting when the x-ray picture reveals a normal-sized aorta when an aneurysm has been suspected. A normal rhythm is present in the majority; auricular fibrillation in a few; extra-systoles are common. Sometimes subacute infective endocarditis completes the clinical picture. There were very few of these cases in this series.

EFFECT OF SPECIFIC TREATMENT IN CARDIO-AORTIC SYPHILIS.

Certain interesting facts emerge from the study of the after-histories of pensioners and ex-service men with aortic syphilis, whom we have kept under observation during the past five years. Of these men referred to the special heart clinic at University College Hospital from the Ministry of Pensions an unselected group of 58 was chosen and given special treatment, and accurate notes were made of the results obtained. An approximately equal number of control cases was selected, closely resembling in age, symptoms, and signs, the group of treated cases. The object of this investigation was to determine if possible the effect on the course of the disease of specific treatment in cardio-aortic syphilis. Since 1919-20 the treated cases were given each year a series of six to eight intravenous injections of novarsenobillon 0.6 gram at weekly intervals. An initial dose of 0.3 gram was given before beginning treatment as a safety measure. These injections were always made in the out-patient department, and no special precautions were taken regarding diet or rest. No accidents have been recorded and no symptoms of consequence developed as the result of treatment. It was felt that 0.3 gram was too small a dose to be of any therapeutic value, and 0.9 gram

* Given at the National Heart Hospital, January, 1926.

too large to give to patients with cardio-aortic syphilis in an out-patient department. A few patients complained of breathlessness after the injections; these were of a nervous type, and no attention was paid to this symptom. Others felt giddy and some fainted, but these gave a past history of giddiness and syncopal attacks. These symptoms were looked upon as vaso-vagal in origin, and not an indication to discontinue treatment. Mercurial inunctions were prescribed at each monthly out-patient visit, and the patient was instructed how to apply the ointment. The majority were given mercury in this way. Some were directed to take hydrarg. eum creta, 1 grain thrice daily, in place of the inunctions. Rarely were symptoms of mercurial intoxication recorded. Potassium iodide, 10 grains thrice daily, was given to all. General tonics were substituted for the mercury and potassium iodide in the control cases, and novarsenobillon was withheld from them. No appreciable change in the physical signs or symptoms in these patients could be detected as a result of treatment. Some felt better; others not. The murmurs remained unaltered, and the size of the heart unchanged. The Wassermann reaction—positive in all—became negative in 12, and all

Chart showing the age incidence of the disease (continuous line), and the ages of those who died (broken line), in two groups of cases of cardio-aortic syphilis—treated (58 cases) and untreated (56 cases). The average age incidence of the disease was: treated cases 46.8, untreated cases 46.9. Of the treated cases 14 died, the average age at death being 45 years; of the untreated cases 19 died, the average age being 45 years.

this reason the ages in the treated and untreated cases are approximately the same. The dotted lines represent the age incidence of death. It will be seen from these curves that the average age at death in the treated cases is 45 years, and in the untreated cases 43 years—a difference of two years. Of the treated cases 14 (24.1 per cent.) have died, and of the untreated 19 (33.9 per cent.)—a difference of 9.8 per cent. A difference in the death rate of 10 per cent. over a period of five years may not be without some prognostic significance. If two years have been added to the life of those patients in the treated group over a period of five years' observation, it is possible that the arrest in the disease was due, at least in part, to the treatment which they received. In both groups deaths occur at a lower age level than the average age of all patients in the series under observation. The numbers in this chart are too small, I think, to allow one to draw further conclusions as to the value of specific treatment in aortic syphilis.

In the table I have given a general survey of the type of cases which make up the two groups of cases under observation. It also displays the relative frequency of deaths in the two groups. The mortality is naturally higher in the group with congestion. Five of these were treated

but one of these are living; this reaction was incompletely positive in one after treatment. In 66 cases there was a definite history of syphilis; the average time since infection in these was twenty-four years. In one case, a man aged 72, syphilis at the age of 18 was admitted. The youngest, aged 36, died of infective endocarditis and gave a history of a syphilitic infection four years before.

The accompanying chart is a graphic representation of the age incidence of the disease in the two groups, treated and untreated, and the ages of those who died. In selecting controls the age of the patient was considered. For

Survey of the Type of Cases in the Two Groups under Observation (Treated and Untreated).

SIGNS.	TREATED. (55 cases; 14 dead.)			UNTREATED. (52 cases; 18 dead.)		
	Aortic Regurgitation: Syphilis.			Aortic Regurgitation: Syphilis.		
	Aneurysm.	Aortic Dilatation.	Nil.	Aneurysm.	Aortic Dilatation.	Nil.

and two died (40 per cent.). There were 3 in the untreated group and all died. The numbers are too few to enable a statement to be made as to the value of treatment when signs of failure with congestion are present. When signs of congestive failure were present it was felt that the disease had advanced too far to expect any improvement in the condition of the patient from specific treatment. It was also considered to be not without risk to treat this type of patient with injections of arsenic. In the treated group without congestion there was one aneurysm with the heart moderately enlarged; this patient is alive, as against 4 with aneurysm, the heart much enlarged in 2 and moderately or slightly enlarged in 2; 3 of these died. It is unfortunate that this incidence of aneurysm is so high in the untreated cases without failure. It might be thought advisable to exclude these 5 cases from the series. Before doing so we must recognize the difficulty of distinguishing between dilatation and aneurysmal dilatation. The line of demarcation is not an easy one to follow. When we consider the next group, with aortic dilatation, we find 27 among the treated and 14 among the untreated, with considerable enlargement of the heart in 7 of the former and 9 of the latter; 8 in the treated group died, and 3 in the control group. Here it might be said that we are dealing unfairly with the treated cases, for on account of the larger number of patients with aortic dilatation in the treated group we might expect the number of deaths to be higher. In the third group—22 treated without dilatation of the aorta, and 8 of these with the heart much enlarged, as compared with 31 controls and 4 with the heart much enlarged—4 of the treated group died, and 9 of the untreated.

Everything considered, the grouping on physical signs is fairly evenly distributed among 56 control and 58 treated cases: 14 of the treated, or 25.4 per cent., died, and in all but one of these treated cases the Wassermann reaction remained positive, as compared with 18, or 34.6 per cent.—that is, the mortality rate is 9.2 per cent. lower in those patients who received specific treatment as compared with patients from whom such treatment was withheld. In the table I have not included 7 cases noted in the chart, as they had no valvular disease.

CONCLUSIONS.

I think it justifiable to conclude from these observations that specific treatment is indicated in syphilitic cardio-aortic disease; that no danger is attached to the intravenous injections of arsenic in moderately large doses given without any special precautions; and that arrest in the disease, as shown from the after-histories of cases treated, may be due to specific treatment given over a period of five years.

A British Medical Association Lecture ON MENTAL INEFFICIENTS: TREATMENT OR PUNISHMENT.*

BY
W. A. POTTS, M.A., M.D.,

PSYCHOLOGICAL EXPERT TO THE BRIDGEMAN JUSTICES; LATE RESIDENT
MEDICAL OFFICER, YORKSHIRE EAST RIDING MENTAL HOSPITAL.

THE subject with which I am dealing is a very big one; it can be approached from many different angles. In the time at my disposal it will be possible to deal only with a few of the problems involved.

The first idea I want to put before you is that the interesting reports published in recent years by the Prison Commissioners show how much their attitude has changed towards crime and delinquency. The observations which have led to this change have influenced, not only those responsible for the care of persons who have proved themselves to be asocial or antisocial, but also the majority of serious thinkers and others interested in social welfare, particularly magistrates, teachers, and ministers; I would mention particularly women workers, whose maternal instinct has made them ready to accept the idea that, in many cases of delinquency, treatment rather than punishment is not only more just, but also holds out greater possibilities of protecting those who require care and protection, and of educating and training many who are of no service to the community at the moment, but are yet capable under guidance of developing into useful citizens.

The thoughts which have led to this change of attitude about delinquency must have been simmering for many years; the first important step in crystallizing out the facts was taken by the late Dr. Charles Goring in the early years of this century. Dr. Goring was a prison medical officer who had before him the theory championed by Lombroso, an Italian authority on mental disease, which was largely accepted at that date—that there is a distinct criminal type, which can be picked out by anatomical configuration and general make-up. Goring, by laborious work during several years, dispelled the illusion that there is a criminal type. He proved that the criminal is just like other men, except that he tends to be a little inferior, physically and mentally, compared with his fellows. He showed that the criminal can never be recognized as such, and should not be branded as a born criminal. The offender is of the same clay as other people. It is impossible, Goring said, to diagnose as such the criminal, who comes from every class and group in the community; all that can be done, if it is desirable to recognize prospective criminals in any group, is to examine that group thoroughly and find out the most inferior, physically and mentally. The most inferior in those respects may become delinquents. At the same time, it may be said of those who take a good place in the group, either physically or mentally—and especially in both respects—that it is extremely unlikely they will ever be found in prison. Delinquents come from every class, however the classes are divided. Suppose they are divided into rich and poor; there are not many rich people in prison because the poor are the most numerous class, and also because, looking at the problem from one angle, poverty is a predisposing factor to crime, stealing being the most frequent crime. But rich people do get convicted; those who do are the most inferior of the rich, physically and mentally, taking the word "mentally" in its widest sense. So with the poor; it is certain the better types of the poor will never be found in prison. Goring's investigations, as he himself saw, inevitably paved the way to the idea that individual examination and investigation is essential.

At the same time it was being recognized more and more clearly that severe punishment is not necessarily followed by less crime. The old theory was that by increasing punishment discipline could be enforced. But we all know that punishment is much less severe now than it was eighty or a hundred years ago; yet crime is steadily diminishing.

The objector may say that there must be some other explanation, such as better education. But if he says that he is really saying that education is one of the most successful remedies for delinquency. Again, it is a matter of observation that the habitual offender, who usually gets a more severe sentence each time he commits an offence, so far from being restrained by the extra punishment, often goes on to commit worse offences and to commit them more frequently.

The natural consequence of such observations, and of Goring's investigation, was the publication in 1915 of a book on delinquency by Dr. William Healy, an American, who started work in Chicago and later transferred to Boston. His book, *The Individual Delinquent*, was epoch-making. But I should now advise the serious student to devote his attention to a more recent and better book, published in this country by Mr. Cyril Burt, *The Young Delinquent*. The young delinquent must always interest us most, because he is the person most likely to respond to treatment. Goring proved that the habitual offender nearly always begins his criminal career between the ages of 16 and 19. My opinion is that if Goring had had the opportunity of examining persons under 16, as I have, he would have placed the determining age earlier; 9 or 10 is a more important age. It is, therefore, a mistake to dismiss the first offender, or a case in the children's court, without full investigation. Inquiry would often show that such a person has been on the wrong path for years, and that what appears to be an unimportant phase may actually be the last opportunity for real help.

If treatment, rather than punishment, is to be the aim, the question arises, What treatment? The answer is, It is only possible to tell by individual examination. In order to be clear about the difference between the old and the new ideas, I would say the old idea was—tell me the crime, and I will tell you the punishment. The new idea is—first tell me all about the individual, including what he has done, and especially his environment, and his training, or lack of training; secondly, let me examine him (a) physically, (b) intellectually, (c) psychologically; then, and then only, can I tell you what treatment he requires.

At this stage we must be careful not to develop any delusions that by suitable treatment we are going to reform every case. We hope to do better than with the old methods, but we must admit that some cases are beyond treatment, and that, even with the most hopeful, disappointments are inevitable. Those who are beyond control must be dealt with by segregation, alike in their own interest and also for the safety of the community. The mentally defective are obviously in the impossible group. It must be admitted at once that in consequence of the inborn nature of mental defect none can be cured, while only comparatively few, after having once gone wrong, can be trained to such a degree that they can ever again lead a satisfactory life in the ordinary world. In order to realize these facts it must be remembered that all the organs of the body consist essentially of cells, embedded in a matrix. The brain differs from all other organs in that its cells, once they are developed, a process which is completed during the few months succeeding birth, never change again. In other organs cells are continually dying and being replaced by fresh ones. In the brain no such change is possible. Besides, the brain cells of a mental defective are obviously fewer, and also smaller and less well developed than in the normal. So the unfortunate defective has to carry on all his life with a supply of brain cells inferior in quantity and quality.

The number of mental defectives found among delinquents, or in prison, is not large. The number in prison in recent years, as recorded by Dr. East and other competent authorities, does not exceed from 3 to 5 per cent. Although only a small group this is an important one, because the mental defective is likely to go on committing offences time after time, as he can be but little influenced either by punishment or by moral training. It is important to remember that high-grade feeble-minded cases are so difficult to recognize that they can only be diagnosed by qualified practitioners who have had some years' experience. The examination must be made under satisfactory

* Given at a meeting of the Brighton Division on March 16th, 1926.

conditions, and can never be made in court; yet it is not infrequent for magistrates to attempt to decide the matter for themselves by a question, such as "Do you know your multiplication table?" or to request the medical expert to demonstrate by a few questions that the person is feeble-minded. It should be pointed out that any examination in court is unfair to the delinquent, and shows complete misunderstanding of the situation.

Individual examination can only be available for a limited number of persons charged at the courts. Examination must be thorough, and must be made by a reliable expert; the time required and the dearth of competent examiners means that only selected cases can be examined. Undoubtedly, more medical experts will be available when there is a demand for their services; so far, however, those who have devoted special attention to the matter have not been encouraged either in court or elsewhere. It is essential to concentrate on the first offender, and especially the young, particularly children. But even in the children's court only a small number can be medically examined; the cases must, therefore, be selected. Who is to select them? Personally, I do not believe in a medical assessor sitting in court, which, as I have already said, is not a place for any medical examination. The cases to be investigated must be selected by the magistrates and the court officials, but we, who know, ought to guide them in the matter. As a rough and ready guide in the case of young delinquents I would say that all the following require careful examination and consideration:

1. Stealing £1 or more, or articles of corresponding value.
2. Offences dangerous to the public, such as placing sleepers on the railway line or throwing stones at passing trains.
3. All sex offences, because it has been shown that a large proportion of such offenders are either mentally defective or suffering from some mental disorder.
4. All who look ill or who are suspected to have any physical defect or disease.
5. All who are suspected of mental defect or mental disorder.
6. Lastly, all those offenders who are not understood.

In regard to the last group it seems extraordinary that it should still be not uncommon to see in the papers that a magistrate has said to an offender: "I cannot understand your case, but I am going to deal with you." Would it not be a help to the magistrate in such circumstances to call to his aid someone who has made a special study of the relationship of delinquency to mental and physical abnormalities? When examining it is necessary first to exclude the mentally defective, because, although not a large class, they are an important one. Next it is essential to pick out any who are suffering from actual mental disorder. This is an even smaller group than the mentally defective, contributing not more than 1/2 per cent., but it is a group which must receive special consideration because the members of it may be a serious danger to the community. It is important to bear in mind the possibility of encephalitis lethargica, a disease which has sometimes been followed by unsatisfactory changes in conduct. These facts make it clear that delinquency is not simply a problem of mental defect, as some people imagine; it can only be partly dealt with by segregating the feeble-minded. We must, however, recognize that, although we find among delinquents only a small number who actually come under the Mental Deficiency Act, we are likely to find a larger number who are dull and backward. This is, however, such a handicap in life that the unfortunate individual ought sometimes to be regarded as only partly responsible and judged accordingly.

In the next place, it is necessary to think of physical disability or disease. This should always be looked for first in the actual medical examination, because abnormalities of the eyes and teeth, adenoids, paralysis, and so on, are more easily recognized than mental irregularities, and are much easier to treat. The cripple, especially if he has an obvious deformity, is handicapped in the keen struggle for existence; a child with short sight which has not been recognized misses much, and, in addition, bears the heavy burden of a feeling of inferiority. This feeling of inferiority, although not obvious nor recognized by the sufferer, is present in many delinquents; it must be dealt with. It is just as important to recognize the earliest stages of constitutional disorders, such as

tuberculosis. It does not require much gift of imagination to realize that sometimes at the beginning of such a disease the unfortunate sufferer may feel so ill that he is tempted to steal, or to get money in an easier way than by going out to some laborious occupation. Some years ago one such person, instead of being punished for his offence, was placed in a sanatorium for consumptives for four months. Ever since he has remained a satisfactory working member of the community.

Next arises the question: Is there any other group as definite which ought to be considered? The time has undoubtedly come when we ought to recognize as such cases of mental conflict. This is a condition the term for which partly explains itself. One of the simplest examples is afforded by the delinquent who has been forced into the wrong occupation—one for which he is unsuited, particularly if he has special ability or predilection for work of a different kind. The individual with artistic ability who is engaged in monotonous work on a machine comes in this group. All those who have done any psychological work know that as a rule it is of little use to ask such a person whether he likes his work or whether he feels he is fitted for something else. In the majority of cases he recognizes neither his unfitness for the work on which he is engaged nor his capacity for work of a different kind. Ordinary questioning will not elicit the facts, but only observation and thorough investigation on psychological lines. Time is too limited to do more than mention one or two other causes of difficulty in life, such as an extreme father or mother complex, or the unhealthy mental attitude developed in those unfortunate people who have had no moral training at all, or a hyper-Puritanical upbringing, or little or no opportunity for healthy recreation, which is absolutely essential for every growing animal. The necessity of special psychological examination must be emphasized, because many medical practitioners think they have made all the investigation necessary when they have asked a few leading questions. The diagnosis of psychological abnormalities is not easier than that of physical conditions, but far harder and more delicate. What should we think of a doctor who, when called to a patient, makes his diagnosis by asking the unfortunate sufferer whether he has got pneumonia or pleurisy, or whether the pains in his joints are due to rheumatoid arthritis or some more simple condition? Questions of a corresponding kind are of no more use in a psychological examination, for which special training is essential, coupled with some knowledge of mental defect, and still more of mental disorder.

Unfortunately, at the present time the new psychology is under a cloud, for the reason that when it became prominent during the war it was accepted by many who had no knowledge of mental disease and who got no more special training than a course perhaps of six weeks or three months. Then they set to work on unfortunate cases of shell shock, many of whom were unsuited for active treatment, or incapable of ever responding, because they were cases of mental defect or advanced mental disorder, or were so constitutionally inferior that they were never likely to improve much. The psychologists of mushroom growth have already, to some extent, disappeared; but the result of their work still remains to be recorded with what has been done by the smaller number, who are better qualified, and whose work is correspondingly discredited. In dealing with disorders of conduct it is of no use to label a condition as a "psycho-neurosis" or as "hysteria," ignoring the fact that a psycho-neurosis can often not be distinguished from a psychosis, and that an hysterical reaction is not very unnatural when a person feels really ill; it is often exhibited by people who are far from being malingerers. The so-called case of "nerves," so far from having nothing wrong, is suffering from a disorder of the imagination, a condition difficult to investigate and treat. It certainly cannot be dealt with by the stock prescription of recommending a change, and telling the sufferer to forget his troubles. What is the use of ordering a change without investigating first what change is necessary, and explaining how to make it? The psycho-neurotic, like the sick man, is often anxious to make a change in his condition; he wants, more than anyone else, to forget his troubles, but cannot do so until someone shows him how. The fact is that no one is capable

of dealing with such cases unless he knows how to enter into the patient's feelings. An unfortunate little girl, 14 years of age, who had been stealing at school, came from a virtuous but poverty-stricken home, where the father had giving up both drinking and smoking in order that his family might have a better education. Unfortunately, however, he never forgot to remind his family of the great sacrifices he was making. This girl was being pressed at school, in the hopes that she might become a pupil teacher. Having recognized that she had artistic taste I suggested to her how delightful it would be if someone made her a present of a pretty dress, especially if she had a ribbon at the same time for her hair. Her eyes sparkled at once; on discussing the situation she had little doubt that the happiest life for her to look forward to was to become a dressmaker, work for which she was well suited. One advantage would be that if no one ever made her a present of a beautiful dress, as indeed seemed likely, she would at least have leisure some time, when she knew how, to make one for herself.

The question may be asked: If punishment is of limited value, is discipline of no use? The answer is, that discipline is essential, but it must never be repression through fear. Starting in infancy and early childhood with wise suggestion, regulation of habits, and imitation of good examples, discipline must become the result of wisdom founded on the appreciation of reality. The best discipline comes from Nature, which, if we can only see it, teaches us to recognize reality and its force, so great that it cannot be ignored. Discipline comes also from the training given by wise mothers and fathers, coupled with the benefits of rubbing shoulders with brothers and sisters, who constitute a birthright of which the only child is robbed. The discipline of the drill sergeant may lead to perfect conduct, but, so far from leading to perfect character, it often develops no character at all. In order to develop character there must be freedom to develop, after first learning obedience in the early years.

Opportunities for healthy recreation are essential. In this connexion it is important to remember that the Scottish investigation into juvenile delinquency showed that far more offences were committed on Sunday than on any other day, and that the two other most unsatisfactory days were Wednesday and Saturday, which are half-holidays.

In conclusion, it may be thought that I am very revolutionary in my ideas. If so, it will be found by referring to the reports of the important prison conference held in London last August that I have much authority to support me. That conference was the ninth International Prison Conference; the first was held in London in 1872, while the last previous one was held in Washington in 1910. Two facts at this conference were particularly noticed: the first was the tremendous change that had taken place in ideas about crime since the last one was held. The other was the realization that of the fifty-six different countries which sent representatives to the conference some of those countries usually looked upon as backward were found to be, if not actually more, at any rate quite as enlightened as the countries that are generally considered to be in the van of progress. Among the important resolutions passed by the Prison Conference I would direct attention especially to the emphasis laid upon probation. This is one of the most effective means of dealing with delinquency, but in order that it may be effective it must last for a much longer time. If we send a young person to a training college or a university, he usually goes for two or three years, and often for longer. When an offender has already graduated in an unsatisfactory course, how can we hope to train him for something better in such a period as six or twelve months? In many cases the period ought to be not less than five years. Better trained probation officers are required, but one of the chief essentials is to see that before probation begins a thorough examination is made to determine what special arrangements ought to be made conditions of the probation. The conference also attached great importance to the indeterminate sentence, which is the natural consequence of individual treatment, and is the only possible way of dealing with some offenders. The conference emphasized also the importance of special

training for magistrates, going so far as to say that all who wish to be magistrates should be compelled to attend lectures on psychology, sociology, psychiatry, and penology. It drew attention to the importance of scientific investigation of accused and convicted persons, with the object of elucidating the causes of delinquency and discovering the suitable treatment of the individual. It was decided that classification in penal institutions ought to be according to character and ability to be reformed. One of the most important resolutions was that in all cases where parents are incapable of providing for the moral education of their children the court should have the power of boarding out the children in a suitable foster-home.

As a last word I would say that if the important resolutions arrived at by this conference were carried out we should go a long way towards dealing satisfactorily with delinquency.

A SIMPLE MODIFICATION OF THE MIDWIFERY FORCEPS.*

BY

JAMES HAIG FERGUSON, M.D., F.R.C.S.,

F.R.C.P.Ed.,

GYNAECOLOGIST, EDINBURGH ROYAL INFIRMARY; PHYSICIAN, ROYAL MATERNITY HOSPITAL, EDINBURGH.

I HAVE been asked to initiate a discussion on the midwifery forceps, especially in relation to the choice of instrument and its applicability to private practice under modern conditions.

I am not so much concerned with the indications for forceps, though I would like to say that there is a tendency at present, in my opinion, to their too frequent use in these days of hurry and haste, not altogether always to the advantage of either mother or child. I feel sure there is often too much meddling interference nowadays in midwifery, partly for the reason I have already stated—impatience—and partly also with the idea of shortening labours from motives of humanity, which are really short-sighted measures when one comes to analyse them. Suffering can often be mitigated by other and safer means.

Be that as it may, it cannot be denied that the judicious use of forceps is one of the most beneficent and life-saving adjuvants to labour which we possess, in spite of the abuses which have crept in, mainly from their too early application and a failure always to recognize the real indications for their use and their undoubted limitations.

The indications for forceps are generally in a certain proportion of delayed and dangerous labours, but not in all, and the object is to secure the safe delivery of a living child with the avoidance of injury to the mother. These results can in most cases be secured by the judicious and careful use of forceps. A severely lacerated mother, or the delivery of a dead or dying child, cannot surely be claimed as an altogether satisfactory forceps delivery. The practical teaching of the safe use of forceps is one of the most important things teachers have to do. It is a responsibility which weighs very heavily on all who teach obstetrics, and the far-reaching consequences which result from inadequate practical teaching are appalling to contemplate the more one thinks of them.

As I have said already, however, I am not now considering so much the principles involved in the use and application of forceps as some points to which I wish to draw attention in regard to the construction of the instrument, and to indicate what in my opinion constitutes the safest kind of forceps to use (when its use is indicated) with the minimum forceps risk to mother and child.

There is no doubt that the principle of axis traction constitutes one of the most important improvements and advances in the construction of midwifery forceps in recent years (probably the most important). I cannot but think, however, important as the axis-traction principle undoubtedly is, that the purely mechanical aspect of its

*A paper read before the Edinburgh Obstetrical Society, February

application has been carried perhaps a little too far. There are other equally important matters which I believe have been lost sight of in concentrating mainly on the mechanics of attempting to secure, especially at the brim, adequate axis traction with the axis-traction rod forceps in common use.

I feel almost as if I were guilty of boresy if I seem to belittle the importance of the axis-traction rod forceps in a school such as that of Edinburgh, where such magnificent work has been accomplished in that direction by such men as A. R. Simpson and Milne Murray, following on the lines of Tarnier in trying to perfect the axis-traction principle. This great legacy they have handed on to us makes us

FIG. 1.—Blade of forceps showing original long fenestra of Sir J. Y. Simpson, which is retained in Haig Ferguson's modification.

FIG. 2.—Blade of Milne Murray's axis-traction forceps, showing fenestra shortened by half an inch to permit of traction rod being attached as high as possible.

ever their debtors. Their work is abiding for all time. I do not, therefore, for a moment wish to minimize the value and importance of the axis-traction principle. What I desire to criticize is the method by which it is attempted to apply it in the use of the modern type of the axis-traction rod forceps. What I wish to contend for is that in adapting the axis-traction principle with traction rods to the forceps of Sir J. Y. Simpson, while securing a great advance (as we all admit) in the method of traction, we are losing (owing to the construction of the instrument) one of the great advantages of Sir J. Y. Simpson's original instrument, which I regard as the most perfectly constructed forceps in existence, in its measurements and curves, for conserving the interests of the foetus during its passage through the pelvis (Fig. 1).

Sir J. Y. Simpson laid great stress on long fenestrae as being of special importance in preventing undue compression of the foetal head in prolonged forceps cases, and my experience fully bears out his contention. The adaptation of the axis-traction rods to the original Simpson forceps results in the shortening of the fenestrae by half an inch, as the diagrams show; that loss of half an inch, in my opinion, is a very vital loss (Fig. 2).

FIG. 3.—Author's forceps.

In the forceps I will now demonstrate (Fig. 3) I aim at getting axis traction without diminishing the length of the fenestrae, and I claim for this forceps greater simplicity, greater safety, and greater efficiency than the axis-traction forceps with traction rods attached. I showed this forceps to this society fifteen years ago after using it for one year previously. Now, after sixteen years' experience, during which period I have used no other (except occasionally to

demonstrate other varieties in the Maternity Hospital clinics), I can assert that it has given me infinite satisfaction, and compared with other forceps has reduced my foetal mortality in difficult forceps cases by about 10 per cent. This I ascribe mainly to the long fenestrae. There should be no maternal mortality in low and mid forceps cases, and, as Whitridge Williams has shown, the foetal mortality should also be practically nil, except in the rare cases of contracted outlet—often, alas! overlooked.

I can recall only two foetal deaths since using this forceps, excluding cases when other forceps had been used first.

This forceps secures sufficient axis traction in the cavity and at the outlet of the pelvis by using it in the ordinary way with the traction handle adjustment as shown, but in addition one can get real axis traction at the brim by tape traction without shortened fenestrae. The traction tapes are threaded through eyelet holes which are made at the level of the middle of the fenestra in each blade. The attachment of the tapes to the blades is practically, therefore, at the level of the biparietal diameter of the head (opposite the parietal eminences) at a height to which axis-traction rods cannot attain. This high traction on the head through the tapes tends markedly to increase flexion, which is a further advantage. High forceps are so seldom applied nowadays, in comparison with twenty years ago, that I need not elaborate these points. I have not personally for many years had occasion to use this tape traction. When I showed this forceps here fifteen years ago the tape

FIG. 4.—Diagrammatic representation of traction with tapes with Haig Ferguson's forceps. The hand which holds the tapes pulls in the direction of the "practical axis." The head descends in the axis of the "excavation of the pelvis" (aC), a part of the force (A) being annihilated by pressure against the pubes.

traction arrangement at the brim seemed to fascinate all the speakers, to the exclusion of what I regard as the infinitely more important and practical cavity and outlet traction, where the tapes are not used at all.

I may say that the late Professor Fabro of Lyons, whom I regard as one of the most ingenious and sagacious of modern obstetricians, always advocated tape traction, both in high and low forceps cases. He adapted tape traction to the ordinary Levret forceps (as modified by Pajot). Some of Fabre's illustrations show how he utilized tape traction (Fig. 4) ("lacets," as he called them) with the Levret-Pajot forceps (Pajot's manœuvre), and how by combined manipulation with the lacets and with the handles of the forceps he was able successfully to deal with difficult cases. He was also in the habit of using the tapes for securing anterior rotation in occipito-posterior cases as illustrated in the accompanying diagrams (Figs. 5 and 6)—a method which I have also on occasion used. I find that one can generally rotate the head safely in posterior positions by pressing in the required direction with a finger inserted into the lower end of the fenestra. Fabro believed that tape traction allowed the head more freedom of movement, and thus, in virtue of the laws of accommodation, helped it to adapt itself more easily to the diameters of the pelvis. Fabro was in the habit of attaching a dynamometer to the tapes during traction to ensure that too much force was not being used. He regarded 55 lb. traction as the

limit of safety for the child. For practical purposes I believe that biceps traction (that is, with bent elbows) is sufficient for safety.

It will thus be evident that tape traction secures pulling on the head at a higher level than axis-traction rods can

distinctly to emphasize that this, in my opinion, is not its most important role. Its chief value is in the common everyday forceps case with the head well engaged in the pelvis (low and mid cases). Axis traction in such cases can be sufficiently secured by the simply adjustable traction handle, and the retention of the original long fenestrae of Sir J. Y. Simpson adds materially, as I have said before, to the safety of the child.

The measurements from the Smellie lock upwards conform exactly to Sir J. Y. Simpson's measurements (Fig. 7). I have shortened the handles for three reasons: (1) to indicate that they are not meant for traction; (2) to discourage the use of the handles for application, believing as I do that the blades should be applied by the shanks as tending to ensure their more gentle introduction by delicate manipulation; and (3) to allow the traction handle to work free from obstruction by the forceps handles without making the attachment of an inordinate length. The screw is the same as in the ordinary rod axis-traction forceps. Its use can often to a great extent be dispensed with, as the simple device which attaches the traction handle serves for all practical purposes to make the screw unnecessary after the forceps has been adjusted and traction has begun. It will be seen that the construction of this forceps is very simple. There is no complicated mechanism to go wrong—in other words, it may almost be said to be "foolproof," and there is nothing likely to break; it is a light instrument and not clumsy in appearance; and, above and beyond all, it combines the outstanding advantages of Sir J. Y. Simpson's original forceps with the added advantages of axis traction and the minimum amount of compression of the foetal head. With the old Sir J. Y. Simpson forceps when traction was made on the handles the resulting necessary compression of the head was to a certain extent counteracted by the long fenestrae; with the rod axis-traction forceps the axis-traction advantage is to some extent counterbalanced by dangerous pressure on the foetal head owing to the shortened fenestrae. In this forceps, I submit, the advantages of both the old and the new are conserved without detracting from the special features of importance in the construction of either. It is an attempt, and in my experience a successful attempt, to combine what is best in the old forceps with what is best in the traction-rod forceps, the result being an improvement on both.

It must always be remembered that the rod axis-traction forceps was at first constructed and mainly meant for high forceps cases, so as to secure as nearly as possible axis traction at the brim of the pelvis. I have shown that perfect axis traction at the brim is not possible with these rods and is only imperfectly carried out at the expense of shortening the fenestrae.

Incidentally I would here call attention to the classical diagram (Fig. 8) showing the physics of traction, from A. R. Simpson and von Winckel, to illustrate the line of traction with the rod axis-traction forceps. It will be observed that the line AB gives mathematically the true, accurate, and ideal line of proper pull at the brim, but it is an erroneous representation of the pull of the axis-traction rods, which are attached, be it remembered, to the lower end of the shortened fenestrae; and it will be seen that the line AB lies considerably behind the lower end of the fenestrae. The figure therefore gives an incorrect impression of what rod axis traction really does. The line of pull of the rods is considerably further forward than is here represented. The diagram, in fact, correctly portrays what theoretically might be taken as the line of pull with tape traction.

Chassagnay has shown, however, that when traction is exerted at the level of the centre of a movable object

FIG. 5.—Divergent bilateral traction with the two tapes in a right occipito-posterior position to secure anterior rotation. (After Fabre.)

possibly achieve, thus securing more adequate axis traction at the brim. The head becomes more thoroughly flexed by this method of traction (as Davies has pointed out), and, above and beyond all, the fenestrae of the blades have not in any way been interfered with in an attempt to get axis-traction rods attached as high as possible, and even then not high enough to secure completely the object aimed at. It has been adduced that the tapes may break: well, if they do, it is simple to put new ones on. If they break it is probable that too much force has been used, and in this case they make for safety, like an electric fuse. It is a different matter from the breaking of axis-traction

FIG. 6.—Rotation accomplished and occiput lying under the pubes. (After Fabre.)

rods (which has occurred twice in my experience), which leaves the axis-traction rod forceps practically useless. It has also been objected that the tapes may fray the maternal soft parts; this can be prevented by the use of a vaginal retractor or an ordinary Sims speculum to protect the posterior vaginal wall. This is not as a rule necessary, however, as I shall explain later.

I shall now describe the forceps which I use and advocate, and while it is available if need be for tape traction at the brim such as I have been describing, I wish

FIG. 7.—Left blade of Haig Ferguson's forceps showing attachment of removable traction handle.

(*traction au centre de figure*) the line of traction may make an angle of 45 degrees with the axis of the passage without causing friction, and he showed that the advantages of *traction au centre de figure* can be applied to forceps;

FIG. 8.—Diagram showing physics of traction with Simpson's ordinary forceps in the pelvis. (A. R. Simpson and von Winckel.) A B, Line of proper pull. A F, Available pull. A E F D, Parallelogram of forces on A F. A E, Misspent pull. A C, Line of pull with ordinary long forceps (without traction rods).

and this has been confirmed by Fabre, who described tape axis traction at the brim as "*traction au centre de figure*." In other words, if traction is made on the middle of the head, as can be done by tape traction, it is not necessary to pull so far back (towards the coccyx) as with the rod axis-traction forceps, and there is consequently not so much danger of fraying the soft parts with the tapes as one might fear. Indeed, according to Fabre, the line of well directed tape traction need not exceed the making of an angle of 20 degrees with and in front of the umbilico-coccygeal line to get all that one needs. (See diagram showing schematic representation of tape traction—Fig. 4).

FIG. 9.—Mechanical construction of rod axis-traction forceps. (After Milne Murray.) V, Theoretical position for attachment of traction rods. Z, Best practical position for attachment of traction rods (with shortened fenestrae). T, Traction handle.

of the fenestrae, with the ordinary Sir J. Y. Simpson forceps in the pelvis. In Milne Murray's diagram the fenestrae have been shortened and the traction rods attached as high as possible to secure the best available axis traction, which he here mathematically illustrates. Milne Murray admitted that the point V is the theoretical position for the attachment of the traction rods, and he grasped the fact that to make his mechanics anything like perfect the higher the traction rods were attached to the blades the better. He consequently sacrificed part of the length of the fenestrae in an attempt to secure this advantage. But, even so, this axis traction, as will be noted, is not ideal, though for most practical purposes it may be

sufficient. Murray made an attempt to widen the fenestrae, but this did not compensate for the shortening. In addition, wide blades are more difficult to apply.

To put the matter in a nutshell, ideal axis traction at the brim can only be accomplished by traction in the middle of the head, as Fabre has pointed out. Traction rods cannot secure this without seriously shortening the fenestrae. The more the fenestrae are shortened and the higher the rod attachment, the better is the rod traction, but the more dangerous is it for the child, thus constituting a good example of the horns of a dilemma. It follows, therefore, that tape traction at the brim from the level of the centre of the head with full-sized fenestrae is ideally and practically correct, and should produce the best results all round.

I readily admit that the rod axis-traction forceps is equally available (perhaps more so) in the cavity and at the outlet; but again in these situations it is also handicapped by the short fenestrae, which are dangerous to the child with no compensating advantage. Whitridge Williams uses Tarnier's latest model of axis-traction forceps with detachable traction rods and handle bar. In 1910 he writes: "I use this instrument in all cases without the traction rods in low and mid, and with the traction rods in high forceps operations." In 1924 he writes that he uses the traction rods in mid operations as well.

My forceps as it stands is adapted mainly for traction in the cavity and at the outlet, which practically nowadays are the only situations where forceps should be used; but, in addition, this forceps has potential arrangements for almost perfect high axis traction by tape attachment, should an exceptional case demand it.

I do not for a moment contend that tape traction applied to the forceps is entirely a modern idea. Laroyenne in 1875 adapted the laeets of Chassagnay to Levret's forceps, but, so far as I know, this is the first time they have been applied to forceps with an axis-traction handle attachment, thus combining, as I have explained, an alternative method of axis traction (available for all circumstances) in the one instrument.

I confidently submit this forceps for criticism, trial, and approval.

A CASE OF SACRO-COCCYGEAL CHORDOMA.

BY

A. RICHARDSON, M.B., B.S.LOND., F.R.C.S.Eng.,

ASSISTANT SURGEON, GENERAL INFIRMARY, LEEDS;

AND

A. L. TAYLOR, M.B., CH.B.LEEDS,

DEMONSTRATOR IN PATHOLOGY, UNIVERSITY OF LEEDS.

THE fact that up to the present time only 57 cases of chordoma have been published makes it desirable that each isolated case should be recorded. The case here described, the fourth to be diagnosed in Leeds, was encountered recently at the General Infirmary, and presents the typical clinical and pathological features of this rare tumour.

PATHOLOGICAL ASPECTS OF CHORDOMA.

Chordoma, as its name implies, is a growth of peculiar characteristics having its origin in notochordal tissue. Müller (1858) was the first to put forward this view, which, however, received little support at the time. Virchow (1857) and others regarded these tumours as cartilaginous, and small limited outgrowths of this nature arising in the basi-sphenoid continued to be reported under the title of "echordosis physaliphora." It was not until many years later that Müller's views received confirmation from Ribbert (1894), who reviewed the whole subject and advanced the following reasons for his belief in the notochordal origin of the tumours: (1) All spring from the chordal origin of the tumours: (2) In no case has transition from cartilage to tumour tissue been demonstrated. (3) The tumour and the cartilage merely coexist side by side—a persistence of intra-cartilaginous notochordal vestiges. (4) In a chordoma undergoing gelatinous softening the cells do not present the typical physaliphorous appearance of these growths. There is, on the other hand, a close resemblance between

the tissue of a chordoma and that of the notochordal vestiges in the intervertebral discs.

In the following year Ribbert (1895) showed experimentally, by puncturing the intervertebral discs of rabbits, that the escaped nucleus pulposus after a time showed evidence of cellular proliferation, and that its histological structure came to resemble minutely that of chordoma. There could be no doubt, therefore, as to the identity of nature and origin of the two formations.

Chordomas arise with few exceptions at either the anterior or posterior extremity of the notochord. Of the 57 cases so far recorded, including the present one, 25 occurred in the region of the spheno-occipital synchondrosis, 28 in the sacro-coccygeal region, 1 in the occipital region, 1 in the upper and lower jaws, 1 in the cervical and 1 in the lumbar region. In a recent communication Stewart and Morin (1926) have reviewed the whole subject and collected all the cases which have been recorded up to the present.

These tumours do not as a rule give rise to signs and symptoms until adult life is reached. Those occurring in the spheno-occipital region manifest themselves earlier than sacro-coccygeal growths. The average age at which the patients came under observation in the former group was 34.9 years, whilst that of the latter was 50.6 years. Males are affected more than twice as often as females. This is notably the case in tumours of the sacro-coccygeal region, and may lend some slight weight to the theory of trauma as a cause, since males are admittedly more liable to injury than females. The possible importance of trauma as an etiological factor in sacro-coccygeal cases is mentioned by several writers—Bérard, Dunet, and Peyron (1922), Micotti (1922), Andler and Schmincke (1923-24), Stewart and Morin (1926)—who suggest that severe coccygeal trauma may liberate chordal tissue from its normal osseous control and even stimulate its proliferation. On the other hand, in many cases there is no history of antecedent trauma.

Chordoma is a malignant tumour; generally of slow growth, it infiltrates and destroys hard and soft tissues alike, and is very liable to recur after removal, but rarely gives rise to metastases. In some cases, however, growth may be more rapid, and metastatic deposits have been described in lymph glands (Peters, 1919), liver (Pototschnig, 1919), and other tissues (Stewart, 1922). The ultimate prognosis in chordoma is bad; the average duration of life after the first appearance of symptoms in spheno-occipital cases is 2.8 years. In sacro-coccygeal cases the tumour is not so rapidly fatal; the average duration is 6.4 years. Stewart (1922) published a case which developed metastases five or six years after the first operation, the patient eventually dying eleven years after the primary tumour was first discovered. The more serious nature of the spheno-occipital variety is undoubtedly due to its position and to the gravity of the operation for its removal.

CLINICAL ASPECTS OF CHORDOMA.

1. *Chordoma of the Spheno-occipital Region.*—The clinical signs of tumours in this region are usually those of a slowly growing tumour involving the base of the skull and adjacent nerve structures—headache, vomiting, dizziness, and progressive failure of vision being the early symptoms. Paralysis of various kinds depend on the size and situation of the tumour. The enlargement is usually directed upwards into the cranial cavity, but some tumours have extended downwards into the naso-pharynx or into the sphenoidal sinus or orbit.

2. *Chordoma of Sacro-coccygeal Region.*—These tumours frequently become painful at a fairly early stage. The pain is localized in the region of the sacrum and coccyx or may be felt in the buttocks and legs. Lumbago and sciatica may occur and interference with micturition and defaecation may arise in the later stages. The symptoms depend mainly on the direction in which the tumour enlarges. Backward extension eventually causes a tumour in the region of the lower end of the sacrum and coccyx. The tumour is situated in the middle line, is of slow growth, and firm and elastic to the touch. Tenderness is not as a rule a pronounced symptom. The overlying skin retains its normal appearance and is usually freely movable

over the tumour, which is firmly fixed to the deep tissues. If the enlargement is in a forward direction, towards the hollow of the sacrum and the rectum the main symptoms may be referred to the latter organ. Obstruction to the passage of faeces and even ulceration may occur; or, from interference with the venous return, haemorrhoids may develop. This condition has arisen in several cases as an early sign. In the present case the patient underwent an operation for haemorrhoids four years before the tumour was discovered, but this was probably merely coincidence, for at the time of operation for removal of the tumour there was no forward extension sufficient to produce obstruction to the blood return from the rectum.

REPORT OF CASE.

The patient, a male aged 43, first noticed a small swelling at the lower part of the sacrum in November, 1924. It was slightly painful and tender, and slowly increased in size. The pain became gradually worse, and five months afterwards was present in the left buttock and thigh. It was thought to be sciatica, but did not improve under treatment. On admission to the General Infirmary on November 7th, 1925, he presented a slightly lobulated rounded tumour the size of half a Tangerine orange, situated in the middle line at the level of the junction of the sacrum and coccyx. The tumour was rather tender on pressure and the skin, though somewhat adherent, was normal in appearance. The growth was firmly fixed to the deep tissues and no movement whatever could be detected between it and the underlying bone. It was of firm elastic consistency and gave no signs of the presence of fluid. On rectal examination a vague irregular fullness could be felt in the hollow of the sacrum. The rectal wall was not adherent to the tumour nor was the latter projecting into the lumen of the gut. The fullness was confined to the middle line and the upper limit could be felt by the tip of the examining finger.

Operation, November 10th, 1925.

Under general anaesthesia a vertical incision was made over the tumour. The skin, which was more adherent than had appeared clinically, was dissected back and the edge of the tumour defined. It was found to be firmly attached by a wide base to the lowest piece of the sacrum. On attempting to cut it free from the bone it burst and a large quantity of jelly-like material escaped. It was then found that the bone itself was eroded and infiltrated with growth which passed high up into the sacral body. As much of the tumour as possible was removed and the sacrum itself curetted, a large quantity of jelly-like tissue and several pieces of eroded bone being removed. Haemorrhage was free. The wound was packed and partially closed. There was a considerable amount of bleeding after the operation which necessitated repacking. The wound eventually healed by granulation, and the patient was discharged after several weeks in hospital.

Morbidity Anatomy and Histology.

The portion of tumour removed, some 2½ inches in diameter, is elastic to the touch, well encapsuled on its superficial aspect, and shows distinct lobulation. The deep surface is ragged and irregular where it has been detached from the underlying bone. On section the growth has a characteristic alveolar appearance, the lobules being separated from each other by fine fibrous trabeculae. The nodules of growth consist of translucent whitish gelatinous tissue and often show central cavitation, as a result of the extreme mucoid change which is present. Numerous small areas of haemorrhage are scattered throughout the tumour.

Histologically the appearances correspond precisely with those of previously reported cases of chordoma. Solid masses of epithelial cells are situated for the most part in contact with the connective tissue septa. Their nuclei are small and rounded or irregular in shape, with ill defined chromatin network. The cytoplasm is abundant and finely granular, but of very indefinite outline, so that one cell is not easily distinguished from its neighbours. This solid appearance is characteristic of the youngest cells; most of them, however, show the marked cytoplasmic vacuolation typical of chordoma, with formation of mucinous material which escapes from the cell to form large homogeneously stained areas in the centre of the tumour lobules. Throughout these areas are scattered blood cells and isolated epithelial cells. Histological evidence of malignancy is but scanty; no mitoses are observed, and cells of the more embryonic type described constitute only a small portion of the tumour. On the other hand, the large amount of mucin present is, as Stewart and Morin (1926) have pointed out, an indication of its comparatively benign nature.

COMMENTARY.

Although as much of the tumour as possible was removed by dissection and curetting, the extensive bony involvement makes it practically certain that some of the tumour tissue remains behind. Recurrence, therefore, will almost certainly take place, but as the chordoma histologically appeared to be of very slow growth it may be some considerable time before operative intervention is again necessary.

The pain in the left buttock and thigh, which disappeared immediately after the operation, returned within two months. The operation wound is healed, and there is

no evidence of recurrence *in situ*. Rectal examination reveals no sign of anterior extension of the growth towards the bowel. The patient is now undergoing x-ray treatment, so far with no relief of his pain.

THE PROPHYLACTIC VALUE OF SCARLET FEVER ANTITOXIN.

BY

E. H. R. HARRIES, DOROTHY HERVEY,
M.D.LOND., M.B.BIRM.,

AND

VERA FELLOWES, M.B.BIRM.
(From the Birmingham City Hospitals.)

AN opportunity recently occurred of testing the degree and duration of passive immunity conferred by prophylactic doses of scarlet fever antitoxin. As the procedure adopted involved several of the new methods in scarlet fever, we think that some account of our observations will be of interest.

In a diphtheria ward a girl, aged 12, convalescent from the disease, and therefore up and about, developed scarlet fever. The diagnosis of this case was confirmed by a very marked Schultz-Charlton reaction, produced by the intradermal injection into the rash of 0.2 c.cm. of horse scarlet fever antitoxin, and also by a positive Dick test. As the child had received diphtheria antitoxin many days before, she was first desensitized with 1 c.cm. of horse serum in the ordinary way, and then received 25 c.cm. of an unconcentrated scarlet fever antitoxin intramuscularly. The temperature, which overnight had risen to 103.8°, dropped by crisis to normal by the morning. The rash, which had become very intense before serum was given, completely disappeared in less than thirty-six hours; the temperature remained normal, and the child to all intents and purposes was quite well, and has remained so. This child had no previous history of scarlet fever. On the same morning another girl, aged 10, vomited and complained of slight sore throat. The tonsils were observed to be congested, and she presented an extremely faint pink flush over the trunk; her temperature was found to be 101°. Although this child was stated to have had scarlet fever "at home" a year previously, the Dick test was positive. The flush on the trunk was so fleeting that no Schultz-Charlton test was feasible. We have no doubt that this patient had an abortive attack of scarlet fever, but she was nevertheless dealt with in the same way as will be described in the case of other contacts in the ward.

On the occurrence of these two cases a search was made for the source of infection. A girl, aged 12, who had been admitted six days previously with severe faucial diphtheria, was found to be desquamating on the hands. Careful inquiry elicited the fact that nearly three weeks prior to admission to hospital she had complained of a sore throat, and that a rash had been noted on her back and legs. The Dick test in this case was negative to a dilution of toxin which we are satisfied after some hundreds of trials in various dilutions constitutes in 1 in 1,000 dilution a reasonable skin test dose. This toxin (X48) was supplied to us by Dr. R. A. O'Brien, and is the toxin used with corresponding controls of heated toxin throughout the Dick tests described in this paper. This negative response to a skin test dose of Dick toxin was consistent with our previous experience of the Dick test performed on cases of scarlet fever in the third week or later. We have no doubt that this girl, herself immune to a skin test dose as a result of a recent attack of scarlet fever, was the source of infection.

Although we and others of our colleagues in the Birmingham City Hospitals are satisfied, as the result of a long series of trials, that 0.2 c.cm. of 1 in 1,000 dilution of toxin X48 constitutes a skin test dose, we have in this series of cases, and as part of a larger piece of work, used not only 1 in 1,000 dilution, but also 1 in 500. The use of these two dilutions, one twice as strong as a normal skin test dose, gives us a measure of the immunity possessed by the patient in excess of that denoted by a negative skin test dose. All the contacts, therefore, were tested with both these dilutions, as were also the two infected cases and the infecting case. The latter, as already stated, gave a negative response to 1 in 1,000, but was positive to 1 in 500.

Of the 16 contacts, 14, including the abortive case of scarlet fever already mentioned, gave positive readings to both dilutions; the two exceptions, who had well authenticated (hospital treated) previous attacks of scarlet fever, were completely negative to both dilutions, showing that as a result of a previous attack they possessed an immunity to scarlet fever toxin far in excess of that denoted by the skin test dose. It was determined to produce passive immunity in these 14 cases. Two scarlet fever antitoxins from different sources were employed for this purpose. Scarlet fever antitoxin "C" was a concentrated antitoxin, of which we had a small supply for testing: It was stated that each cubic centimetre would neutralize "at least 50,000 skin test doses of scarlet fever toxin," and that 2.5 c.cm. constituted a dose which would produce passive immunity. Scarlet fever antitoxin "U" was an unconcentrated serum, part of an experimental batch. We had previously ascertained that 0.2 c.cm. of 1 in 1,000 dilution of this batch of serum would produce local blanching when injected intradermally into a recent scarlet fever rash. We also know that 10 c.cm. of this unconcentrated serum would convert a Dick-positive reactor into a negative reactor in twenty-four hours. We therefore in 4 cases employed 2.5 c.cm. of the concentrated serum, and in 10 cases 10 c.cm. of the unconcentrated serum. In every instance the intramuscular route was employed; thirty-six hours after the serum had been administered the patients were again tested with the same dilutions of the same toxin, and the results of these tests, together with subsequent tests at intervals, are set out in the chart.

One of the disadvantages of the use of unconcentrated scarlet fever antitoxin serums when used in therapeutic doses has already been noted by one of us—namely, the occurrence of serum rashes which may be quite severe. Hence a very careful record was kept of the occurrence and severity of any serum phenomena after the use of prophylactic doses of concentrated and unconcentrated serums respectively. It will be seen from the table that none of the 4 cases given concentrated serum in doses of 2.5 c.cm. developed serum rashes; whereas 6 of the 10 who had received 10 c.cm. of the unconcentrated serum developed trifling rashes, in most cases on the arms and legs only. One rash was scarlatiniform in type, and confined to the back.

The following chart sets out the results of all the observations which were made.

A study of the chart shows that as a result of administration of 2.5 c.cm. of a concentrated antitoxin or 10 c.cm. of an unconcentrated antitoxin, immunity was produced in thirty-six hours in all cases to a skin test dose of toxin; and in 9 of the total to a dilution of toxin twice as strong. In a week's time all the 4 cases who had received the concentrated serum were still negative to a skin test dose, whilst 3 gave minimal reactions to the 1 in 500 dilutions; 4 of the 10 cases who had received unconcentrated serum gave minimal positive results to 1 in 1,000 dilutions at the end of a week. In all these cases the 1 in 500 dilution was, of course, also positive. Two children remained negative to both dilutions. A week later still re-tests were performed with the same toxin in the same dilutions. One child who had received concentrated serum still remained negative to both dilutions, whilst 3 gave positive reactions—two of them minimal—to 1 in 500. Four of those immunized with unconcentrated antitoxin still remained negative to the 1 in 1,000 dilution (two of these to both dilutions). Five children reacted positively to both dilutions, and the remaining child had been discharged from

○ NEGATIVE ● POSITIVE ◐ POSITIVE OF SMALL AREA OR FAINT POSITIVE

Note.—Only 6 cases showed serum phenomena. These were as follows: Cases 5, 9, 10, and 15 had urticaria on arms and legs; Case 12 on arms only. Case 13 had a scarlatiniform rash confined to the back. Cases 4, 8, and 15 were the only ones with a previous history of scarlet fever.

hospital before this second re-test could be carried out in her case.

A fourth re-test in twenty-one days of 6 children who had remained negative to a dilution of 1 in 1,000 at the third re-test was carried out. All 6 of these children were still negative to 1 in 1,000; 3 of these 6 had received concentrated antitoxin, and one of these 3 still remained negative to 1 in 500 dilution. The remaining 5 gave small reactions to 1 in 500 dilution.

It may be concluded, therefore, that 2.5 c.cm. of a good concentrated scarlet fever antitoxin will protect a child susceptible to scarlet fever (as assessed by a skin test dose of Dick toxin) for at least a fortnight, and that 10 c.cm. of an unconcentrated serum of known high blanching titre will confer similar protection, although with less certainty. Concentrated serum in a dose of 2.5 c.cm. did not produce a serum rash in any of the four cases investigated. There is the additional advantage that such a small bulk of serum is in itself in the neighbourhood of a desensitizing dose of horse serum; hence in the case of a child who has previously received diphtheria antitoxin the process of desensitization may be safely omitted if only such a small bulk of scarlet fever antitoxin is requisite.

It should be added that all the cases related above, including the infecting and the infected cases, were removed, as soon as the results of the first Dick test after serum were read, to an ordinary scarlet fever-diphtheria ward. They were consequently exposed to the infection of scarlet fever throughout the period recorded. No instance of infection occurred amongst any of the transferred children. We have no doubt that the practitioner in charge of children's institutions now has available in the Dick test and in scarlet fever antitoxin the means of prompt control of an outbreak of scarlet fever. Scarlet fever antitoxin may be used for either of three purposes: (1) intradermally, preferably diluted to 1 in 10 with normal saline, for the diagnostic Schultz-Charlton reaction; (2) intramuscularly or intravenously, in therapeutic doses, for the treatment of the disease; (3) intramuscularly, for the production of temporary passive immunity.

PHENOLAINE IN OPHTHALMOLOGY.

Mr first introduction to phenolaine was through Mr. Nesfield's *Ophthalmic Surgery*. After a fairly extensive use of it during a period of two years I share his enthusiasm and regard the drug in ophthalmology as one of the most important in our armamentarium.

The reason for this communication is that I have inquired from several ophthalmologists if they had had any experience of it, and have received negative replies, and my hope that it will lead to a trial in those cases in which it is especially recommended—nebulae and leucoma of the cornea.

My first experience with phenolaine was in a case which I will briefly describe, and in which the result was miraculous, using the word Mr. Nesfield quotes in relation to the drug.

A boy, aged 6 years, was sent to me by Mr. Claude Avarne in October, 1925. The boy had had a most severe attack of whooping-cough in January of that year. The mother then noticed that the right eye began to turn in. When I saw him he had a decided right convergent strabismus, could not fix with that eye, and had no perception of hand movements. Ophthalmoscopic examination revealed an old mass of vitreous opacity, barring absolutely any view of the fundus. This mass was evidently the result of a haemorrhage into the vitreous due to the whooping-cough.

I had just been introduced to phenolaine, so I began, according to directions, subconjunctival injections. I gave one a month. After the fourth injection the vitreous became absolutely clear, and has remained so. I followed up with one other injection.

A tucking operation then followed to reduce the squint. Owing to the subconjunctival injections there was a most alarming chemosis during the process of healing, so much so that I had to snip the conjunctiva to promote drainage. The result of the tucking operation, in spite of all, is perfect. Owing to the length of time the eye had squinted it is amblyopic + 1.00 Sph. V.=6/36. From a blind eye this is surely a triumph for the injections.

I have since used phenolaine in many cases of old nebulae, and have never met with disappointment. I always urge it with confidence. Cases that could only read Jaeger 6 have been brought up to 1 or 2. I have not used it in patients over 30. The strength is that Mr. Nesfield recommends—2 minims to an ounce of sterilized tap water. I use water which has passed through a Pasteur-Chamberland filter, but phenolaine possesses very high antiseptic and anaesthetic properties. Tap water has a great deal to do with its action, according to Mr. Nesfield.

ARNOLD FERGUSON, F.R.C.S.Ed.,
Ophthalmic and Aural Surgeon,
Jersey General Hospital.

INTRAUTERINE AMPUTATION OF LEFT LEG.

On Monday forenoon, September 28th, 1925, I was called to see a woman, aged 33, who was due to have her eighth confinement in the beginning of November. She thought she was in labour, as she had been having pains since September 26th, and was alarmed at the delay.

The uterus was up to the level of the umbilicus and indicated a transverse presentation; the os uteri was well dilated with the right shoulder presenting. Under chloroform the shoulder was pushed up, and in manipulating for a foot my finger came against a very sharp end of bone, and I also felt a small foot and leg lying free inside the uterus. I secured the normal foot and easily delivered a live boy, my only fear being that the uterus might get damaged by the pointed stump of the femur. I then removed the detached foot and leg.

On examining the child I found that the left leg was amputated about the middle of the thigh, the stump being completely healed except that the femur projected about a quarter of an inch—a condition similar to that found during the war after circular amputations that had been allowed to granulate. The amputated part was macerated and much smaller than the other limb—about 5 months as compared to 7½ months. There was nothing abnormal about the placenta, which came away easily within ten minutes of the birth. The cord was somewhat longer than usual and very thin. The woman made an uneventful recovery and was up on the tenth day.

Up to the seventh child there was no trouble with any of her babies. Between the sixth and seventh, which was a breech, she had an abortion at the third month. All the children were born alive, but small. She is rickety and has a justo-minor pelvis.

Among the points of interest in this somewhat rare case are that the child was born alive, it cried feebly for ten minutes, showing that the constricting force was not likely to have been the umbilical cord, as otherwise a dead child would have been expected; if the force was sufficient to cause amputation it would have been sufficient to stop the flow of blood in the vessels of the cord. It is conceivable, however, that by slow pressure, the tissues being soft, especially the bone, amputation might take place without the death of the child and the condition of the cord might support this view. The stump being healed is sure proof that amputation took place some month or two previously and this conclusion is strengthened by the size of the amputated part.

The condition differs from the more common types of ectromelia where, owing to pressure as a rule of an amniotic band, there is non-growth of a limb or part of a limb; in this case the limb was developed, and what caused the amputation is difficult to say. None of the textbooks at my disposal describe such a condition. Unfortunately I was unable to secure the body or even photographs.

TWO NEO-NATAL DEATHS.

THE two following cases seem of sufficient interest to be placed on record. The first occurred in the practice of Drs. Chapple and Slack at Stairfoot, Barnsley.

A male infant was born at 4.15 a.m. on December 21st, 1925; a certified midwife was in attendance. The mother had had six stillbirths, and one child who died in infancy; only one girl survived. The midwife reported that the child appeared to be fully developed, cried lustily, but soon appeared to be in pain. She called in a doctor (under the Midwives Act, 1918). One of us (A. B. S.) attended, and found that the clothing of the child was saturated with blood; the child died an hour afterwards.

At a *post-mortem* examination, when both of us were present, the umbilical cord appeared to be properly tied in two places, and the ligatures were firmly *in situ*. There was a small crack or ulcer, hardly noticeable, where the umbilical cord joined the skin of the abdomen, and it seemed that oozing had taken place from this. On opening the abdomen much free haemorrhage was seen in the peritoneum below the spleen, where there was a large clot. Apart from a large thymus the remainder of the body appeared fairly normal.

In this case, without a *post-mortem* examination it would have been difficult to combat the suggestion that the death was due to haemorrhage from faulty ligation of the cord. The internal haemorrhage and the family history, combined with the external haemorrhage, were very suggestive of haemophilia. This suggestion was adopted by the coroner at the inquest.

The second case was brought to the notice of one of us (T. E. F.) by the coroner's officer, who called on January 16th, 1926, with the following note:

"At 4.30 a.m. to-day, Mrs. E. H. gave birth to a male child, a certified midwife being in attendance. The midwife left at 6 a.m. At 12.15 p.m., when she returned again, she found the child dead in bed beside the mother. Dr. P. was called in and pronounced life extinct."

The history of the case suggested overlying, but the midwife stated that the child was born with the cord around the neck. A *post-mortem* examination was conducted on the following day by Dr. P., when T. E. F. was in attendance. The child appeared fully developed and well nourished, but the head was intensely congested. On opening the thorax, however, the small intestines and spleen were found in the left side of the chest above the diaphragm, compressing the heart and lungs towards the right. The lungs appeared to be only half the normal size. A large foramen or gap was present in the left side of the diaphragm immediately adjoining the twelfth rib. It readily admitted one finger, and the intestines and spleen could be pulled back into the abdominal cavity.

These cases show the desirability of holding a *post-mortem* examination in all cases of infant deaths where the cause is not certain. Incidentally also the cases point to the difficulty in reducing the infantile mortality of the first week of life, when congenital malformations and abnormalities produce their toll.

Reports of Societies.

MALARIAL TREATMENT OF GENERAL PARALYSIS.

At a meeting of the Section of Medicine of the Royal Academy of Medicine in Ireland held on April 23rd, the President, Dr. F. C. PURSER, in the chair, Dr. GEOFFREY BEWLEY read notes on two cases of general paralysis treated with malaria parasites. Dr. Bewley said that both patients had a fully positive Wassermann reaction of the cerebro-spinal fluid, a cell count of about 50 per c.mm., and a strongly positive colloidal gold curve. In each case the rigors occurred every evening and were controlled by quinine after ten had occurred. In the first case the mental change was dramatic, the patient becoming perfectly normal in a fortnight and being discharged from the asylum six weeks after treatment; the Wassermann reaction had then become negative, the cell count almost normal, and the colloidal gold curve that of a very weak parietic. Four weeks after being discharged this patient had an acute melancholic attack and was certified again. In the second case three weeks after treatment the Wassermann reaction had dropped to *plus 1* for 0.1 c.cm. and the cell count practically to normal; the colloidal gold curve remained unchanged. The mental change, however, had shown a slight but steadily progressive improvement.

THE PRESIDENT said that this was the first communication on this subject which had been brought before the Academy, although work on these lines had been going on in Dublin for some time. The clinical results in Dr. Bewley's cases seemed to him to be quite as good as in any of those he had seen reported. The pathological results in the first case were very good, and made him think that there was more in this treatment, in the way of permanence, than was thought by many who tried it. He had seen the first patient with Dr. Bewley, to certify him, and there was certainly no doubt about the condition being general paralysis of the insane.

Dr. H. T. BEWLEY said that he had seen these patients frequently, and the first was a typical case of general paralysis as regarded the mental state. The recovery was the most dramatic in mental medicine that he had ever seen, as it occurred with such suddenness. The second illness of the patient was also very sudden, and did not look at all like general paralysis. The patient became melancholy and threatened suicide; he became dull and stupid, and it was very difficult to get him to take food. Although there was no stricture in the urethra, he did not seem to care to pass water, but just allowed his bladder to become distended. In the second case there was a gradual but very marked improvement. Nothing dramatic had occurred, but the patient was a great deal better, and seemed to be improving steadily day by day, since the malarial treatment. Dr. Bewley referred to the small degree of general illness of the patients. On the evening of treatment the temperature might be high, but next morning the patient was perfectly well, and did not suffer from any depression or weakness such as was common when a patient's temperature was high. It was a very great disappointment that the first patient had relapsed, after such a brilliant recovery. He hoped that the second patient would go on improving, and ultimately regain mental vigour completely, or at any rate to a very large extent.

Dr. H. R. C. RUTHERFORD referred to a report of Dr. Graham of the Mental Hospital, Belfast, on malarial treatment for general paralysis. In 1923 Dr. Graham had treated seventy patients, and was able to discharge thirty, of whom twenty-one were absolutely well, and remained well for long periods, varying from a year to a year and a half. Nine went away at their own request, against his advice, and of these two returned for further treatment. Twenty-eight did not improve, and one case failed to develop malaria. Dr. Graham had no doubt that this was a very valuable treatment.

Dr. JOHN DUNNE of the Richmond Hospital was also enthusiastic about the treatment. The pathological

results in Dr. Bewley's patients had been better than in Dr. Graham's, in that although Dr. Graham's patients regained mental health they did not improve much physically, and their Wassermann reaction was often positive, even when cured.

Dr. E. S. HONGAN referred to the close correspondence between the Wassermann and the colloidal gold tests, especially if the Wassermann test was performed in double dilutions. He thought it would be interesting to follow up the further clinical symptoms in these cases, and see whether the improvement would continue parallel between the colloidal gold and Wassermann reactions on the one hand and the symptoms on the other.

Dr. G. E. NESBITT referred to a case of his own at present under treatment. Dr. A. R. PANSOXS asked if there was any danger associated with malarial treatment, and said that it was very difficult to understand what had caused the reaction and what was going on in the first patient's brain.

Dr. BEWLEY, replying, said that he had never experienced any difficulty in finding malaria parasites; in every film he had found parasites in every stage. The serological results were not nearly so important as the mental results. There was some danger in the treatment; it was dangerous to allow rigors to continue for a long time, and the onset of jaundice or hyperpyrexia was dangerous. He thought, however, that it was quite justifiable to subject patients to a very considerable risk if by doing so there was a possibility of curing them of a disease which was otherwise incurable.

Scleroderma.

Dr. KATHLEEN LYNN showed a case of scleroderma in an infant aged 7 months. She said that scleroderma generally attacked infants of only a few days of age; they usually died from it in a short time. This infant had been perfectly normal until it was 2 months of age, but the symptoms then became well marked. She thought that some improvement was occurring.

Dr. M. DRUMMOND said that this case was almost unique in some respects, especially as the child had lived so long. Generalized scleroderma was very unusual. He personally had seen only two patients; one had died at 2 months of age and the other at 5 months of age. He did not think that much could be done for the child. In some generalized cases in older children ultra-violet rays had been given with success, but he felt that in such a young child this treatment might be a risk.

The PRESIDENT said that it was three days since he had first seen the infant; it was certainly no worse, but he did not think it had improved. He asked if there was anything which suggested a syphilitic history.

Dr. LYNN, replying, said that there was apparently no specific history in the family. The father had recovered from tuberculosis, and was now in fairly good health. There were nine children, one an idiot; three were still alive, and six dead. The mother was a delicate-looking woman. In cases of scleroderma the temperature was raised, but this infant's temperature was always subnormal. There had been no gain in weight, but she thought the child had improved a little, though some days it was better and others worse.

Clinical Cases.

Dr. M. DRUMMOND showed a case of tubercle of the skin simulating leprosy. The resemblance to leprosy was very striking, there being complete absence of ulceration. The ends of the fingers were red and swollen, and the terminal phalanges showed a rarefying osteitis. A portion of skin was removed on two occasions for examination, and the structure was found to be tuberculous. Dr. W. D. O'KELLY said that in specimens taken from this patient characteristic tubercle bacilli had been found, but no leprosy bacilli. He had, however, inoculated a guinea-pig, which had shown no signs of tuberculosis, and no cultures of tubercle bacilli were obtained. The resemblance to leprosy in this case was very great, but he personally thought it was a case of tuberculosis, although he had failed to find tubercle bacilli.

Dr. W. G. HARVEY showed a case of alkaptonuria. Marked pigmentation was to be seen in the sclerotic and slight pigmentation in the cartilages of the ears. The patient developed some nasal obstruction, and nasal cartilage had to be removed; this was found to be pigmented in spots. Sir JOHN MOORE said that this patient was an old soldier who had served in India; thirty years ago he had had haematemesis, apparently caused by an overcharged liver, due to the mitral lesion which was still present.

Dr. L. ABRAHAMSON showed a case of syphilitic disease of bone simulating rheumatoid arthritis. There was, on admission to hospital, marked swelling of both ankles extending to the upper malleoli and over the posterior third of the foot. Tenderness was present, and movement was markedly limited and painful on both sides. The Wassermann reaction was strongly positive. An x-ray examination showed pronounced periosteitis, involving the lower end of both tibiae, with deposition of bone, which had been laid down in a peculiar frilly form. Anti-syphilitic treatment was followed by marked improvement in the symptoms and the swelling, though bony changes persisted. In three weeks the patient was able to walk without discomfort.

Dr. G. E. NESBITT showed electro-cardiograms from two cases of a rare type. One was paroxysmal tachycardia, apparently ventricular tachycardia, and the other was left bundle branch block. Dr. Nesbitt believed that ventricular tachycardia was a very rare condition. Dr. L. ABRAHAMSON said that ventricular tachycardia was an exceedingly rare condition, and, apart from this, he thought that some of the cases which were published as ventricular tachycardia were really not ventricular, but ordinary tachycardia. He was quite convinced from the electro-cardiograms shown by Dr. Nesbitt that his case was one of ventricular tachycardia. He asked him if he thought that the fine notches shown at the top of the waves represented the ventricular beat. He personally thought they did, and if so it was especially rare. The long pauses in the tracing showed evidence of sino-auricular block, which also was very rare. He agreed that Dr. Nesbitt's second case was one of left bundle branch block, but the diagnostic criteria of this condition were not as yet firmly established by necropsy findings.

RESULTS OF PLASTIC SURGERY.

At a meeting of the Bristol Medico-Chirurgical Society held at the University on March 10th, with the President, Mr. T. CANWARDINE, in the chair, Mr. H. D. GILLIES read a paper on the functional and aesthetic results of plastic surgery. Starting with the deformities resulting from gunshot wounds of the face, Mr. Gillies said that the broad principles underlying their repair were: (1) to conserve every scrap of undamaged tissue; with this end in view, close the wound as soon as possible, sewing skin to skin or mucous membrane; (2) to replace all normal tissue in its proper place; (3) to bring fresh healthy tissue to close the gaps, both in skeleton and soft parts. He then spoke of the evolution of the tube graft and its application in the repair of shell wounds, giving numerous illustrations from photographs of the various stages, and the results. The method of measuring and fitting grafts by the help of plaster casts and stencils was described. The use of Thiersch and Wolfe grafts was shown, and the occasional cosmetic disappointments with the latter mentioned. When repairing the face, and especially the nose, the lecturer emphasized the necessity of providing a mucous membrane, or at least skin, to replace the destroyed mucous lining of cavities. In this connexion he described the "stent" inlay graft, and illustrated its application in the nose, in the mouth, and for ectropion. Loss of part of the lower jaw was repaired by means of bone grafts and dental prostheses; cartilage grafts were used to repair nose and forehead, and dental prostheses for loss of the upper jaw. The results of treatment of scarring after severe burns were illustrated. Mr. Gillies then turned to the application of these principles to the deformities of civil life resulting from burns, industrial or motor accidents, and

extensive operations. The method of treating facial naevi and hairy moles was shown, and the important social and psychic bearing of these deformities mentioned. The general principles of plastic surgery evolved for the treatment of the face were not confined to this region. Destruction of tissue in the limbs might be amenable to treatment along these lines when other methods offered little prospect of success. Means for improving the functional results after cleft palate operations were shown, and the repair of damage to the pudenda in both male and female described. Finally, purely cosmetic manoeuvres, such as the rectification of a "Semitic" nose, were indicated. The lecturer concluded by saying that the secret of success was a correct diagnosis. One must ascertain exactly what was missing and had to be restored. Care on the part of the surgeon, and patience, both from him and from his patient, were the other requisites. A very complete series of photographs illustrated each of the various processes, and demonstrated the truly remarkable results that the lecturer had been able to achieve.

PREGNANCY IN A DOUBLE UTERUS.

At a meeting of the North of England Obstetrical and Gynaecological Society in Manchester on April 16th, the President, Mr. W. GORER (Leeds), in the chair, Dr. J. W. BRIDE (Manchester) described a case of obstructed labour due to uterus didelphys, which was particularly interesting in that two separate and well formed vaginas were present, and that in the first pregnancy the unimpregnated horn effectually obstructed delivery.

A primipara, aged 25, was admitted to St. Mary's Hospitals, Manchester, on January 26th, 1922, as a case of either pelvic tumour obstructing delivery or a full-term ectopic pregnancy. There was a history of pains for two days, and a show. On abdominal examination the uterus was found to be tonically contracted, and the lie of the foetus was oblique, the back being to the mother's left and front and the head in the right iliac fossa. No foetal heart sounds were heard. On vaginal examination two separate, well formed, and dilated vaginas and cervixes were found; the left was fully dilated and the membranes were ruptured. The pouch of Douglas was filled with a soft mass, which could not be pushed up by moderate pressure. A diagnosis of pregnancy in the left horn of a double uterus with the right horn obstructing delivery was made, and it was decided to perform Caesarean section at once. The left pregnant horn of a uterus didelphys was exposed, and the wall was so thin that the foetus was readily seen through it. A dead, well developed, but slightly macerated foetus was extracted, and the uterine incision sutured with catgut. The right horn lay retroverted in the pouch of Douglas, and quite obstructed delivery. The true conjugate of the pelvis was found to be 3½ inches. On account of the poor condition of the patient, nothing more was undertaken at the time. A decidual cast was passed on February 1st. The patient made a good recovery, being told on her discharge, on February 14th, to report at once if she became pregnant again.

Dr. Bride next saw her at the seventh month of pregnancy in 1925, and she was admitted to hospital on June 6th, with slight labour pains. The foetus lay transversely, the head in the left iliac fossa. No vaginal examination was made, but it was thought that the right horn was pregnant on this occasion, and bearing in mind the extreme thinness of the wall of the pregnant horn in the previous labour he decided to perform Caesarean section at once. A pregnancy of the right horn was found; again the wall of the uterus was so thin that the foetus was visible through it, and it was contracting. A living male child, 6½ lb. in weight, was delivered. The patient did not wish to be sterilized. The left horn was lifted out of the pouch of Douglas, the scar of the old Caesarean section was found well healed, and there were no adhesions. The mother was discharged on June 29th, and the child was alive and well.

Dr. Bride summed up the main points in the case. In each labour a different horn was pregnant, and the non-pregnant horn obstructed labour quite apart from pelvic contraction. He thought that the extremely thin wall of the horn would have given way in prolonged labour. A decidual cast was passed in the first pregnancy. The interesting uterine malformation would have rendered likely a mistaken diagnosis of tumour or ectopic pregnancy if the vaginal malformation had been absent or not recognized.

The President remembered a similar case in which spontaneous delivery of a breech had occurred with uncertainty as to the degree of dilatation of the cervix, owing to examination of the wrong half of the vagina.

Professor H. BRIGGS (Liverpool) emphasized the fact that the non-pregnant horn was never drawn up out of the pelvis, and that obstruction to delivery was almost certain to occur in every such case. He said the term "didelphys" was wrong. It was reasonably certain that the condition never obtained in women, and the correct title was "bicornis."

Dr. WILLETT (Liverpool) also described a case in which the non-pregnant horn did not obstruct.

Haematoma in the Abdominal Wall simulating New Growths.

Professor W. E. FOTHERGILL (Manchester) read a paper on haematoma in the abdominal wall simulating new growths, and gave an account of some of the cases which he had encountered. He gave an account of the diagnostic points and the lines of differential diagnosis. (We hope to publish Professor Fothergill's paper in an early issue of the JOURNAL.)

Mr. W. W. KING (Sheffield) described two cases in which rupture of a vessel in the abdominal parietes gave rise to acute symptoms; one case simulated torsion of the pedicle of an ovarian cyst, and the other caused continued pain of uncertain origin.

Case 1.—In an elderly woman, the subject of chronic bronchitis, acute left-sided abdominal pain followed a severe attack of vomiting; the presence of a tender swelling just above the left of Poupart's ligament at first suggested a hernia. The swelling rapidly increased in size; the patient became very ill, and vomiting was copious; the bowels acted with an enema. Twelve hours later a tumour the size of a five months pregnancy was detected in the abdomen. This was at first thought to be an ovarian cyst with torsion of its pedicle, but pelvic examination contra-indicated this possibility. As the result of an exploratory laparotomy, the "tumour" proved to be a large haematoma lying between the rectus fascia and the peritoneum. The clot was evacuated, and the patient made a good recovery.

Case 2.—A woman, aged 38, had an acute attack of epigastric pain and vomiting, which was subsequently shown to have been due to pancreatic disease. The violent vomiting caused a sudden pain in her left side, which persisted more or less acutely for three weeks, when she was sent to hospital. It was then possible to detect some bruising of the skin, which roughly followed the line of the deep epigastric vessels. In the middle of this a tender swelling was felt, which, upon bimanual examination of the pelvis, was found to bulge into the peritoneal cavity. The diagnosis of a ruptured vessel, presumably the deep epigastric vein, in the abdominal wall was therefore sufficiently clear to admit of expectant treatment. In four weeks all tenderness and swelling had disappeared. While in hospital she had a second attack of epigastric pain associated with a transient glycosuria, and marked tenderness and swelling of the pancreas; apart from this she made a good recovery.

Dr. D. DOUGAL (Manchester) described a case of carcinoma of the cervix uteri after a subtotal hysterectomy. The growth in the cervix arose two years after the operation, and the cervix was then removed without any special difficulty. Professors BLAIR BELL (Liverpool) and FLESCHE SHAW (Manchester) agreed with Dr. Dougal as to the necessity of total hysterectomy in parous women, and where the cervix had been damaged or infected. Professor W. E. FOTHERGILL read notes on a case of hydatid cysts in the broad ligament; and Dr. E. D. CROFT (Leeds) gave details of a similar case in which there were also hydatids at the lower pole of the left kidney.

At a meeting of the Chelsea Clinical Society held at St. George's Hospital on April 20th, with Dr. GORDON LANE in the chair, a discussion on the treatment of late syphilis was initiated by Professor EYRE, and continued by Dr. C. E. SUNDELL and others. It was generally agreed that the injection of salvarsan or its allies was of great benefit in the amelioration of symptoms of general paralysis and locomotor ataxia, and, in some cases, effected an apparent cure. One or two speakers laid stress on the importance of treating syphilitic women during pregnancy, even though they might show no signs of the disease. The importance of bismuth preparations was urged by more than one speaker, who rated their value, in the treatment of late syphilis, as at any rate equal to that of mercury and potassium iodide.

Reviews.

ENDOCRINOLOGY.

THE second edition of Sir E. SHARPEY-SCHAFER's authoritative work *The Endocrine Organs: An Introduction to the Study of Internal Secretion*,¹ the first half of which was reviewed in our columns two years ago (1924, i, 429), is now completed by the appearance of the second part, dealing with the pituitary, the pineal, the alimentary canal, the pancreas, and the sex glands. The pituitary occupies rather more than half the volume, the sex glands rather less than a quarter, the pancreas about a seventh, so that the pineal receives eight and the mucosa of the alimentary canal five pages. The author and his pupils have done so much on the physiology of the pituitary, and the subject is so complex and important, that a very full account is most welcome.

The anatomy, both comparative and human, is described in detail and illustrated by admirable figures. It is more than thirty years since, in collaboration with the late Dr. George Oliver, a partnership now, by the author's change of name, likely to be perpetuated by the Oliver-Sharpey Lectures at the Royal College of Physicians of London, he announced the pressor effect of pituitary extract. Since then much water has passed through filtering physiological minds, and the numerous additional observations are recorded in great profusion. For example, the pars tuberalis, which surrounds the stalk of the pituitary and covers the tuber cinereum, is of great interest in connexion with Roussy and Camus's contention that polyuria and even dystrophia adiposo genitalis are due, not to pituitary lesions, but to damage to the tuber cinereum, for these observers appear to have ignored the existence of the pars tuberalis. The section dealing with the clinical manifestations of pituitary disease gives a clear and most interesting historical summary of the subject and is enriched by illustrations which, as elsewhere in this well got up work, are admirably reproduced. The therapeutic uses of pituitary extracts are briefly but critically epitomized.

The structure and the relation of the islands of Langerhans to the ordinary alveoli of the pancreas are similarly set forth with fine pictorial assistance. It may, perhaps, be recalled that thirty-one years ago, in his address to the British Medical Association (BRITISH MEDICAL JOURNAL, 1895, ii, 341), the author suggested that human diabetes was due to pathological changes in the islands. It is now conscientiously pointed out that the word "insulin," independently employed by the author in the first edition of this work in 1916, was employed as far back as 1909 by Meyer. Another point of historical interest is the approximation of Paulesco's work in 1916 (published in 1921) to the epoch-making discoveries at Toronto. The chapter on the internal secretions of the sex glands sets out the effects of grafting and vasectomy, and the criticisms brought against Steinach's conclusions, that the "all or none" principle of excitability applies to the interstitial cells, are shown to be illusory.

Dealing mainly with physiology, but not neglecting the practical application of the rapidly increasing observations on the endocrine glands, Sir E. Sharpey-Schafer's book is a most valuable source of reference, but it is obvious that the time will soon arrive, if it has not already come, when a fresh edition of the first part will be called for by his numerous readers.

Dr. W. N. BERKELEY's *The Principles and Practice of Endocrine Medicine*² is intended for those in active medical practice. Its compactness, and the details it gives of endocrine diseases and their treatment, will appeal to many. The anatomy and physiology of the several endocrine glands are summarized by Dr. Berkeley, who devotes special though short chapters to the autonomic nervous system and to the subject of basal metabolism. The thyroid naturally receives

most attention (seventy pages), the pituitary comes next with fifty-two, and then the gonads, which receive rather more space than the parathyroids and the adrenals. Owing to the recent work on the parathyroids the relatively full account of their bearings on disease is welcome. The author supports the view that chronic parathyroid dyscrasia or insufficiency is the responsible cause of paralysis agitans, though he naturally mentions, but without much discussion, the more generally accepted responsibility of the globus pallidus system. His experience with parathyroid medication is favourable, but he failed to get any improvement in the Parkinsonism of epidemic encephalitis. Among a hundred patients treated with parathyroid one only showed an idiosyncrasy to it. The possibility of hypersecretion of the pancreas or hyperinsulism with symptoms of hypoglycaemia is raised. It is rather overstating the case to say that renal glycosuria without a corresponding rise in the blood sugar is very rare. In discussing the internal secretions of the gonads Dr. Berkeley gives some interesting references to the history of castration, and refers to Steinach's and Voronoff's work on rejuvenation, but, as elsewhere, is wisely cautious and avoids drawing conclusions from insufficient data; this is also manifest in the chapters on the interrelations of the endocrine glands and on the clinical forms of pluriglandular disease. In conclusion Dr. Berkeley's book may be recommended to busy practitioners as a useful and trustworthy guide, and, though mainly a summary, provides many references which will be useful to those specially interested in particular points.

DENTAL CARIES AMONG AUSTRALIAN ABORIGINES.

Our school children who suffer so often from dental caries and toothache may well envy the lot of the aboriginal children of Australia. Dr. T. D. CAMPBELL has recently examined the skulls of 630 Australian aborigines, representing individuals of all ages, noted the condition of their dentition, and has published his results in a book entitled *Dentition and Palate of the Australian Aboriginal*.³ His collection included a series of thirty-seven children under the age of 12, and in them not a single tooth was affected with caries. Examination of a similar number of white children in any school in Adelaide would have shown that in thirty-five of them one or more of the teeth had become carious; or, to state the result in another form, 100 per cent. of the milk teeth of the aboriginal children were sound, whereas in white children only 6 per cent. were free from caries, the condition in the schools of Adelaide being neither better nor worse than that of the schools at home. Dr. Campbell noted that the milk teeth of aboriginal children are ground down by wear, a condition rarely seen in the mouths of English children. He attributes the immunity of the teeth to caries and the freedom of the palate from narrowing to a vigorous use of the teeth; the opinion will be received with caution by those who have noted the effects which Mrs. May Mellanby produced on the teeth of young animals by feeding them on a deficient dietary.

Dr. Campbell's observations on the incidence of caries amongst adult aborigines are also of great interest. He found no caries in the teeth of young adults; it began to appear in the fully grown adults and was most frequent in the skulls of the aged, but even in them only about 1 per cent. of teeth were affected. "Caries among the aboriginal natives," he states, "appears to be essentially a disease of old age and is closely associated with extreme attrition and large erosion cavities." Caries attacks native teeth only after they have been damaged. But in natives who have grown up on the outskirts of civilization and adopted the white man's diet, carious teeth were almost as numerous as among Europeans. Dr. Campbell believes that the loss of immunity to caries by contaminated blacks is due to the nature of the white man's diet. He says:

"If the masticatory system be supplied with a diet which imposes upon the teeth and jaws the task of functioning in a

³ *Dentition and Palate of the Australian Aboriginal*. By T. D. Campbell, D.D.Sc. University of Adelaide. Publications under the Keith Sheridan Foundation. Adelaide: The Hassell Press, 1925. (Gr. 4to, pp. viii + 123; 53 plates, 20 figures.)

¹ *The Endocrine Organs: An Introduction to the Study of Internal Secretion*. Second edition. Part 2: The Pituitary, the Pineal, the Alimentary Canal, the Pancreas, and the Sex Glands. By Sir E. Sharpey-Schafer, LL.D., D.Sc., M.D., F.R.S. London: Longmans, Green and Co., Ltd. 1925. (Sup. roy. 8vo, pp. xv+xxii + 177-418; 118 figures, 20s. net.)

² *The Principles and Practice of Endocrine Medicine*. By William Nathaniel Berkeley, Ph.D., M.D. London: Henry Kimpton. 1925. (Med. 8vo, pp. xi + 368; 4 coloured plates, 56 figures. 21s. net.)

thorough and physiological manner, then the tendency will be for the maintenance of normal and healthy conditions. Modern dietaries and methods of food refinement do not provide for this, hence the present-day oral and dental degeneracy.*

To this Mrs. Mellanby might reply that it was not the softness of the diet that was at fault but its deficiency in certain substances which are needed for the production of sound enamel, dentine, and bone. The unbiased critic may suspect that both are right, each having laid hold of part of the truth.

While the Australian aborigine in his native haunts is almost free from pyorrhoëa it is otherwise as regards dental abscess. Dr. Campbell found that nearly 20 per cent. of the middle-aged suffered from alveolar abscess, while in the aged 74 per cent. were so afflicted.

The sections of Dr. Campbell's monograph which deal with the diseases and disorders of the teeth of Australian aborigines represent only a fraction of his investigations. In reality he has produced a standard treatise on the dentition, palate, and jaws of the most primitive of living peoples, one which will satisfy the requirements of the scientific dentist and expert anthropologist for many years to come. The University of Adelaide recognized the value of Dr. Campbell's investigations by conferring on him the degree of Doctor of Dental Science.

"THE MEDICAL ANNUAL," 1926.

The aim of *The Medical Annual*† is to supply a review of the year's work in the treatment of disease. It claims to be essentially a practical book. To quote the graphic introductory sentence of the preface, "Its object is to supply ammunition to the men in the firing line of the war against disease." In more prosaic language we presume that this means to hand on to practitioners the discoveries of the year and the current opinions about pathology and other sciences. Such fare might, of course, be altogether unpalatable if unskillfully served; or it might be extremely useful if sensibly dressed. *The Medical Annual* has always been carefully edited and has won a position of importance amongst medical periodicals. The present volume is similar to its predecessors in its general arrangement, and doubtless will be equally useful.

The book is essentially a dictionary, and, like all dictionaries, cannot be read systematically page by page. No reviewer, however conscientious, could wade through it from cover to cover, and we cannot pretend to have discovered all its treasures or weaknesses. But after an afternoon's browsing, sampling in a leisurely fashion anything that seemed of particular interest, we feel justified in expressing the following opinions.

The thirty-four authors who have contributed to this volume seem for the most part to have dealt with their subjects either by giving an abstract of important scientific articles contributed to medical papers during the last year, or by writing an essay on what each considers to be the up-to-date point of view of his particular subject. The latter type of contribution appears to us to be not only the most readable, but also the most instructive. No doubt the one-sided private opinion finds more opportunity of trespassing into this type of article than in the judicial abstract, but the status of almost every contributor is such as to allow it to be expected that the reader will respect his opinion as much as that of an author of an abstracted paper. It would be easy to give examples of contributions that are nothing more than summaries unaccompanied by comment of papers written for various journals during the last twelve months. Perhaps in some of these, where the main activity of the contributor appears to have been with scissors and paste, he purposely refrained from expressing a personal opinion because the time is not ripe for judgement. Passing to the second type of contribution, we should like to mention two examples of the kind of article which seems to us to be more useful. Naturally its style would not be suitable for every subject, though we are persuaded that it might have a wider application. We choose these two articles at random: there may be others with a better claim to prominence.

If we turn to the subject of food, we find an article

* *The Medical Annual*, Forty-fourth year, 1926. Bristol: J. Wright and Sons, Ltd.; London: Simpkin, Marshall, Hamilton, Kent and Co., Ltd. 1925. (Demy 8vo, pp. ciii + 616; 105 figures, 66 plates. 20s. net.)

by Dr. Savage on acute food poisoning which deals successively with the causation of food poisoning, epidemiological features, types of food poisoning, and methods of investigating outbreaks to ascertain their cause and nature. The author has succeeded in giving a brief but accurate account of all the essential features of food poisoning, incorporating into the story the important new detail of the last twelve months, but yet presenting facts in their proper relation to each other, so that the less informed as well as the expert can read the article with pleasure.

Similarly, Dr. Maclean, in his article in diabetes, though he does not pretend to cover the whole ground, yet gives a very interesting review of modern development. He quotes from important articles which have appeared recently and in many cases adds his own judgement to the extract he quotes.

Finally, we must mention that illustrations, particularly plates, seem more numerous than ever and are excellently reproduced.

THE ANATOMY OF THE BASAL GANGLIA.

PROFESSOR CHARLES FOIX and Dr. J. NICOLESCO have made an important contribution to neurology in the publication of their volume‡ on the anatomy of the basal ganglia, subthalamio region, and mid-brain, to which is added an account of the pathological anatomy of Parkinson's disease. The volume, which is beautifully produced and well bound, consists of close on 600 pages of descriptive text and some 360 illustrations, the majority being fine photographic reproductions of naked-eye and microscopic sections, but there are a number of coloured plates and diagrams.

The work is divided into three parts. The first contains a general description of the anatomy of the regions under consideration, and includes an alphabetical index of the principal nuclei and tracts, with a short definition of each. The section ends with a brief account of the embryology of the area. The second part is a systematic study of topographical sections made in three planes—vertical-frontal, horizontal, and sagittal. One series is stained by myelin stains to show the nerve tracts, and a second series by Nissl's method to demonstrate the formations in the grey masses. Accompanying the photographic reproductions are line diagrams explaining each section. The third and most important part contains a detailed description of the cell and tract anatomy of each subdivision of the region individually—corpus striatum, thalamus, subthalamio region, sublenticular region, region of the infundibulum and tuber, red nucleus, locus niger, etc. It is impossible to summarize the large amount of detailed information in each section of the book, but the whole is presented with remarkable clearness and skill. The work must prove indispensable to all concerned in the serious study of the anatomy, physiology, and pathology of these regions, which have assumed great and growing importance in recent years.

The volume concludes with a detailed description of the morbid anatomy of true Parkinson's disease. The postencephalitic Parkinsonian syndrome is excluded, though the authors agree that the localization of the inflammatory lesion in these cases is essentially the same as that of the abiotrophic and degenerative lesions of so-called true Parkinson's disease—that is, mainly in the globus pallidus and locus niger. In addition to the special changes in these situations, they find widespread changes of a senile type throughout the cerebrum, cerebellum, and brain stem. This section is particularly interesting and, like the rest of the volume, is fully illustrated.

CHEMICAL PATHOLOGY.

THE five years which have elapsed since the fourth edition of Dr. WELLS's *Chemical Pathology* was published has been a period during which biochemical studies have been attended with considerable success, and in preparing the fifth edition§ of his well known textbook Dr. Wells was faced

§ *Anatomie Cérébrale: Les Noyaux* Région pathologique de la Maladie de Parkinson. Dr. J. Nicolsco. Paris: Masson et Cie. 1925. 4 plates. 100 fr.; bound, 125 fr.

¶ *Chemical Pathology*. By H. Gideon Wells, Ph.D., M.D. Fifth edition, revised and reset. Philadelphia and London: W. B. Saunders Company. 1926. (Roy. 8vo, pp. 750. 40s. net.)

with the question of what to omit and what to add from the volume of publications on chemical questions. The chief aim of the book in the past has been to supply a reasonably complete summary of knowledge of chemical pathology within a single volume of moderate size. The advances of recent years have necessitated some increase in the size of the book, but this increase is not so great as might have been anticipated, because some of the older work has been eliminated and many chapters entirely rewritten. No doubt it would be easy to report the existing state of knowledge of the topics considered in this book in a much briefer space, but more than the minimal amount of existing evidence is included here because it has always been one of the objects of the book to serve as a guide to investigators with the hope of stimulating further researches.

Since we have already discussed the qualities of this textbook when reviewing previous editions, and since the book is already familiar to many of our readers, we need do no more than announce the fact that a further edition has been issued.

THE STUDY OF COLLOID CHEMISTRY.

It has been truly said that no complete appreciation of the characteristics of colloids can be realized without practical—that is, manipulative—experience. The English translation of MICHAELIS's book¹ is therefore a work of some importance to the numerous students of the subject. In it are described the experiments fundamental to a proper introduction to the subject. The directions for procedure are sufficiently explicit to enable the worker to choose the necessary equipment and practise the exercises given. These cover substantially the whole field of methods by which colloidal characteristics have been investigated. Beginning with the principle of serial experiments, the volume proceeds to describe precipitation from colloidal solution by electrolytes, with illustrations of the adjuvant and antagonistic actions of different ions and the effects of mutual protection and precipitation of colloids. Determination of the concentration of hydrogen ions by indicators leading to the titration of gastric juice is next studied. Following this are experiments in the optimum concentration of reactions, surface tension, osmosis, electrophoresis, adsorption, and measurement of electromotive force. The directions are accompanied by a detailed discussion of the theoretical considerations bearing on the facts, and these are set out in the clearest terms. A performance of the exercises carried out with due care will lead to confidence and will qualify the worker for independent attack on self-imposed problems. A growing number of students willing to develop a practical experience in its study are being attracted to this subject: to these this book presents an opportunity for that development. Even those who are content with the knowledge to be acquired by reading will be wise to choose this volume. The scheme of study presented leads not only to a clear understanding of the principles enunciated, but also to the direct elucidation of the reactions of importance in physiology and pathology. It is an excellent book ably translated.

NOTES ON BOOKS.

TEN years ago bilharziasis was regarded as an incurable disease of unknown etiology. To-day, thanks to the labours of Christopherson, Leiper, and others, the disease is one of the more certainly curable and most easily preventable. In various countries local investigators have elucidated details concerning the mode of spread and the best method of applying treatment. We have received for review a small book entitled *Schistosomiasis vel Bilharziasis*,² by Dr. C. G. KAY SHARP, who, as chief medical officer to the Natal Education Department, has had experience of the disease in schools in South Africa. He considers that the school is one of the best means of securing

control of the disease. The treatment of the individual at home is a useful, though not an important, contribution to public health, but in the schools mass treatment can be carried out and mass education in prevention given. This little volume, so conveniently arranged and so well written, will give to those interested, either in the medicinal or educational aspect of the case, an insight into the most recent advances in our knowledge of the subject, and can be cordially recommended, owing to its clarity, to the lay reader as well as the medical practitioner.

Pitfalls of Marriage,³ by WALTER GALLICHAN, is another of the many volumes that have been published in recent years on the problems of love and sex. Like all similar writings, it is an effort to show that the chief risks to happiness in marriage arise from ignorance of the two sexes "regarding each other's psycho-sexual emotions, desires, and needs." The theme is worked up into a series of ten short chapters, which contain nothing that is new, and in which quotations are freely made from writings and addresses that are common property in the literature of the sex problem. The author's style is clear and straightforward, without undue prurience, and will probably be appreciated by readers desirous of being instructed in what, after all, is well known to most men and women in these days of psycho-analysis and sex education.

In his little book on *Diabetes Mellitus and its Dietetic Treatment*, a new edition⁴ of which has recently reached us, Major B. D. BASU, I.M.S.(ret.), advocates treatment by diet. He is strongly in favour of a purely vegetarian diet, and gives advice as to the various forms of such diet which he considers useful. Glycosuria is a very common disease among the upper and middle classes of Indians, especially Bengalis of middle age. The volume is intended for the patient rather than for the medical profession, and the advice given should be of service to those who will take the trouble to follow it with care. A book which has gone through thirteen editions in sixteen years (1909 to 1925) has evidently found a public. There are too many misprints.

² *Diabetes Mellitus and its Dietetic Treatment*. By B. D. Basu, Major, I.M.S.(ret.). Thirteenth edition. Bahadurganj, Allahabad: The Panini Office. 1925. (Cr. 8vo, pp. ii + 94. 2 rupees.)

THE UNIVERSITY OF LONDON.

WE announced at the end of March (March 27th, p. 583) that the report¹ of the Departmental Committee appointed by the Board of Education on the University of London had been issued, and gave some brief indications of its general character. The report is, however, a very important document, making proposals for important changes in the government of the University of London; and in the interests of London education, and of medicine in particular, we think it advisable to give a somewhat detailed criticism of its recommendations.

The Departmental Committee was appointed by the then Minister of Education, Mr. Charles Trevelyan, in October, 1924, with the following terms of reference:

"To consider the Final Report of the Royal Commission on University Education in London dated March 27th, 1913, and having regard to present circumstances and after consultation with the persons and bodies concerned, to indicate what are the principal changes now most needed in the existing constitution of the University of London and on what basis a Statutory Commission should be set up to frame new Statutes for the University."

The Committee consisted of Lord Ernle, as chairman, Sir Robert Blair, Mr. H. L. Eason, Mr. H. B. Lees-Smith, Sir Henry Miers, Professor A. F. Pollard, Sir L. A. Selby-Bigge, and Miss K. T. Wallas. Lord Ernle resigned from the committee in the early part of 1925 and was succeeded by Mr. Hilton Young as chairman. The question of the site was expressly excluded from the reference to the Committee.

The Committee took a large amount of evidence from representatives of institutions, schools, and other bodies, and also from a number of individuals. It held forty-six meetings, of which twenty-eight were, in the main, devoted to the taking of evidence, and the remainder to deliberations and the drawing up of the report. The Committee appears to have taken a considerable amount of

care in asking for evidence from bodies and institutions directly or indirectly concerned with university education in London and from individuals whom it considered to have valuable knowledge on the same subject.

The report is signed by all the members except Mr. Lees-Smith, who dissents from the recommendations with regard to the establishment of a University Council.

The report discusses in many places the report of the Haldane Commission of 1913. In many respects the members of the Committee disagree with the recommendations of that Commission, but in others they agree. It will not be necessary to indicate in detail the various points of agreement and disagreement, but there is one conclusion of great importance which should be stated now; it is:

"we would emphatically record our conviction that on geographical as well as on other grounds there is no justification for more than one university in London.

In the body of the report they state that the Act of 1898, under which the present University was constituted, "is conspicuously lacking in a principle which we regard as essential to a true conception of the University of London." This is that the University cannot hope to realize its full powers until its colleges and constituent units can take a full share in its government. Up to the present, in the main, the colleges and constituent units of the University have only had representation on the supreme governing body or Senate by indirect methods. In order to secure this vital principle they recommend that statutory changes be made to ensure adequate institutional representation on the Senate. The present organization of the University assumes that there are three main activities in the University: (a) the teaching side; (b) the external side; and (c) the extramural side. At the present time there are three statutory standing committees of the Senate—the Academic Council, the Council for External Students, and the Board to Promote the Extension of University Teaching—which roughly undertake the duties which concern the three units mentioned above. The report states that many problems require consideration which are not primarily the concern of teachers or graduates as such but of the institutions, such as the various colleges which form parts of the University. The Committee holds strongly the view that this institutional and college element is so important that it ought not only to have representation on the Senate, but that a special standing committee of the Senate should be devoted to these interests. On this account the majority of the members recommend the formation of a new council to be called the Collegiate Council. Attention is drawn to the fact that the Government gives to the University of London and the various colleges and institutions which help to form it, through the University Grants Committee, an annual sum of £377,000 for university education in London. This sum is not given as a block grant to the University of London to be distributed by it to the individual institutions of the University, but separate grants are paid to the central administration of the University, to each of its two incorporated colleges (University College and King's College), and to twenty schools, of which eleven are medical schools. From this point of view they consider this state of things to be clearly unsatisfactory, in that the University of London is in no real sense master of its own house or capable of enforcing a policy of its own. They say that "In guiding the development of its colleges and schools the University has less reality of power than outside grant-giving bodies such as the University Grants Committee or the London County Council." This they consider a great indignity for the great University of the capital city of the Empire, and consequently they recommend that in the proposed amended constitution of the University the allocation and distribution of grants coming either from the Government through the University Grants Committee, or from the London County Council or from other bodies, should be in the hands of the University authorities. The Commissioners consider (Majority Report) that the present Senate is too large, too unwieldy, and contains too many representatives

of internal interests to fit it to be a supreme body in the allocation and distribution of funds.

Finance.

With this conclusion we are in agreement. In the past the Senate of the University has taken very little active and direct part in the initiation of new projects of education which are of great importance to London and London education. In most instances proposals either for reform or for the initiation of new projects have come from institutions or individuals directly connected with them. At the present time the Senate consists in the main of two halves, which may be designated the internal and the external. These are so evenly balanced that in practice it has been found almost impossible to carry through any measures of reform or change whenever there has been any serious difference of opinion. This is very well illustrated by the question of the proposed site for the University. As is well known, some years ago a site was bought by the Government and offered to the University under certain conditions. For several years this matter has been, one might say, under continuous discussion in one form or another, and now, owing to the fact that the University has not been able to accept the offer from the Government, this offer has recently been withdrawn and the site again offered for repurchase to the Duke of Bedford, from whom it was originally bought and to whom it has now reverted.

In connexion with this aspect the Commissioners say:

"We have no doubt that there should be in the University of London a body so constituted as to qualify it to negotiate with grant-giving bodies, to engage with them in the final and effective discussion of the University budget and to allocate the grants which result from that negotiation and discussion."

They express the hope that the actual effect of a change from allocation of grants by the University Grants Committee and other bodies to their allocation by the University will not be exaggerated. It is not to be supposed, they say, that the first act of the University would be to tear up the old allocation and construct an entirely new one. In fact there is little doubt that in the earlier stages of such a change the practice of the University Grants Committee in the past would be closely followed.

University Council.

As regards the government of the University, they say: "We are satisfied that all functions of government in the University of London cannot be constituted in a single body," as is done at the present time with the present Senate. They reject that feature of the Haldane Report which put supreme executive power in the hands of a small body predominantly unrepresentative of University interests. They say: "It would be idle to attempt to constitute a Senate completely representative of all the varied institutions and interests of the university," and they also say "it would be unwise to ignore the fact that the larger the body the less effective it is likely to be as an executive instrument." They do not regard such a large assembly as the Senate must invariably be as suitable to negotiate with public grant-giving authorities on behalf of the University and its colleges. In addition they do not think that the Senate, or any committee of the Senate, should exercise final authority in financial matters. On account of these considerations they recommend (Majority Report) that there should be a *University Council* to determine the allocation of funds for the execution of University policy and generally to exercise control of finance; and that this council should consist of sixteen members—the Chancellor, the Vice-Chancellor, the Chairman of Convocation, six members elected by the Senate from their own number, four representatives appointed by the Crown, two representatives of the London County Council, and one co-opted member. They recommend that this council shall have power to co-opt one member because they think it would be advisable for the council to be able to secure the services of one member well versed in financial matters or identified with interests with which the University is, or may be, financially concerned.

The duties of the council suggested are "to control the finance of the University and in particular to have final

authority in the allocation of University funds, but in dealing with financial matters directly affecting educational policy, it should give the Senate full opportunity of reporting." They recommend that the council shall have the power to negotiate with and receive money from grant-giving bodies for the University as a whole and for any schools of the University, including colleges. They also recommend that the council should appoint its chairman from among its own members.

The formation of such a council will transfer from the Senate to it the supreme decision in all financial matters and in all matters which concern generally University policy in London. It will be seen, however, that it is not suggested that this council should take action in connexion with educational matters unless it has previously had a report from the Senate on the subject. Taking into consideration what has happened in the past and the difficulties which are invariably experienced in a large body as numerous as the present Senate in carrying out administrative functions and in initiating progress, it appears to us that the creation of a council of this kind, which in some respects resembles the Board of Regents who control the finances and general university policy in many American universities, would be an excellent solution. The University is so comprehensive as regards its colleges, institutions, and educational interests that it does not seem wise to leave to a body which is composed to a great extent of representatives of either institutions or educational interests the final decision as regards the important points of University finance and University policy. A smaller body, such as the council suggested, would, in our opinion, be in a position to carry out these duties much more effectively and with less chance of results being influenced by interested institutions or individuals. Some have argued that the formation of a council of this kind would necessarily place the supreme control of University policy and progress in the hands of people who at first hand might not be familiar either with the University of London or the requirements of University education. We cannot think, however, that with the proposed constitution such a result is likely to follow; in fact, we feel assured that the Crown and other bodies concerned will appoint to the council persons who are well suited for carrying out the duties of such an important body.

The Senate.

The Departmental Committee recommends that the Senate should consist of the Chancellor, Vice-Chancellor, the Chairman of Convocation, sixteen members elected by the Faculties, sixteen members elected by Convocation, one representative each from seven colleges (University College, King's College, Imperial School of Science and Technology, School of Economics, Bedford College, East London College, and Birkbeck College), two representatives of general medical schools elected by the medical schools, and five members to be co-opted at the discretion of the Senate. Two, but not more than two, may be appointed to represent schools of the University not otherwise directly represented on the Senate. They recommend that the Senate should elect the Vice-Chancellor, and, in so doing, should not be restricted to choosing one of its own members. If a person is appointed who is not a member of the Senate, he shall be a member of the Senate during his term of office as Vice-Chancellor.

As regards the duties of the Senate, the report says

"that the Senate, subject to the final decision of the council, shall control the educational work of the University and shall also have power to delegate the performance of such duties as it thinks fit to its standing committees and other bodies."

The Senate thus constituted will consist of forty-eight members, or forty-nine in the case of a Vice-Chancellor being elected from outside. The present Senate consists of fifty-six members, so that there would be a small diminution. This is, in the main, due to leaving out two members appointed by the Royal College of Physicians and two by the Royal College of Surgeons and the members appointed by the law institutions (Lincoln's Inn, Inner Temple, Gray's Inn, and the Law Society). Originally, when the present Senate was constituted, it was thought that the inclusion

of various representatives of the law institutions might result in the formation of a great school of law within the University. This, however, has not happened, and, in fact, all attempts to form such a school with the co-operation of the law institutions have failed. As regards the representation of the Royal College of Physicians and the Royal College of Surgeons, it was thought that possibly closer working arrangements of some kind or other might have been established between the two great medical licensing bodies in London and the University. Nothing, however, has been done in this matter, and so, judging from the analogy of the law, the Commissioners have not recommended that these four representatives should be continued in the new Senate. From the point of view of medical education and licensing in London, we cannot help thinking that in future there must be some form of very close co-operation between the University of London and the Colleges of Physicians and Surgeons. So far, however, all suggestions for closer connexion and working have not led to progress, and we only hope that in the future the Council of the University, when constructed, will be able to promote a more active co-operation than exists at present. At the moment all students in medical schools in London have, in the main, to pass the examinations of the Colleges of Physicians and Surgeons as well as those of the University of London for their qualifications. To anyone who has had practical experience, especially of final examinations, it seems that the same ground is being gone over twice without any real reason.

One very important difference in the proposed duties of the new Senate and those of the old is that it shall have power to delegate the performance of such duties as it thinks fit to its standing committees and other bodies. In the past this has not been possible. Consequently the work of the Senate has been to a great extent that of registering and confirming the works of various councils, committees, and boards of studies. The report recommends the establishment of five standing committees—Academic Council, Council for External Students, Collegiate Council, the University Extension and Tutorial Class Board, and the Matriculation and Schools Examination Board. These standing committees it is recommended should have power to delegate executive power to subordinate bodies. This ought to facilitate the administrative working of university education. It is also recommended that the Senate should have power to appoint standing and other committees and delegate executive functions to them, provided that such powers and duties do not interfere with the powers and duties entrusted by statute to some other body. It is recommended that there should be right of appeal to the Privy Council. The report specifies in particular that the Senate should have power to appoint bodies to act as Boards of Studies in respect of special subjects, and in appointing these bodies shall not be limited by statutes governing the constitution of Boards of Studies.

Academic Council.

The report recommends that the Academic Council consist of the Vice-Chancellor, sixteen members of the Senate elected by the Faculties, and nine other persons, who need not be senators, appointed by the Senate. In appointing these nine other persons it is advised that the Senate shall have regard, amongst other things, to important subjects of study not represented on the Academic Council, and shall consider any reports and nominations submitted by Boards of Studies.

Council for External Students.

It is recommended that the Council for External Students shall consist of the Vice-Chancellor, sixteen members of the Senate elected by the Convocation, and nine other persons, who need not be senators, appointed by the Senate.

Collegiate Council.

This is an entirely new body not represented in the present constitution of the University. It is advised that it should consist of the Vice-Chancellor, the Principal, seven members of the Senate appointed by the seven schools already mentioned, two members of the Senate appointed

by the medical schools and such other representatives of schools of the University as the Senate may determine, provided that if the Senate determines to add other members, and groups a number of institutions for representation, the grouped institutions shall themselves elect the representatives allotted to them. It is recommended that the Principal of the University should be the chairman of the Collegiate Council in virtue of his office, and that the duties of the Collegiate Council should be to advise the Senate on institutional and inter-institutional matters, and exercise such executive functions with regard to inter-institutional matters as the Senate may assign to it. It appears to us that the establishment of a Collegiate Council of this kind is a most important step towards progress. In the past there has never been an effective method whereby inter-institutional or inter-collegiate educational matters could be regularly discussed and the decisions so attained become effective as regards the important principles in connexion with education in London. By making the Principal chairman of the Collegiate Council it is thought that he will have such a knowledge of individual collegiate institutions that he will be able to help them materially in their deliberations and in many cases give them very valuable advice.

The University Extension and Tutorial Classes Board.

In the establishment of the University Extension and Tutorial Classes Board, which would be appointed by the Senate, it is recommended that a condition be made that it should include members of the Academic Council, Council for External Students, and Collegiate Council, together with some representation of the interests with which the Board would be concerned.

The Matriculation and Schools Examination Board.

The report recommends the establishment of a Matriculation and Schools Examination Board, to be appointed by the Senate, subject to the condition that it shall include members of the Academic Council, the External Council, and the Collegiate Council, together with some representation of the interests with which the Board will be concerned.

The report further recommends that the Senate should appoint a Board of Faculty in the Faculties of Art, Science, and Medicine, and that it should have power to appoint a Board of Faculty in any other Faculty. It is recommended that one of the duties of a Board of Faculty, or of a Faculty where no Faculty Board exists, shall be to make recommendations to the Senate as to the composition of Boards of Studies, after having considered the suggestions, if any, of Boards of Studies, as to their own composition.

An important improvement as regards education and administration within the University will be effected if this recommendation is carried. It will be seen that the Board of Faculty will have power to communicate direct with the Senate, instead of, as at the present time, having to send its recommendations through the Faculty itself. In medicine, especially, the Faculty is so large that it is often impossible from a practical point of view to make representations to the Senate within a reasonable time.

As regards schools of the University, the conditions governing the admission or readmission of an institution as a school of the University would include the following:

(a) That the University is satisfied with the constitution of the governing body of the institution and with the statutes under which it is governed.

(b) That the institution recognizes the right of the Council of the University to negotiate, on the institution's behalf, with public grant-giving bodies, and to receive and allocate the grants available for university education in London.

(c) That the institution undertakes not to issue a public appeal for money without first obtaining the consent of the Council of the University, and to consult the University before accepting benefactions to which conditions are attached.

(d) That the institution relinquishes to the University the appointment of such of its principal teachers as the Senate may determine.

In connexion with these recommendations the medical schools of London, or at least some of them, will find, in all probability, that it is necessary in some way or other

to alter their constitution or their government. At the present time many medical schools are governed by a committee of teachers, which has no corporate constitution, and which, in many cases, is unable to communicate directly with the University owing to the fact that the medical schools in many instances are part and parcel of hospitals, and any negotiations on educational matters have to be carried on through lay members of the governing body. It is not clear from the recommendation (d) as to which teachers shall be included on the list of those whose appointment has to be approved by the University. Difficulties may arise if that recommendation is adopted in its present form in connexion with the present method of appointment of heads of clinical units. In practice these appointments are made usually conjointly by the University and the hospital and the authorities of the medical school. There is little doubt, however, that practical difficulties in connexion with these appointments can readily be settled in the drafting of Statutes by the Commissioners if and when appointed.

Examinations.

It is recommended that the Senate should have power to approve for degree purposes syllabuses and courses of instruction submitted by incorporated colleges or schools of the University and to conduct examinations for university degrees related to such syllabuses and courses of instruction. Such powers as these may, in the future, have great influence in connexion with education in London. Difficulties may be experienced in ensuring that courses of instruction and examinations represent the same standard of education and knowledge.

Principal.

The report recommends that a Principal of the University should be appointed by the Senate after consideration with the Council, and that he should have unrestricted rights of attendance and speech at all meetings of the Council, the Senate, and the standing committees of the Senate, and that it shall be his duty to assist them with his advice. In addition he shall be chairman of the Collegiate Council, but shall not be a member of the governing body of any school of the University. In our opinion this recommendation is most important, and we quite agree with the suggestion that the title of the principal administrative officer should be "Principal" and not "Principal Officer," as at the present time. Many may advocate that the offices of Principal and Vice-Chancellor ought to be combined. In the University of London, which comprises so many educational institutions, it is not, in our opinion, feasible or practicable to combine the duties of these two offices in one individual. We think it advisable also that the various members of the Senate or persons taking a very important part in education in London should have the opportunity of being placed at the head as Vice-Chancellor (under the Chancellor).

The recommendations to which we have referred as a Majority Report are signed by all members with the exception of Mr. Lees-Smith. He has presented a Minority Report in which he disagrees with the recommendation for the establishment of a University Council, which is to be charged with the general conduct and which is to deal with the finance of the University. He thinks that the Senate ought to be the supreme body, and that a statutory "Finance Council," with the same membership as that proposed in the report for the supreme University Council, should be formed. The duties of this Finance Council, in his opinion, would be to allocate the public grants made to the University, subject to any general policy already laid down by the Senate. He thinks it could be given, by standing order, formal power to negotiate with grant-giving bodies, subject to general directions given by the Senate, and, whether formally or not, would in fact conduct the negotiations.

With this opinion, expressed in the Minority Report, we do not agree. We feel strongly that the supreme governing body of the University ought to be comparatively small, such as it is proposed in the Council, and that it ought not to be in the hands of a large body such as the Senate.

British Medical Journal.

SATURDAY, MAY 22ND, 1926.

THE UNIVERSITY OF LONDON.

THE affairs of the University of London do not seem to make much progress, unless it be backward. Certain things, however, have happened. In the first place, the Duke of Bedford has decided to exercise his right to repurchase from the Government the Bloomsbury site, which was offered to the University by Mr. Fisher when President of the Board of Education, on the terms agreed upon at the time of its purchase by the Government. In the second place, the Senate and Convocation of the University have carried resolutions rejecting the chief recommendation of the Majority Report of the recent Departmental Committee—namely, the creation of a supreme Council; both resolutions have been communicated to the President of the Board of Education, and the Senate has appointed a committee to consider what alterations are needed in the organization of the University.

The Senate as at present constituted is a large body containing only a small minority acquainted with the needs of the medical schools of London, which collectively form the largest and most active faculty engaged in teaching in London. Our information is that medical opinion in the University is not in accord with that now expressed by the Senate and by Convocation. We publish elsewhere in this issue an article reviewing the report of the Departmental Committee, and we believe that the medical teachers in London would be more nearly in sympathy with the opinions there set out. We understand that the Board of the Faculty of Medicine, the Committee of Medical Members of the Senate, and the Board of Advanced Medical Studies have given definite expression to their views in favour of the recommendations in the Majority Report of the Departmental Committee. That report recommended the creation of a supreme Finance Council and the appointment of a smaller Senate, the latter to have power to delegate the performance of such duties as it thought fit to its standing committees and other bodies. As is explained in the article, the standing committees would be five in number—the Academic Council, the Council for External Students, the Collegiate Council, the University Extension Board, and the Matriculation and Schools Examination Board. These again would be authorized to delegate executive power to subordinate bodies, and if this were done the administrative working of university education in London would be greatly facilitated. At present the colleges and constituent units of the University have no direct representation on the Senate, which is the supreme governing body, although many of the problems urgently calling for consideration directly concern the colleges and institutions which form part of the University. The Departmental Committee consequently recommended the establishment of a Collegiate Council, to consist of representatives of the seven chief colleges in London, of representatives of the medical schools, and of such other schools of the University as the Senate might determine, these representatives being chosen by the schools and not

nominated by the Senate. Such a body, which would meet under the chairmanship of the Principal, would be able to discuss, among other matters, inter-institutional education questions.

The report of the Departmental Committee undoubtedly affords a new point of departure. It remains to be seen what course the President of the Board of Education will take, for the whole matter is now, in view of the recent action of the Senate and Convocation, once more in his hands. Lord Eustace Percy has a great opportunity, for if he acts in accordance with the recommendations of the Majority Report of the Departmental Committee he will, we feel confident, have a large measure of approval and support, especially from the medical schools and colleges in London. The two large medical colleges of St. Bartholomew's and Guy's have already expressed themselves in favour of the recommendations of the Majority Report of the Departmental Committee.

BARBITURIC DERIVATIVES AS DANGEROUS DRUGS.

ON February 24th, 1925, Sir John Anderson took the chair at a conference of representatives of the Home Office, the Ministry of Health, the pharmacists, and the British Medical Association, held to discuss the measures necessary to obviate the dangers arising to the public from the unrestricted sale of veronal and other drugs derived from barbituric acid. The Home Office experts produced copious evidence of deaths caused, particularly by veronal, sometimes suicidal, but perhaps more frequently from an accidental overdose when taken for sleeplessness. It was stated that in London experience showed that in this respect veronal was the most dangerous drug in the *Pharmacopoeia*. The representatives of the British Medical Association agreed that it was desirable to prohibit the retail sale of these drugs to unauthorized persons except on a medical prescription, but the chemists' representatives were opposed to this unless doctors were at the same time forbidden to supply the drugs, even to their own patients, and were required to order them by prescription, except in emergency or in districts where no chemists were available. To this the Association representatives took strong exception as being an interference, on a side-issue, with an undoubted right of dispensing doctors, and especially, as there was no evidence of any untoward effects arising from the use of the drugs supplied in this way.

The Home Secretary has now taken steps to make regulations under Part III, Section 8 (2), of the Dangerous Drugs Act, 1920, to include amongst the drugs therein specified: "Diethyl-barbituric acid and other alkyl, aryl, or metallic derivatives of barbituric acid, whether described as veronal, proponal, medinal, dial, or by any other trade name, mark, or designation, and any preparation, admixture, or other substance containing any of them." The effect of the new regulations is fourfold. In the first place, they will make it unlawful to supply by retail any of these drugs except (a) to a duly qualified medical practitioner, (b) for use in hospitals or similar public institutions, (c) to persons authorized by the Secretary of State, (d) on or in accordance with a prescription given by a duly qualified medical practitioner. In the second place, prescriptions for the drugs must be dated and signed by the practitioner and bear his address, and they must specify the name and address of the patient and the total amount of the drug to be supplied on the prescription. In the third place, where doctors dispense

their own medicines and make an entry in their day-book with particulars of the drug and the name and address of the patient and the date of supply, no further record is required. There is no obligation to keep any record of purchases of these drugs. Fourthly and lastly, the drugs may not be supplied more than once on the same prescription; provided that, if the prescription so directs, the drugs may be supplied on more than one but not exceeding three occasions, as directed in the prescription, at intervals to be specified in the prescription.

The Council of the British Medical Association carefully considered the whole question at its meeting on April 7th, 1926, and, being convinced of the necessity of restricting the sale of these drugs, decided to raise no objection to the issue of the new regulations, believing that they would cause the minimum of inconvenience to members of the medical profession compatible with the objects to be attained.

THE "BRITISH MEDICAL JOURNAL" AND THE STRIKE.

CIRCUMSTANCES beyond our control made it necessary that the last issue of the *BRITISH MEDICAL JOURNAL* should appear with two dates—"May 8th and 15th, 1926." As we explained briefly in an annotation at page 838 of that issue, the material was in course of preparation for printing when the general strike stopped all work at the machine printers' office (where the *JOURNAL* is printed on rotary presses) on the morning of Tuesday, May 4th; and we have now to add that work was not resumed there until the afternoon of Monday, May 17th. Thus a fortnight passed during which machine printing was at a standstill. The compositors in our own printing department at Tavistock Square (where the type for the *JOURNAL* is set) were called out by their trade union on May 6th; they returned to duty on May 13th, but owing to failures of electric power only a limited amount of mechanical typesetting could be undertaken, and difficulties from this and other causes still continue. We had hoped that after the calling off of the general strike on May 12th the work which stopped at the machine printers' office on May 4th would be taken up again rapidly, and that all copies of our last issue would be printed and distributed by the end of last week. This hope was not fulfilled, and publication was delayed until May 18th. The result of all these breakdowns and disappointments is that members of the British Medical Association and subscribers to the *BRITISH MEDICAL JOURNAL*, instead of receiving separate *JOURNALS* for May 8th and May 15th, have received this week a belated issue bearing the dates May 8th and 15th, and will receive two or three days afterwards another *JOURNAL*—our present issue—dated May 22nd, which falls short in several respects of what we should wish to give our readers. Nevertheless, we feel sure that these shortcomings will be overlooked. Another effect of the strike which may be mentioned here was the cancellation or postponement of all the meetings of committees and subcommittees of the British Medical Association which had been fixed for the present month. The Medical Secretary's department has notified these changes of plan to all concerned. The Council meeting arranged for June 9th will be held on that date.

TISSUE CULTURE.

THERE is no need to emphasize the importance of a study of the inherent capacities of cells as regards their power of growth, differentiation, and dedifferentiation; the study is rendered possible by the method of isolating groups of cells from their normal surroundings and their vascular and nervous connexions in the body and either regrafting them

into the living organism or cultivating them in artificial media *in vitro*. Good work has already been done in this direction, not the least interesting being the observation that two distinct types of growth may be distinguished in tissue cultures *in vitro*. In one type, termed by Thomson "uncontrolled," the growth is irregular, showing no tendency to the production of body structures; in the other, "controlled," type the proliferating cells group themselves in definite forms, reproducing more or less closely some organ or part of some organ of the body. This capacity for self-differentiation has been proved by Braus, Harrison, and others to exist in the undifferentiated limb-buds of amphibia; Thomson observed that the whole chick embryo increased in size during cultivation *in vitro*; Chlopin has described a progressive differentiation of various mammalian tissues; and Maximow has observed an organotypic growth in portions of rabbit embryos. Considering the interest of the subject, however, this type of growth has at present received relatively little investigation. A contribution to our knowledge has recently been made by Strangeways and Fell in a communication to the Royal Society on experimental studies on the differentiation of embryonic tissues growing *in vivo* and *in vitro*. They succeeded, by an improved technique, in cultivating *in vitro* the undifferentiated limb-buds of fowl embryos of seventy-two to eighty hours' incubation, and were able to trace the formation of cartilage, white fibrous tissue, and typical epidermis in the mass of undifferentiated cells. Further, in some of the experiments it was possible to distinguish the early stages in the development of a normal limb-skeleton, the cartilage assuming an axial arrangement in the limb-bud and becoming subdivided into two and sometimes three segments. In the grafting experiments, in which the limb-bud was inoculated into the subcutaneous tissue of the chick, nothing corresponding to the normal limb-skeleton was obtained, a result which is sufficiently explained by the migration of leucocytes into the limb-bud and other modifying influences of the surrounding living tissue. Two main differences are noted by the authors between the histological composition of the growths *in vitro* and that of the normal limb—namely, the absence of differentiated muscle and the absence of bone; but no suggestion is offered as to the cause of this interesting fact. The successful results obtained in these experiments will doubtless stimulate further research in this subject.

ENCEPHALITIS LETHARGICA.

THE increase in recent years in the number of cases of encephalitis lethargica is disquieting, and is noted in the reports of some medical officers of health. Thus, Dr. R. Veitch Clark states that the number of notified cases verified in Manchester during 1924 was 244, and that the deaths numbered 52. In view of the unfortunate mental and moral disabilities which not infrequently follow in its train, and its very high mortality, especially in the young, a fuller knowledge of its epidemiology is urgently called for, and inquiries, both central and local, have been set on foot. An extensive inquiry into the 1924 epidemic in Manchester has been made by Dr. W. St. Clair McClure, whose interesting and instructive report accompanies that of Dr. Veitch Clark. Dr. McClure reports that during 1924 282 persons were notified as suffering from this disease, and extended observations resulted in 244 of them being accepted as true cases. The remainder included cases of influenza, tuberculous meningitis, cerebro-spinal fever, cerebral abscess, bronchopneumonia, chorea, and typhoid fever. In the majority of cases the diagnosis was unmistakable, but in an infant it was not so easy, and in old people symptoms due to senility and to cerebral softening caused some difficulty. Examination of the cerebro-spinal fluid had proved of the greatest value in excluding

meningitis. Persons of both sexes were attacked with almost equal frequency. All ages were attacked, but the incidence was heaviest upon those under the age of 20. School attendance was not found to have any noticeable influence upon the incidence. It was not until the epidemic of encephalitis had subsided that influenza of a severe type began to prevail. Special inquiry and study had produced no evidence of the interrelationship of these diseases; nor was the relationship of epidemic hiccup to encephalitis definitely determined. Hiccup might occur as one of the symptoms of encephalitis. In Manchester an epidemic of hiccup preceded the encephalitis epidemic. The attacks consisted of persistent hiccup lasting three to ten days, unaccompanied in the majority of cases by other symptoms. So far as was known, none of the patients so affected had afterwards developed post-encephalitic symptoms. There was no definite evidence that the two affections were associated, although such a possibility was not excluded. In regard to the initial symptoms of encephalitis lethargica, vomiting occurred at the beginning of the illness in 10 per cent. of cases, and headache in 36 per cent. Pronounced lethargy, with or without nocturnal insomnia, was present in 75 per cent. Insomnia and delirium without lethargy were a marked feature in about 30 per cent. Paralysis of one or more cranial nerves occurred in 40 per cent. of cases, nystagmus in 10 per cent., and diplopia in 44 per cent. Twitching movements simulating chorea occurred at the beginning of the illness in 31 per cent. of cases. In a considerable number of cases diplopia and some drowsiness were the only symptoms observed. It was considered too soon as yet to determine the end-results. Dr. McClure examined 55 patients whose illness had begun six months previously. Of these 19 were totally incapacitated, 26 partially so, and 10 had recovered. During 1920 and 1921 50 cases of encephalitis had occurred. Of these, 23 had died, and examination of the 22 survivors revealed total incapacity in 5, the disease rapidly progressing towards complete helplessness; 7 cases had recovered, and the remaining 10 were mostly able to follow their employment. Dr. Eustace Hill, medical officer of health for Durham County, refers to the remarkable increase of the notifications of encephalitis—from 7 cases in 1923 to 110 in 1924. This he ascribes partly to better diagnosis; 44 deaths occurred, compared with 11 in 1923. Dr. Hill believes that the disease is spread by mild unrecognized cases or by carriers.

RADIUM TREATMENT IN GYNAECOLOGY.

THE annual report for 1925 on radium treatment at University College Hospital, London, prepared by Dr. Leslie H. Williams, has been issued. It refers mainly to cases of cancer of the cervix and of the body of the uterus, and to menorrhagia at or about the menopause. As it is but four years since this treatment was instituted there are not yet any "five-year cures." Of 46 cases, inoperable when first seen, only 4 are cures, and of these 3 are of but two years' duration and 1 of one year. Six other cases are still alive, but with recurrence of the disease, and 36 cases have died. In all cases the evidence goes to show that the effect of radium was to improve vastly the patient's general condition for some months. Of 9 operable cases of carcinoma of the cervix 5 remain apparently cured, but the duration of the cure does not exceed twenty-seven months in any one case; 3 are alive with recurrences, and 1 is dead. Of 17 cases in which radium was combined with the Wertheim operation, 9 are alive and well, 6 of them for more than three years after the first treatment. The use of radium in cancer of the body of the uterus has proved thoroughly discouraging. In menopausal haemorrhage it is regarded as an "infallible cure." The value of radium treatment for fibroids is still a disputed question, but at

this hospital the results on the whole have been satisfactory.¹ The report is full and frank, and provides material of value in the gradual formation of opinion as to the use of and indications for radium.

HOUSES OF PITY.

Dr. JOHN MORRISON HOBSON is already known as a writer about Surrey, and we may venture to surmise that it was his interest in Whitgift's Hospital in Croydon which has led him to study the history of other charitable institutions for the old and needy.¹ As he points out, the word "almshouse" is only a corruption of the Greek word meaning pity, and the almshouses which are scattered up and down this country may well be called by the name derived from the Latin *piefas*, for they were mostly erected as much from motives of piety and regard for the founder's own soul as of pity for the bodies of the poor. Beginning with a chapter on lazaretto-houses, which are now happily obsolete, Dr. Hobson proceeds on a territorial plan, county by county, to refer to all the almshouses of which he has found records, and to describe those which are still in existence. It is a remarkable fact, to which he draws attention, that the favourite number with founders of such charities was thirteen. Again and again we find in this book that number as the sum of the original poor brethren. As he remarks, it was obviously considered a lucky number, because it was that of the company who sat down to the Last Supper. Latter-day superstition, which is so much more rampant in the twentieth century than it was in the Victorian age, has made thirteen an unlucky number, because the first to rise from a dinner party of thirteen was likened to the Iscariot, but there was nothing of this in the ages of faith when many of our houses of pity were founded. Many of these, alas! have lost their endowments by the fault of fraudulent or careless trustees and negligent public bodies, but it is comforting to think that those which remain are well and honestly administered, and that even such abuses as those at Rochester and Winchester, of which Trollope pointed the moral in *The Warden* (of Hiram's Hospital), have disappeared, and cannot be revived under the vigilant care of the Charity Commissioners. Naturally, Whitgift's Hospital occupies more space in this book than any other single charity, but very many are adequately described and illustrated by charming photographs and reproductions of old prints. We congratulate Dr. Hobson on the production of a beautiful book and a scholarly study of his subject, which redounds to his credit and does honour to our profession.

MODERN ENGLISH.

MANY of us have hardly yet recovered from the shock which our complacency suffered by a study of *The King's English*, in which the Fowler brothers exposed the mistakes of some of the best known writers and of the editors of journals of the first class. At the same time, although their criticisms made one almost despair of writing correctly, they did not fail to point out the way of improvement, by which we may hope to have profited. The *Concise* and the *Pocket Oxford Dictionaries*, by the same authors, followed, and added to the services rendered by them to the literary public. Unhappily, Mr. F. G. Fowler fell a victim to tuberculosis acquired on military service before he could take part in the actual writing of yet another book, *A Dictionary of Modern English Usage*,²

¹ *Some Early and Later Houses of Pity.* By John Morrison Hobson, M.D., B.Sc. London: G. Routledge and Sons, Ltd. 1925. (Med. Rev., pp. 21 + 199; 40 figures. 10s. 6d. net.)

² *A Dictionary of Modern English Usage.* By H. W. Fowler. Oxford: The Clarendon Press; London: H. Milford, Oxford University Press. 1926. (Cr. 8vo, pp. viii + 742. 7s. 6d. net.)

which has just been published. This book is likely to be as useful as either of its foregoers. It consists of a large number of essays on the meaning and uses, including pronunciation, of English words, arranged alphabetically, but in the case of some important subjects a number of words are to be found under one heading. For instance, the reader who seeks information on "vers libre" will find himself referred to "technical terms," under which heading he will find an essay of thirty pages which contains—arranged alphabetically within it—many examples of kinds of versification, as well as rhetorical, grammatical, logical, and other terms used in modern English. This article and others, such as those on pedantic humour, misquotation, battered ornaments, and elegant variation, will repay study. "Meticulous" has more than a page to itself, the tenor of which may be guessed from the opening sentence: "What is the strange charm that makes this wicked word irresistible to the British journalist?" The elegant variationist gets some hard knocks in the article on "Case" for his slipshod and unnecessary use of "in the case of," whereas the usefulness of the word in its right place is not disputed. "False quantity" includes consideration of some medical terms, and the attitude of the author towards pedants is reflected in its closing sentence, which, moreover, has a medical interest. Thus: "Let the scholar plead his case; but since the ailment that he long insisted on our calling *angina pectoris* was discovered to be *angina* after all, his pleadings are suspect." Quotations might be multiplied, and it is hard to know when to stop. It is enough to say that everyone who writes and everyone who cares for the beauties and the healthy development of the English language should possess a copy. The reading of it is a mental tonic and stimulant, for its closely reasoned arguments are not for the slack-minded and inattentive reader, but are worth the needful effort of concentration.

THE LAWS OF MUSCULAR MOTION.

THE Croonian Lecture of the Royal Society was delivered by Professor A. V. Hill, F.R.S., on May 20th. He began by saying that in all kinds of contractile tissues there are certain similar, or analogous, processes, so that in discussing properties of striated muscle very general phenomena were being dealt with. He went on to describe the methods available for the investigation of muscle, and discussed the recent work on chemical reactions of breakdown and recovery, and the part played by glycogen, lactic acid, and phosphate. The individual response could be split up into separate phases of contraction, relaxation, and recovery. This might be described as the "time-scale" of muscle. He gave an account of recent work on the effects of shortening or lengthening on heat production, and discussed the possibility of the utilization of the potential energy of active muscle for recovery. The question arose why, if physiological response of muscle undergoing stretch be less than that of muscle allowed to shorten, tension at any given length is so much greater during stretch than during shortening. The answer, he thought, provided an important clue to the nature of the contractile process. He concluded by considering the "viscous-elastic" phenomena in human muscular movement.

AMERICAN MEDICAL LIBRARIES.

SOME interesting particulars with regard to medical and other special libraries in the United States have been gathered by the League of Nations Committee on Intellectual Co-operation. The greatest American medical library—perhaps the greatest medical library in the world for purposes of historical research—is the library of the

Surgeon-General's Office at Washington. It contains 304,000 volumes, and, thanks to its printed catalogue, and especially to its very numerous analytical references, the library is declared by the Committee on Intellectual Co-operation to be the best existing example of the bibliographical method applied concretely to the organization of records of intellectual work on a large scale. In Washington there are three other medical libraries—one of them at the naval medical school, another a library of public health, and the third a collection of works on deafness. In New York there are ten medical libraries, three of them of the first order. In Boston six such libraries exist, including the library of the Harvard Medical School. Chicago has three medical libraries, of which the largest is the Rush library, with 25,000 volumes. These are supplemented by another Chicago institution, the John Crerar library, with about half a million books, covering, however, not only medicine, but social sciences and technology. In California there are only two medical libraries, and those not of the first order. In North America there is a Medical Library Association, which has (or had recently) a Canadian president. The committee also refers to the promotion in various fields, though rather casually, of the method of making abstracts. The most typical and extensive example of the system in America is in chemistry, and the same thing is now being carried through in the field of the biological sciences. The publication of these abstracts is promoted by the National Research Council. Of the general libraries in the States the Library of Congress, with upwards of three million volumes, and increasing at the rate of 90,000 a year, is the largest. New York public library, with 2,500,000 books, is the leading municipal library, and Harvard has the principal university library, though at one point or another it is being run close by Yale and Columbia. Harvard spends nearly £30,000 a year on books, and adds 90,000 volumes to its presses. Another line of American investigation undertaken by the League committee is the ascertainment of the number of foreign medical students at American colleges and universities. The number of such students is just under 400—a larger number than in any other faculty except engineering. The majority of these medical students come from China, Japan, the Philippines, the West Indies, and Canada. Only five students from Great Britain and one from Ireland were studying medicine in the United States when the figures were taken. Of the foreign students in dentistry, numbering in all 252, eleven came from Great Britain.

As already announced, the Norwegian Red Cross has established twenty-one medical stations in Norway for the treatment of seamen. An international agreement relating to the treatment of venereal diseases among merchant seamen has been signed by a number of countries. The Red Cross scheme is more general in scope. Under it a medical officer in every port would treat seamen for maladies falling within his province, and refer others to hospitals and specialists. The Norwegian Red Cross has invited delegations from its fellow societies and other organizations to a conference to be held in Norway from June 28th to July 5th, when visits will be paid to Oslo, Bergen, and Trondheim. The King of Norway will preside at the formal opening of the conference, and the subjects to be discussed include accidents, tuberculosis, and venereal diseases among seamen, the social conditions of seamen in foreign ports, and international co-ordination for the improvement of health conditions in the merchant service. The delegates will be given opportunities to study the Red Cross medical stations for seamen, and special demonstrations will be arranged for them. Further information may be obtained from the Norwegian Red Cross, 44, Akersgaten, Oslo.

THE THEORY OF THE CANCER VIRUS.

IS view of the widespread interest aroused by the experiments put forward last summer by Dr. Gye and Mr. Barnard in support of the view that cancer is due to the operation of a filterable and cultivable virus, the following extracts from a recent communication by Dr. James B. Murphy of the Rockefeller Institute for Medical Research, New York, may prove of interest. The article appeared in the *Journal of the American Medical Association* of April 24th, 1926 (p. 1270). It begins as follows:

"In a series of papers published between 1911 and 1916 Rous and his associates described a group of transplantable sarcomas of the chicken which could be transmitted from fowl to fowl by means of a cell free filtrate. The nature of these agents was not determined, but the natural deduction was that they belonged to the class of ultramicroscopic organisms. The main objection to this deduction was the high degree of specificity both in the animals affected and in the type of differentiation induced in the tissue. From these points it seemed more likely that the agents were closely associated with the mechanism controlling cell growth and differentiation than with an extraneous organism.

"Recently, Gye has reported experiments which he interprets as proving the presence of a living organism as the cause of malignant disease. According to him, this organism is active only in conjunction with a specific chemical factor which determines the animal species and tissue infected.

"The basis for this theory is as follows: A piece of one of the chicken sarcomas mentioned above, when placed in a special culture medium and incubated in the absence of oxygen, in the course of a few days loses its power to produce a tumour. If, however, the clear supernatant fluid from such a 'culture' is mixed with a fresh filtrate of the chicken tumour in which the tumour producing agent has been killed by chloroform, this mixture is now capable of inducing a typical malignant tumour of the chicken. Furthermore, similar 'cultures' of rat, mouse and even human neoplasms in conjunction with the chloroform killed extract of the chicken sarcoma are equally potent in inducing a malignant change in the tissues of chickens. Gye reports that the organism of the chicken tumour may be subcultured through a number of generations and still be active when injected along with the so-called specific chemical factor. It is significant that these subcultures were made with the same type of medium employed for the initial 'culture,' but with the addition of a generous supply of embryonic tissue.

"The fundamental nature of the problem involved has led us to examine the experimental proof on which this theory is based. The only source of the so-called chemical factor up to the present has been a filterable chicken tumour. The supposed organism has been obtained from a variety of neoplasms, but in Gye's original publication no mention was made of control cultures of normal tissues."

The technique employed in Dr. Murphy's experiments was similar to that used by Dr. Gye. In the first place "cultures" were made from chicken sarcoma or other material in the suitable medium—yielding the supposed cancer virus. Secondly, the chicken sarcoma was ground up with sand in Ringer's solution and filtered, the filtrate being treated with chloroform in order to kill the "virus"—the resulting fluid containing then the so-called "chemical factor."

In three series of experiments it was found that "cultures" made from mouse placenta, rat placenta, and chicken embryo acted just as well as "cultures" made from chicken or mammalian cancers when added to the chloroform-killed filtrate of the Rous sarcoma (the "chemical factor"). Several additional experiments of the same nature were performed in which tumours resulted from the treated filtrate mixed with fluid from "cultures" of embryo or placenta. In all cases the chloroformed filtrate alone proved inactive.

Dr. Murphy's article concludes as follows:

"Apparently the power to activate a chloroformed filtrate cannot be considered as proof of the action of a living organism, for cultures of embryonic tissue or placenta are just as potent in this respect as so-called cultures of malignant tissues.

"Two possibilities present themselves in explanation of the results attained. First, that the causative agent of the chicken

tumour is in the nature of an enzyme-like substance which is inactivated by chloroform and may be reactivated by a diffusible substance from malignant tumours, embryonic tissues, and placental tissues. The second possibility is that the chloroform treatment does not destroy but simply attenuates the causative agent to a point at which unaided it is too weak to induce a tumour, but in conjunction with some injurious or stimulating substance supplied by the 'culture' it becomes effective. The fact that a great excess of chloroform so completely destroys the agent that no reactivation is possible is rather in favour of the latter possibility. Further experiments are in progress to elucidate these points.

"Anaerobic 'cultures' of chick embryo and rat placenta have proved just as effective as so-called cultures of malignant tumours in activating chloroform treated filtrates of a chicken sarcoma. The necessity of assuming a cultivated living organism in the interpretation of Gye's results is eliminated."

WILLIAM OSLER.

THE MEMORIAL VOLUME.

BOTH on his seventieth birthday and after his death six months later numerous appreciations of the many-sided character of that much beloved physician William Osler were published, and last year Professor Harvey Cushing's *Life* of his teacher, friend, and hero was widely welcomed. If, as might perhaps happen, some will wonder what is the real need of the *Sir William Osler Memorial Volume* of more than six hundred pages, now brought out by the International Association of Medical Museums, the answer is given in the first sentence of the poem written by his colleague of Cambridge, the late Sir Clifford Allbutt—"I was under the belief that I knew William Osler well, intimately, almost as a brother; now I am learning how much I was mistaken. I did not know the half of him." Among the numerous movements which were initiated or furthered by Sir William Osler the International Association of Medical Museums, founded in 1911, was one of the most recent, and yet its activities are the same as those which much occupied his early days as a teacher in Montreal. It is therefore appropriate that Dr. Maude E. Abbott of McGill University, Montreal, the secretary of the association, should have gathered together a hundred and twenty appreciations and reminiscences of this much regretted master. During the six years of its preparation the work has grown under her hands and, containing as it does sidelights on every phase of Osler's life pilgrimage and activities, is a valuable sequel and supplement to Professor Harvey Cushing's fine *Life*. The contributors are, of course, mainly from America and this country, but France (Pierre Marie), Italy (Marchiafava), Germany (Sudhoff, Aschoff), and far-off China (Wu Lien-Teh (G. L. Tuck)), are also represented. Some of the articles have appeared elsewhere, such as the late Weir Mitchell's poem "Books and the Man" (1905), and some of those from Baltimore. An attractive feature is that among the 102 illustrations thirty show Osler either alone or in groups, and that many of the others show the titles of his books and papers.

In 1921 Miss M. W. Blogg, librarian of the Johns Hopkins Hospital, brought up the number of Sir William Osler's published books and articles to the large total of 1,195 titles, and now an expanded, classified, and annotated bibliography, based on Miss Blogg's, has been compiled by Drs. Abbott, Krumbhaar, Miss Blogg, Dr. Malloch, and edited by Dr. Fielding H. Garrison and Dr. H. W. Cattell. This occupies more than 130 pages and is divided chronologically into four periods—the Canadian, two American (Philadelphia, Baltimore), and the English; and by subjects into seven rubrics—natural science, pathology, clinical medicine, literary (including history, biography, and bibliography), medical education, public

¹ Bulletin No. IX of the International Association of Medical Museums and Journal of Technical Methods. *Sir William Osler Memorial Number: Appreciations and Reminiscences*. Privately issued at 836, University Street, Montreal, Canada. 1926. 64 by 94, pp xxxvii + 632; 102 illustrations. Price £2)

welfare activities, and volumes edited; they show his early interest in natural science and comparative pathology, in human pathology a little later, in clinical medicine in his prime, in literary, biographical, bibliographical, and educational matters in later life, and in public welfare to the end. In accordance with his expressed preference for bio-bibliographical presentation rather than dry lists of titles, explanatory notes and pages of important monographs and articles have been introduced. There is also a bibliography of writings about Osler occupying twenty pages and containing 460 items. The wonderful and widespread activities of Osler's fifty years (1869-1919) of professional life are only matched by the universal affection he aroused, as is proved by the contents of the appreciations from men and women in all ranks of his profession, from his colleagues, and from his innumerable students. In fact, he was even more attractive as the man than as the clinician, the teacher, or writer. Both Sir Clifford Allbutt and Professor W. H. Welch compare him with Boerhaave, and his Baltimore colleague says that there are perhaps no two physicians in history whose spirits were more akin to Osler's than Conrad Gesner and Boerhaave, and that Osler remarked to a friend about admitting Gesner to the company of Leonardo da Vinci, Paracelsus, Vesalius, Paré, Agricola, and Gilbert as the representatives of the sixteenth century in his *bibliotheca prima*, "I am not sure that this fellow should go into the *prima*; but I love him so much that I must put him there. Besides, he is the father of bibliography." In explanation, it may be mentioned that Osler's library, destined for McGill, was divided, as Dr. Mackell tells us, into *bibliotheca prima*, *secunda*, *historica*, *biographica*, *bibliographica*, *ineunabula*, and *manuscripts*.

Some of the most interesting articles are those dealing with early Canadian days; his life-long friend, F. J. Shepherd, says, and this may comfort others who were not pre-eminent as students: "Lectures did not trouble him much, and he never took elaborate notes as it was the fashion to do in those days. He took no high place in his class, but received a special prize for his graduation thesis on account of its great originality." Dr. E. J. A. Rogers of Denver, who had known him from 1866, describes his influence as a schoolboy and his life as a young professor at McGill. His relative, Mrs. H. C. Osborne, also speaks of Bill Osler, "the baby professor," in the early seventies giving away his coat to a drunken beggar, and saying on another occasion, "I whistle that I may not weep." When translated to Philadelphia in 1884 he quietly opened an "office" with the innovation of not having any office hours and seeing patients by appointment only; they were more interesting than lucrative, frequently doctors or members of their families. Dr. George Dock tells the story of the most pious and venerable member of the medical faculty who invited Osler to church, and on his guest's arrival in the pew inquired about Mrs. Osler (Osler did not marry until 1892, some years after he went to Baltimore), and then received the startling information that "Mrs. Osler is a Buddhist and would not come." Dr. Finney and Dr. Thayer, who knew "the chief" from 1889, when the Johns Hopkins Hospital opened its doors, Dr. Claribel Cone even earlier in the Baltimore period, and others, including his "first probationer," add their tributes, Thayer's poem being truly worthy of its subject. It is difficult to refrain from quoting Dr. Cone's comparison of his presentation of a case as "a masterpiece as rich in suggestion, as universal in appeal as a Giotto, a Rembrandt, or a Giorgione." Of the Oxford period Drs. A. G. Gibson and Archibald Malloch give accounts based on a most intimate experience, the first named from 1905, and the latter during the war and his last days.

Dr. Maude Abbott has carried out a great work—surely a labour of love—with complete success, for this volume may be said to fulfil the closing sentence of the veteran W. W. Keen's contribution: "In a long life I have never seen so many and such whole-hearted tributes to any other scientist. All classes of men and all countries have united to do him honour. Those who knew him best feel the loss most deeply."

HUMPHRY ROLLESTON.

Ireland.

ROCKEFELLER FOUNDATION GRANT FOR IRELAND.

THE chairman of the board of the Meath Hospital, in the course of a letter to the press, says that a statement appeared in a recent issue of the *Irish Statesman* that a quarter of a million pounds had been ear-marked by the Rockefeller Foundation Fund for Ireland, and that advantage had not been taken of the offer because medical schools and universities could not agree upon a scheme. Such an erroneous statement ought not to be allowed to pass without correction. The amount applied for was a million and a quarter pounds, to be expended in Dublin upon the erection, equipment, and partial endowment of a central hospital to take the place of five of the principal hospitals on the south side of the city, with the primary object of furthering medical education and research. Sir William Taylor, who was chairman of the Amalgamation Committee, has written to the *Irish Times* to correct an inaccurate report of what he said at the general annual meeting of Sir Patrick Dun's Hospital with reference to this scheme. The representative of the Rockefeller Trust visited the hospitals last year, and, he understood, reported favourably on the application, but the governors of the Trust had postponed its consideration on account of the present uncertainty with regard to medical education in the Irish Free State. In connexion with this subject the following facts were interesting. At the last meeting of the board of the Meath Hospital a communication was read from the medical board to the effect that since no students had applied and none was available for the position of resident medical pupil for the period April to July, 1926, other steps should be taken to carry on the work of the hospital. Further, he was informed that the number of first-year medical students in Trinity College, Dublin, for the last year (1925-26) was 36, as against 61 in the previous year, and that in the school of the Royal College of Surgeons the number was 39 as against 58, while the number of first-year medical students in Belfast had largely increased during the same period.

LOCAL AUTHORITIES BILL (IRISH FREE STATE).

The Minister for Local Government and Public Health recently introduced to the Dail a bill called the Local Authorities (Officers and Employees) Bill, 1926, described as "An Act to establish a Commission charged with the duty of selecting the persons to be appointed to situations in the employment of local authorities, and to make other provisions for ensuring the appointment of suitable persons to such situations, and also to make better provision for controlling the duties, suspension, removal, and other conditions of service of persons holding such situations." The bill provides for the establishment by the Executive Council of local appointments commissioners, not more than three in number, whose duty it shall be to recommend, with a few specified exceptions, the persons to be appointed by the Minister concerned to all offices under local authorities. Moreover, it is provided that:

"Subject to such exceptions as are or may be made by or under this Act, the Commissioners shall select every person to be recommended by them to the Minister under this Act solely by means of competitive examination conducted according to regulations made by the Commissioners;

"Every such competitive examination shall be open to all persons desiring to attend the same who possess or claim to possess the qualifications prescribed by or under this Act for the office in respect of which the examination is held and pay the fees prescribed by the Commissioners in respect of such examination."

The principal exception to the above is contained in the following provision:

"Whenever the Minister requests the Commissioners to recommend a person to appointment to an office to which this Act applies, and the Commissioners, with the concurrence of the Minister are of opinion that, having regard to the nature of the duties of that office, the knowledge and experience necessary for the efficient performance of those duties, and the qualifications prescribed under this Act for that office, the person or persons to be recommended for appointment to that office cannot be satisfactorily selected by competitive examination, the Commissioners may dispense with the competitive examination required

by this Act and may select the person or persons to be recommended by them to the Minister by such means and in such manner as they think proper."

Other clauses deal with the power of the Minister in regard to the duties, tenure, removal, etc., of officers.

Scotland.

EDINBURGH MEDICAL FACULTY BICENTENARY.

In our last issue we published particulars with regard to the ceremonies by which the bicentenary of the Faculty of Medicine of the University of Edinburgh is to be commemorated on June 10th and 11th. An official draft programme has now been issued, but the information we have already given stands good. The guests will assemble at a dinner in the upper library of the old College at 8 p.m. on Thursday, June 10th, and the graduation ceremony, at which Sir George Newman is to give an address, will take place in the M'Ewan Hall at 10.30 a.m. on the next day, Friday, June 11th. At noon there will be a service in St. Giles's Cathedral, and at 3.30 p.m. the Department of Experimental Surgery will be opened by the Secretary for Scotland at a meeting in the M'Ewan Hall. After the dinner that evening in the hall of the Royal College of Physicians of Edinburgh the Lord Provost and magistrates of the city of Edinburgh will give a reception in the Royal Botanic Garden. Among the official guests are representatives of the following universities: Oxford, Sir Archibald Garrod, F.R.S., Regius Professor of Medicine; Cambridge, Sir Humphry Rolleston, Regius Professor of Physic, and Professor J. T. Wilson, F.R.S.; Durham, Professor R. Howden, M.B., D.Sc.; Dublin, Professor T. G. Moorhead; Belfast, Dr. R. W. Livingstone, vice-chancellor; Copenhagen, Professor Johannes Fibiger, M.D., rector; Glasgow, Professor Robert Muir, F.R.S., and Professor Ralph Stockman, M.D.; St. Andrews, Professor P. T. Herring; Birmingham, Professor Edmond W. W. Carlier and Sir John Robertson, C.M.G., M.D.; Toronto, Professor Alexander Primrose, C.B. Other representatives are Professor Wilhelm Wernstedt, Medico-Chirurgical Institute, Stockholm; Sir John Rose Bradford, M.D., F.R.S., President of the Royal College of Physicians of London; Dr. R. M. Buchanan, President of the Royal Faculty of Physicians and Surgeons of Glasgow; Professor T. H. Wilson, President of the Royal College of Physicians of Ireland; Mr. R. Charles B. Maunsell, President of the Royal College of Surgeons in Ireland; Dr. Andrew Balfour, C.B., director of the London School of Hygiene and Tropical Medicine; Sir Holburt Waring, vice-president of St. Bartholomew's Hospital Medical College; Professor T. B. Johnston, M.D., dean of Guy's Hospital Medical School; and Dr. W. Aldren Turner, C.B., King's College Hospital Medical School.

GLASGOW POST-GRADUATE MEDICAL COURSES.

Under the auspices of the Glasgow Post-Graduate Medical Association arrangements have been made for a general medical and surgical course and some special clinical courses to be held during the summer months. Commencing on August 16th a whole-time course will be conducted for a month in a number of the general and special hospitals; the mornings will be devoted to general medicine, surgical diagnosis, and minor surgery, and each afternoon two special subjects will be dealt with in the special hospitals of the city. At the Royal Infirmary, Glasgow, clinical courses in surgery and dermatology will be held in June, and in anaesthetics during August, September, and October. At the Western Infirmary, Glasgow, there will be during June and July courses in clinical gynaecology; dermatology, including physiotherapy, radium, and carbonic acid snow treatment; radiology; venereal diseases; and disorders of the throat and nose. The Royal Hospital for Sick Children has arranged a course for medical and surgical diseases of children, from June till October. At the Glasgow Royal Maternity and Women's Hospital and the Royal Samaritan Hospital for Women courses in clinical obstetrics and clinical gynaecology will be conducted, the former from the middle of September to the

middle of October, and the latter during June, as well as in September and October. There will be a series of demonstrations on diseases of the ear, nose, and throat at the special hospital, beginning on September 14th. Clinical assistantships are available at several hospitals. Further information may be had from the Secretary of the Post-Graduate Medical Association, The University, Glasgow.

SCHOOL FOR INVALID CHILDREN.

The Lanarkshire Education Authority has recently established a special school for invalid children, which was formally opened on May 5th by the Rev. Alexander Andrew, vice-chairman of the authority. Sir Henry S. Keith, chairman of the authority, presided, and gave an address, in which he made reference to improvements that had taken place in recent years for children who were incapacitated in one way or another from gaining the natural advantages offered by the ordinary education. The school, which is known as the Drumpark Special School for Invalid Children, is pleasantly situated in grounds at Bargeddie, about two miles west of Coatbridge. The building is of brick, and contains fourteen classrooms, equipped with all modern appliances, and all facing towards the south. It is intended to provide for over 250 children who are physically defective and for 80 mentally defective children. The grounds surrounding the school extend to five acres, and the total cost has been approximately £25,000.

ST. ANDREWS UNIVERSITY HONORARY DEGREES.

At the installation of the Rector of the University of St. Andrews the Senatus Academicus decided to confer the honorary degree of LL.D. of the University upon several distinguished persons. The Rector chosen is Dr. Fridtjof Nansen. The following is the list of recipients of the degree: Dr. Nansen, G.C.V.O., Norway; Viscount Cecil of Chelwood; Professors Bjorn Helland-Hansen and Villhelm Bjerknes, University of Bergen; Sir T. W. Edgeworth David, University of Sydney; Professor J. Norman Collie, University College, London; Dr. Knud Rasmussen, Copenhagen; and Captain Otto Sverdrup, Norway.

England and Wales.

THE STRIKE EMERGENCY IN LONDON.

The only services of the London County Council which were discontinued in consequence of the general strike were the tramways and Woolwich ferry. The vast and complicated educational services of the Council were carried on with normal efficiency, though under difficult conditions. The school medical service was maintained at practically full strength. London ambulances had to answer a largely increased number of calls owing to the many street accidents occurring in an unexampled traffic situation. Requests were received from maternity hospitals that patients might be conveyed in these ambulances in the absence of other means of transport, but it was found impossible, owing to the other demands upon the ambulances, which are primarily for street casualties, to undertake to provide extra facilities for such cases. Special arrangements were made, however, with the British Red Cross Society and the St. John Ambulance Association to deal with maternity cases, as well as with other cases in which the borough medical officers of health were prevented by lack of transport from carrying out their usual practice.

Provisional plans for local emergency medical services were prepared by a number of Divisions of the British Medical Association, in consultation with the head office and with the police; also by the Royal Society of Medicine in the Cavendish Square area. Happily, these plans did not have to be put into operation. The Ministry of Health and the Home Office were offered the services of the British Medical Association in any capacity that might be found useful, and expressions of thanks have been received from both Departments. During the strike a large number of the Association's central staff were engaged in some form or another of voluntary part-time public service.

Hospital services in London were carried on in general

without even temporary hindrance. On inquiry at St. Thomas's we were informed that the strike had made no difference whatever with regard to supplies or services, and the same appeared to be true of other hospitals generally, with the exception of the London Hospital, which suffered a good deal from the cutting off of electric current and had to close its out-patient department for a time. The hospitals in districts, more especially east and south-east, where minor disturbances and conflicts occurred had to deal with casualties more numerous than serious. Even building and other contract work at hospitals did not cease during the emergency period.

RELATIONSHIP OF THE LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY TO THE UNIVERSITY OF LEEDS.

To any member of our profession who has lived for many years in one of the large provincial towns, and especially to anyone engaged in teaching in its medical school, the relationships which exist between the various bodies whose aim is the development and dissemination of medical knowledge cannot fail to be of interest. It is because a new bond of union has been established between the Leeds and West Riding Medico-Chirurgical Society and the University that some reference may again be made, here to the development of the society. As has been pointed out before (JOURNAL of August 20th, 1921) the society was founded on the old Leeds Medical Club, with the late Dr. Chadwick as president and the late Dr. West Symes and the late Mr. A. F. McGill as joint secretaries. From the beginning, efforts were made not only to promote the interchange of knowledge and experience by the holding of meetings, but as much as could be spared from the subscriptions was devoted to the purchase of books and periodicals. An arrangement was made with what was then the Leeds School of Medicine for the housing of these books and periodicals in the library of the school on the payment of a small annual rent, the school making itself responsible for the books being catalogued, kept in repair, and circulated. There was further this advantage to the two bodies concerned: there was a practical amalgamation of the two libraries, and though the books which constituted the joint library were indeed separately credited to the two bodies they were circulated among all those who had the right to use either library. It is of interest to recall that the library of the medical school probably had as its nucleus the small library of the General Infirmary. This arrangement was continued with the establishment of the Yorkshire College, and finally with that of the University of Leeds. It has, of course, been of the greatest advantage to both. The University has a library greatly enriched by the annual purchases of the society, and the members of the society, the University staff, and the students have all access to a much finer library than would have been possible had some such arrangement not existed. To secure the continuance of this and to lead to the further development of the library, the following agreement has been made. The society has arranged to transfer to the absolute possession of the University all its books and volumes of bound periodicals. These are to be lodged as heretofore in the library of the medical school. The society will also pay an annual sum to the University which has been fixed at a figure which satisfies each. The society will be spared the necessity of purchasing any more books and the expense of binding them, for this will be undertaken by the University, who will see to it that the library is as well supplied by periodicals in the future as in the past. When the great advantages which attach to membership of this most flourishing provincial society are considered one wonders that the membership is not greater than it actually is. The subscription is one guinea for Leeds members and half a guinea for those beyond a certain radius. The privileges of membership are the full use of a growing and valuable library, with all the freedom of access which is enjoyed by the members of the University and with the power to take out books, and free access to the reading room with its large collection of periodicals. The library is kept open for the convenience of members on those evenings when meetings are held.

Then the other advantages of membership are, of course, those which arise from the ordinary activities of the society. About a dozen meetings are held during the months from October to May, and these include usually two special clinical evenings and two pathological evenings which are always attractive. The general meetings and the special clinical meetings of the society are held at the General Infirmary, which adjoins the medical school of the University, and the society has, through the heads of the various departments of the University, every facility which can arise from the free use of lanterns, apparatus, and specimens. There is no better way, and certainly none more useful to the individual, for former students of the school—whether they be graduates of the University or not—to keep up their connexion with the scene of their studies than by joining this society and by assiduously attending its meetings.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

The annual meeting of the King Edward's Hospital Fund for London to receive the accounts and report for 1925 was held at St. James's Palace on May 14th, the President, H.R.H. the Prince of Wales, taking the chair. Lord Revelstoke, the treasurer, reported that the total of the ordinary distribution of £245,000 during the year marked a record, and had been met entirely out of income; there was a good prospect of maintaining this level in future years if the receipts from legacies, subscriptions, and donations remained at about the present figure. The British Charities Association had increased its grant from £15,000 to £20,000, Lady Strathcona had contributed £5,000, and two anonymous gifts of £6,000 and £2,250 had come in; an additional anonymous donation of £7,000 received more recently would be of great assistance in the distribution of the present year. The Earl of Donoughmore, chairman of the Management Committee, moving the adoption of the annual report for 1925 of the General Council, called attention to the conferences held between the King's Fund and various associations with reference to the provision of pensions for hospital officers and nurses. We gave some details of the draft scheme on December 19th last (p. 1195). This scheme, besides enabling members of hospital staffs to make adequate provision for old age, would also benefit the hospitals, since it would enable them to stabilize their finances by providing for future liabilities on an instalment plan, and it would render the hospital service more attractive to the officers and nurses. It was suggested that the assistance offered by the King's Fund might be a maximum sum for seven years of £20,000 a year, or 25 per cent. of the expenditure by the hospitals on the approved scheme, whichever was the smaller. This amount should be provided as far as possible by contributions received in response to a special appeal, and be increased if sufficient funds were obtained in this way. Lord Burnham, chairman of the Propaganda Committee, referred to the very valuable support received from the British Broadcasting Company, and Mr. L. L. Cohen, chairman of the Hospital Economy Committee, presented a report on the new edition of *The Revised Uniform System of Hospital Accounts*, to which we referred in our last issue (p. 843). The Prince of Wales spoke of the loss to the Fund caused by the death of Lord Stuart of Wortley, one of its honorary secretaries since its inception twenty-nine years ago. He referred at some length to the report of the Management Committee on the subject of pensions for hospital officers and nurses, indicating how hospital efficiency was impaired through lack of an adequate pension scheme. There seemed to be a widespread agreement that the advantages justified the additional expenditure involved, and it was to be hoped that the scheme would commend itself to the supporters of the hospitals and of the King's Fund. It would enable hospitals to provide in a businesslike way for an essential part of their expenditure, and it would remove a heavy burden of apprehension from the members of the nursing profession. His Royal Highness mentioned that the hospitals would have suffered financially owing to the recent national emergency, but he trusted there would be a general determination to ensure that the loss should be only temporary.

YORK FEVER HOSPITAL.

The Health Committee of the York City Council has recommended extensions and improvements at the Fever Hospital and Fairfield Sanatorium. The York Division of the British Medical Association, which had previously sent a deputation to the Health Committee of the Corporation to call attention to the inadequacy of hospital accommodation in York for epidemic diseases, appointed four of its members (Dr. J. G. Craig, chairman of the Division, Dr. W. A. Evelyn, Dr. H. E. K. Reynolds, and Dr. J. C. Lyth) to attend a meeting of the York City Council on May 3rd. Dr. Reynolds indicated the urgent necessity for the provision of accommodation for severe cases of non-notifiable infectious disease. There was, he said, no provision in York for isolating a bad case of measles, and there was accommodation for only about sixteen cases of scarlet fever and sixteen of diphtheria. After discussion, an outlay of approximately £30,000 was approved for the necessary extensions; this will involve an increased rate of 1½d.

THE BETHLEM HOSPITAL SITE.

At the meeting of the London County Council on May 18th approval was given to the Bethlem Hospital Bill (as now proposed to be amended), which provides *inter alia* for the confirmation of an agreement between the governors of the hospital and Viscount Rothermere for the sale and purchase of the site of the hospital and grounds, and for the vesting of the whole of the site, or in certain circumstances a part only, in the London County Council as an open space. It was stated that, in the event of the whole site being vested in the council as an open space, the expenditure that would devolve upon the council was estimated at £16,550 for the lay-out and incidentals, and £3,000 a year in respect of subsequent maintenance.

LONDON COUNTY COUNCIL PUBLIC HEALTH ESTIMATES.

The expenditure for the financial year 1926-27 for purposes under the administration of the Public Health Committee of the London County Council is estimated at £456,600. This includes a sum of £116,530 for the residential treatment of tuberculosis (a decrease of £4,110 on the previous year), £18,600 on dispensary treatment (an increase of £1,100), £97,305 on the diagnosis and treatment of venereal diseases (an increase of £1,300), and £136,000 on grants to boards of guardians in respect of Poor Law medical expenses (an increase of £11,000). The Council, however, has no control over the amounts of the last named grants, which depend upon certificates issued by the Ministry of Health. These sums do not entirely cover the expenditure of the Council on public health, certain further provisions being voted under other committees, especially in regard to lying-in homes and to infant life protection.

Correspondence.

CERVICAL CANCER AND VENEREAL DISEASE.

SIR,—In the report¹ of the meeting of the North of England Obstetrical and Gynaecological Society held on March 19th in Liverpool it is stated that Miss Ruth Nicholson showed three cases of carcinoma of the cervix in women undergoing treatment for syphilis and gonorrhoea, and after mentioning three references she concluded by stating that "These were the only cases and references she had found recorded."

May I be permitted to direct attention to what I have stated in my book on *Cancer of the Womb*, concerning the etiology of cervical cancer? Discussing the relationship of venereal disease to cancer, on page 17 it is written:

"Syphilis is held by some to play an important part, but there is no well authenticated proof that it does so in the uterus, as cancer does not appear to be more common in those who have contracted syphilis. There is more evidence in favour of gonorrhoea as a predisposing cause of cervical cancer, for by the produc-

tion of chronic cervical gleet it favours those cell changes which lead to cancerous formation. I have met with several cases in which the relationship was clinically established."

I have seen and described cases of cervical cancer in syphilitic women where the manifestations of syphilis were in the tertiary stage, but whether or not the primary sore was situated in the cervix could not be determined. I also pointed out (*ibid.*, p. 52) that a primary cervical sore is not rare. This statement was challenged by some of my critics, but Fournier's statistics show that of 249 genital chancre in the female 13 were cervical. I have not yet seen a cervical gumma, but a photograph (*ibid.*, Plate xiii) represents a cervical cancer removed from a woman who had tertiary syphilis. Whether her syphilis predisposed to the development of cancer could not be determined.

It is unfortunate that the venereal clinics for women have been separated from those devoted to gynaecology, for the importance of venereal disease as an etiological factor in the diseases of women is apt to be overlooked or misinterpreted. The relationship of venereal disease to cervical cancer is much more likely to be determined by a study of the women seeking relief for cancer in the gynaecological clinic than by a study of those seeking relief for venereal disease in whom cancer is accidentally discovered.—I am, etc.,

"RECOVERY AFTER MASSAGE OF THE HEART"—AND, OR, OTHER MEANS?

SIR,—Mr. Girling Ball records an exceedingly interesting case of restoration of the heart's action after stoppage during the performance of a major surgical operation (*BRITISH MEDICAL JOURNAL*, April 24th, 1926, p. 732): "the patient suddenly stopped breathing and his heart ceased to beat." The measures adopted were as follows: (1) gentle massage of the heart through the diaphragm at the rate of 60 a minute, while (2) artificial respiration was maintained; (3) an injection of 10 minims of a 1 in 1,000 solution of adrenaline into the heart muscle through the chest wall. After an interval of three minutes heart contractions began, and gradually a normal but somewhat accelerated rhythm was established. The breathing started shortly after the heart began to beat. The surgical operation was then restarted and completed within forty minutes. The result was a complete success.

The object of my writing is to ask why this admirable achievement is attributed to heart massage and to this alone, and next to draw the attention of those, who are interested, to a paper which appeared in the *Lancet* of March 24th, 1923, in which the whole problem of resuscitation after systemic death—that is, cessation of heart and respiration—is dealt with at length; Dr. Carl Bodon of Budapest is the author. He discusses the records of ninety cases collected by him in which a variety of medicaments were employed by intracardiac injection—including camphor, caffeine, the digitalis glucosides, adrenaline, pituitrin, and strychnine. Need it be said that the successes of such treatment in these desperate cases (especially in cases of sudden death from medical causes) are minimal, if we look for permanent results, but his own striking case (medical) of complete cure, and a sufficiency of temporary rallyings, will be found to encourage us to adopt intracardiac injection in increasing measure in such cases. Of the drugs above mentioned adrenaline has given the best results in doses of 1 c.cm. of 1 in 1,000; this was the reagent Dr. Bodon used. A long needle should be used (8 cm., just over 3 inches), and the site of election for puncture is the fourth left intercostal space, on the upper edge of the fifth rib close to the sternal border. The paper must be consulted for careful and detailed directions. It is held that intraventricular injection is to be aimed at, and not injection into the walls of the heart. In Dr. Bodon's case the heart beat appeared within a few seconds.

On the evidence before us we cannot exclude adrenaline as at any rate sharing in the triumph; may it not have been the chief cause? At what relative stage was it administered?—I am, etc.,

London, W.1, May 12th.

¹ *BRITISH MEDICAL JOURNAL*, May 1st, 1926, p. 755.

MENTAL IRRITABILITY AND BREAKDOWN IN THE TROPICS.

SIR,—The letter of the Bishop of Singapore on the subject of mental irritability and breakdown in the tropics, in your issue of March 13th, has interested me very much, and in compliance with his request for the experience of others living under similar conditions in the tropics I am writing to give him the results of my personal experience and observation. I regret to say that I am one of the victims of this unfortunate and unpleasant trait, inasmuch as I am a medical officer in the local medical service and in the enjoyment of private practice, and to anyone similarly engaged in a tropical colony it is a great handicap to be at all liable to outbursts of temper. In my own case I can only attribute this irritability in my disposition to working under mental and physical high pressure for many years at a stretch, in a position of great responsibility during nine years, with a period of furlough in a neighbouring colony of six weeks' duration. This colony (British Guiana) is situated just a few degrees above the equator, and its coastlands are below sea-level. The only means of obtaining a change of altitude is to go for a period either to the neighbouring colony of Barbados or else to Great Britain or Canada; this is so much recognized by the Government of this colony that assisted passages are granted to public officers to enable them to proceed on furlough to northern climes.

The late Colonial Secretary of this colony and now Governor of Hong-Kong (Sir Cecil Clementi), as the result of his travels in the interior of this colony, was the first to point out the advisability of establishing hill stations in the interior of this colony to enable public officers and other residents to spend short but frequent periods of furlough for the benefit of their health. Nothing, however, has been done in this matter, due chiefly to the expense of travelling and the lack of proper quarters for residential purposes. The only provision in this direction is the trip to the Kaietur Falls, which can be done under tolerable conditions of travel in about four or six weeks (return passage); but its considerable monetary outlay is beyond the reach of the ordinary colonist.

In short, the great cause of mental irritability is the same daily monotonous grind, carried on under conditions of great physical exhaustion, without the possibility of a change of surroundings, even of a few days' duration, from time to time.—I am, etc.,

Q. B. DE FREITAS, M.R.C.S., L.R.C.P.,

New Amsterdam, April 15th.

British Guiana Medical Service.

SIR,—With regard to the recent correspondence on irritability in the tropics perhaps one more observation may be worth consideration.

A good deal of notice is taken of heat and light chiefly because they are obvious, but there is another factor—namely, barometric pressure—which is not often taken into account. I can only speak of this part of the world, but here the barometer varies very little from 29 in. the whole year round. I believe that one of the things the European body misses in many parts of the tropics is the constant, steady, and comparatively wide variation which is always occurring over Great Britain and a large part of Europe.—I am, etc.,

M. JACKSON, W.A.M.S.

Colonial Hospital, Sierra Leone, April 15th.

SIR,—In reply to the question of the Bishop of Singapore, in the JOURNAL of March 13th, allow me, please, to say that I think the causes are: (1) The exhaustion of the reserves of the nervous system by the excessive and unaccustomed stimuli of the tropics—light, heat, flies, the strange languages and customs, the appalling moral atmosphere in view of what one is accustomed to; (2) the inability of some white folk to take things easy and not worry; (3) the ridiculous customs as regards food, dress, and hours of work. Fancy wearing top hats and frock coats, and so forth, to functions in the tropics, and working on steadily through the hottest hours of the day.

May I add one word of warning? No one who has

suffered in the late war from shell shock or any type of nervous breakdown ought ever to come to the tropics. It is absolutely asking for trouble.

There are other factors, too, but your other correspondents have touched on these. Dark-coloured glasses are very helpful.—I am, etc.,

L. D. PARSONS,
Superintendent, Government
Lunatic Asylum.

Angoda, Ceylon, April 20th.

Obituary.

STEPHEN PAGET, M.A., F.R.C.S.,

Consulting Aural Surgeon, Middlesex Hospital; Vice-Chairman,
Research Defence Society.

We deeply regret to have to record the death, on May 8th, of Mr. Stephen Paget, who was for many years well known and liked in London and greatly respected throughout the profession for his courageous defence of experimental medicine.

He was born in 1855, the fourth son of Sir James Paget, to whom he bore a striking physical resemblance and whose literary abilities he inherited. He was at Shrewsbury School and Christ Church, and throughout his life bore the impress of Oxford. Another impress he bore was that of his father's home, which sheltered a large, united, and able family. James Paget in his prime was in the habit of working with his family about him, helped and not hindered by the music of his wife, who was an accomplished musician. Though he laboured far into the night, helped by a secretary—a place for some time held by Stephen Paget—at the preparation of lectures and other writings and in completing his correspondence each evening, he was a friend of most of the great men in literature and science during the later part of the Victorian era, when some very great men were working and writing. Among them were Tennyson, Browning, George Eliot, Lowell, W. E. Gladstone, Pusey, Ruskin, Tyndall, Huxley, Matthew Arnold, Virchow, Pasteur, and Darwin; among his close friends in the medical profession were Bowman, Sharpey, Sir John Simon, Sir Andrew Clark, and Sir Thomas Smith. To know such men in his father's house was a privilege which the son thoroughly appreciated and enjoyed to the full.

Stephen Paget received his medical education at St. Bartholomew's Hospital, to which his father was at that time consulting surgeon, and after serving as house-surgeon there went out into the world. His first independent appointment was that of surgeon to the Metropolitan Hospital; afterwards he was surgeon to the West London Hospital, and in 1897 was appointed aural surgeon to the Middlesex Hospital. At the outbreak of the great war he lectured to soldiers for the War Office all over the country, on hygiene, typhoid inoculation, and kindred subjects; the strain was too great for a constitution never very robust, and his health entirely broke down. In 1916 he partially recovered and went to Petrograd in charge of the Anglo-Russian Hospital for the winter of 1916-17. He had some years previously given up practice as a consultant, and in 1918 finally retired and went to live at Limpsfield, Surrey, devoting himself to writing and to the management of the Research Defence Society, which he was mainly instrumental in founding and of which he was honorary secretary.

On the first page of the first minute-book of the Research Defence Society the following entry occurs: "A meeting of 'Professor Starling's Committee' was held at 70, Harley Street, at 5 o'clock, on Monday, Jan. 27th, 1908. Present, Prof. Cushman in the chair, Sir Victor Horsley, Dr. Bcevor, Dr. Head, Dr. Leonard Hill, and Mr. Paget. Also, Lord Justice Fletcher Moulton and the Hon. Sydney Holland [now Lord Knutsford]. At the proposal of the Hon. Sydney Holland, all present, excepting Lord Justice Fletcher Moulton, agreed to form a Society, to be called The Research Defence Society. Mr. Paget was appointed Hon. Secretary."

Thus began perhaps the most vigorous chapter in the life of Stephen Paget: it was through his initiative that the Research Defence Society was born; it was through his boundless energy in its service that it grew, and that now

it can justly claim to have played an important part in bringing the general public to realize the importance of research in medicine to the community, individually and collectively. Mr. Paget has described the birth of the society as follows:

"Professor Starling's Committee had been careful to put things fully and plainly to the Commission (the Royal Commission on Vivisection). The opportunity must not be lost; the general public must be taught the rights of the matter. Then, in January, 1908, when all the evidence had been given and published, and Professor Starling's Committee had served its purpose, it seemed a pity to break such good machinery, and out of that committee was formed the Research Defence Society. . . . People were sick of antivivisection: the Brown Dog case had made them wonder at the ways of its followers. People wanted and welcomed a fighting society which would tell them the truth about experiments on animals made in this country under the conditions of the Act."

This "fighting society" found in Paget its ideal champion and leader. To him, imbued by nature with love and charity for all men, disease and pain were evils, works of the devil, to be combated with all the means at our disposal. Evil also must be any movement or action which tended to perpetuate the ignorance out of which these misfortunes arise. It is not surprising, therefore, that the antivivisection agitation, with its methods of lying and calumny, aroused in Paget a righteous indignation and a burning desire to do battle for the truth and to further the divine work of research. How well he carried out his self-imposed task can be read in the records of the Research Defence Society.

He wrote innumerable pamphlets, lectured, debated, organized meetings, edited the journal *The Fight Against Disease*, and was indefatigable in his efforts to contradict the false impressions ladled out to the public by the antivivisection societies. He realized that, left unchallenged, the so-called facts put in print by his opponents might do incalculable harm to the progress of medical science, and laboured with a religious zeal in the cause he championed. Even during the last years of his life, when physically weakened by illness, he retained his vigour for any cause associated with the objects for which the society was founded. He had an encyclopaedic knowledge of all persons, subjects, and tactics connected with the opposition, and had carefully prepared notes for the continuation of his work should he be unable to carry on.

Stephen Paget was the "vital spirit" of the society from the very beginning, and his personality permeated all its literature. All members of the medical profession, and research workers in particular, may well feel proud of and indebted to this famous author and surgeon, who devoted so many years of his life to overthrowing the obstacles deliberately placed in the way of medical progress.

Paget's reputation as a writer was established by the publication in 1901 of the *Memoirs and Letters of Sir James Paget*. The volume consisted of two parts; the first was an autobiography bringing the story, with notes by the editor, down to 1865; it included references to the succession of illnesses which caused him to resign from the office of surgeon at St. Bartholomew's in 1871. The second part was made up mainly of his letters, with notes by the editor, to which were added several chapters on his later years. In the following year Stephen Paget edited the volume of his father's *Selected Essays and Addresses*. In 1912, in co-operation with the Rev. J. M. C. Crum, he wrote the life of his brother, Francis Paget, Bishop of Oxford. After his retirement he undertook the biography of Sir Victor Horsley, published in 1919, and in 1921 the life of Canon Scott Holland, his father's friend and his own. While still in practice he had written a book (1896) on the surgery of the chest. In 1897 he contributed to a series of medical biographies, then being issued, a life of John Hunter, and in the same year issued an independent volume on *Ambroise Paré and his Times*. In 1908 appeared *Confessio Medici*, a book of essays which was found very helpful by many members of his profession. He early showed an interest in what has been called the antivivisection controversy by publishing a book entitled *Experiments on Animals*, a third edition of which appeared in 1906. In 1912 he published another volume on the same subject with the title *For and Against Experiments on Animals*, and followed this up in 1914 by

Pasteur and After Pasteur. He was in great request as a writer in the periodical press, and was for many years a not infrequent contributor to our columns. He was a member of the British Medical Association, and at the Annual Meeting in London in 1910 was vice-president of the Section of Laryngology. He had constant ill health for the last ten years of his life, but had the companionship and devoted ministrations of his wife, a daughter of Dr. Edward Burd of Shrewsbury, who had been one of his father's pupils. During these years his indomitable courage kept him always busy till a second cerebral haemorrhage brought him the rest he had long wished for.

S. G. CAMPBELL, C.M.G., M.D.,
Durban.

We regret to have to record the death, on March 12th, of Dr. S. G. Campbell, who was not only one of the leading medical practitioners in Natal, but also one of its chief citizens. He was a son of William Campbell, who came from Scotland in 1815 and was one of the pioneers of the sugar industry, owned one of the first railways in South Africa, and built wharves. He was a staunch advocate of technical education, and founded the first technical school—a point of considerable interest, for his son, the subject of this notice, was one of the founders of the Natal Technical College, which has been described as the best monument to his memory. He devoted a great deal of time to its development, and was rewarded by seeing the institution expand so rapidly that in 1909, when he was its president, it became necessary to erect a new and larger building, which was completed in 1912. Dr. Campbell continued his efforts until it was completely equipped and the prospects were good for a further extension suitable to the needs of a university college. It was in recognition of his work for education that the honour of C.M.G. was conferred upon him two years ago.

Dr. Campbell received his early education in the colony, but afterwards went to Edinburgh, where he graduated M.D., and practised for a short time in Glasgow. Shortly after his marriage there he returned to Natal, and, after working for some years in association with Dr. A. McKenzie, entered on independent practice. His medical work was interrupted, or perhaps it should more correctly be said transferred to another sphere, during the Boer war. He was in Ladysmith during the siege as surgeon to the local forces; later on he was the first commanding officer of the Mounted Infantry Company of the Durban Light Infantry. Dr. Campbell was an enthusiastic Volunteer, and when the native rebellion broke out in 1906 he took the field in his capacity as major of the D.L.I., and while in command of a convoy escorted by a composite force of about 150 men successfully repelled a fierce attack by the native impis. During the great war Dr. Campbell served again in the care and relief of the sick and wounded. He was remarkably successful as a medical practitioner, but in addition to the very active interest he took in all educational questions he was ever ready to assist in movements for the betterment of the public health; after his return to Durban from Edinburgh he was for a time medical officer of the Durban Corporation, and later in life gave his aid to such organizations as the Child Welfare Society and the Red Cross.

When Dr. J. A. Macdonald, at the request of the Council of the British Medical Association (of which he had until the previous year been chairman), visited South Africa in the autumn of 1921 he was everywhere very cordially received, but nowhere more cordially than in Natal; he was for ten days the guest in Durban of Dr. Campbell, then president of the Natal Coastal Branch of the British Medical Association. The primary object of Dr. Macdonald's visit was to attend the medical congress in Durban, of which Dr. Campbell was president. Dr. Macdonald had a most kind and flattering reception from the congress, and Dr. Campbell's hospitality and readiness to help know no bounds. Dr. Campbell was equally hospitable and equally helpful to the Medical Secretary, Dr. Alfred Cox, during his recent visit to South Africa. His hospitality, Dr. Cox tells us, was famous even in a city where hospitality is one of the prime virtues regularly

practised. He took a deep interest in Dr. Cox's mission, and his advice with regard to the reorganization of the Natal Coastal Branch was of very great value. Dr. Campbell (Dr. Cox adds) was a man of great wit and charm, kept open house, and a visitor to it was always sure of meeting interesting people in a delightful atmosphere.

Dr. Campbell is survived by his widow and six children, a daughter and five sons, one of whom was associated with him in practice. With them great sympathy is felt, and the funeral was attended by a very large assembly, including representatives of the many local institutions with which Dr. Campbell had been associated, the Principal and a representative body of the staff and students of the Technical College, the town clerk and town treasurer, and the medical officer of health.

We may conclude this brief notice of his life's work by quoting the following sentences from one of the many tributes to his memory published by the local press:

"His tastes, like his sympathies, were catholic. He loved several kinds of sport; he was deeply concerned in politics, both municipal and national; he had all a Scotsman's veneration and affection for the 'land of brown heath and shaggy wood,' and he had also that saving grace of humour in the fullest plenitude. As a speaker on almost any subject he was entertaining as well as instructive, and he had always a high purpose in view."

Mr. CHARLES ERNEST PRONGER, who died on April 2nd at his residence in Harrogate, received his medical education at St. Thomas's Hospital, where he obtained the L.R.C.P. diploma in 1876 and the F.R.C.S. in 1891. He was for some time assistant demonstrator of anatomy at St. Thomas's. After a period of general practice in Barnstaple, during which he held the post of surgeon to the Barnstaple and North Devon Infirmary and consulting surgeon to the Barnstaple and North Devon Dispensary, Mr. Pronger removed to Harrogate in 1892, where he built up an extensive consulting practice in ophthalmic surgery. He was consulting ophthalmic surgeon to the Harrogate Infirmary, the Yorkshire Home for Chronic and Incurable Diseases, and the Northern Police Orphanage. He founded the eye department at the Harrogate Infirmary, and collected the necessary funds. Mr. Pronger made a special study of refractive errors, and was one of the first in this country to emphasize the importance of correcting minor irregularities. He pointed out that the grosser errors did not trouble the patient so much as the minor degrees, since in the latter case the eyes were constantly being strained in the endeavour to overcome the fault, an effort which was not made when the refractive error was greater. He was an enthusiast in this particular field, and won wide popularity by his success in relieving migraine, headaches, neurasthenia, and mental depression due to ophthalmic causes. He was the author of two monographs—one entitled *Slight Errors of Refraction and their Influence on the Nervous System*, and the other *Insomnia and Suicide*. He also published a paper on vertigo and its relation to errors of refraction. He took a keen interest in golf, and was at one time captain of the Harrogate Golf Club. He leaves a widow, but no children.

Dr. WILLIAM DODGSON BARROW, who died on April 10th, at the age of 55, in the Royal Lancaster Infirmary, was a member of a well known family which for more than a century has been prominently associated with the public life of Lancaster. He received his medical education in Edinburgh, where he graduated M.B., C.M. in 1893. In the same year he obtained the diplomas M.R.C.S. Eng. and L.R.C.P. Lond., and in 1897 became a Fellow of the Royal College of Surgeons of Edinburgh. His early appointments included those of assistant demonstrator of anatomy at Edinburgh, house-surgeon to the Borough Hospital, Birkenhead, and ambulance surgeon to the Royal Southern Hospital, Liverpool. He then returned to Lancaster, and was house-surgeon at the Royal Lancaster Infirmary 1898-99, and additional visiting medical officer from 1900. In 1903 he became honorary anaesthetist, and in 1909 an honorary medical officer to the Infirmary. During the war he was a member of the medical

board, and chairman of the finance committee of the Prisoners of War Care Committee. He was elected to the Lancaster Town Council in 1922, and served on various committees. He was for many years a member of the British Medical Association, and was honorary treasurer of the North Lancashire and South Westmorland Branch from 1904 to the time of his death. He was also a member of the Executive Committee of the Lancaster Division of this Branch from 1913 to 1926. He took an active interest in sport, and associated himself with the local Rugby football club, the cricket, bowling, and tennis club, and the golf club.

Dr. ARTHUR BENJAMIN WINDER died at St. Anne's, Lancashire, on April 22nd, aged 68. He was educated at the University of Edinburgh, where he graduated M.B., C.M., in 1884, and proceeded M.D. in 1892. After serving as assistant to the ear and throat departments of the Edinburgh Royal Infirmary and as medical officer of health for Thurstonland, Yorks, he commenced practice in Blackpool about thirty-five years ago, and was very successful. At the outbreak of the war he received a commission in the R.A.M.C., and was instrumental in establishing the Station Road Red Cross Hospital. He was subsequently promoted to major and appointed medical officer in charge of the x-ray and electrical department of the King's Lancashire Convalescent Centre, Blackpool. Dr. Winder, who removed to St. Anne's about a year ago, was created a justice of the peace in October, 1922. He was a member of the Blackpool Division, and took great interest in golf, having been captain of the Blackpool Golf Club on two occasions. He is survived by his widow.

Dr. EDWARD GURDON FREDERICK, who died on April 27th, after a long illness, received his medical education at King's College Hospital, taking the diplomas M.R.C.S. Eng., L.R.C.P. Lond. in 1896. Dr. Harold Beadles (Romford) writes: I have known Dr. Frederick during practically the whole of his professional career. For the last three years he practised at Seven Kings, but previously he had spent over twenty years in the dock district of West Ham. Those who have lived there will know of the hard work that falls to the lot of the professional man in such a district. Dr. Frederick had, nevertheless, always found time to devote to the interests of his fellow practitioners, and had been an active member of the Stratford Division of the British Medical Association since its inception. He was a member of the executive committee almost from the start, and chairman during the year 1921-22. He was one of the representatives of the Division at the Annual Meeting at Bath last year, and was diligent in his attendance at meetings of the Metropolitan Counties Branch Council.

Dr. ARCHIBALD BURNS GEMMEL died suddenly on April 28th. His health had been indifferent for some months past, and there is little doubt that the pressure of work during the strenuous years of the late war had left its mark. He was born in Dunoon, Argyllshire, sixty-four years ago, studied medicine in Glasgow, obtained the diplomas of L.R.C.P. Ed. and L.R.F.P.S. Glasg. in 1883, and became M.R.C.S. Eng. in 1884. After holding residential appointments in Glasgow and in Rangoon, Dr. Gemmel settled in general practice in Liverpool. He was a licen Volunteer, and became surgeon to one of the local Volunteer regiments of those days; which, six years before the war, became the Territorial Force of the city. At the outbreak of the war he became officer commanding the 1st Western General Hospital, and held the rank of lieutenant-colonel during the war. Under him the Infectious Diseases Hospital at Fazakerley formed the central hospital of the Western Command. Some thirty-two Liverpool hospital physicians and surgeons, as officers *à la suite*, were under the military authority of Dr. Burns Gemmel. Such a post demanded great tact and judgement, especially towards men of high standing in their profession and quite unversed in military routine. Friction at times was inevitable, but

on the whole the machine worked satisfactorily. Later on Dr. Burns Gemmel saw service in Boulogne and Marseilles, being in charge of similar hospitals. At the end of the war he was made C.B.E., and resumed private practice. Dr. Burns Gemmel leaves a widow, a daughter, and a son, to whom we desire to express our regret in their bereavement.

The Hon. Sir H. A. A. NICHOLLS, formerly principal medical officer of Dominica, West Indies, and well known for his work on tropical diseases, has recently died at the age of 74.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons rose on May 20th until June 1st. The chief business of the week has been the second reading of the Finance Bill; but the recent general strike has reduced parliamentary activities. Few questions were asked, and the meeting of the Parliamentary Medical Committee projected for May 19th was postponed. The Select Committee on Nursing Homes sat that day to take evidence from the chief medical officer of the London County Council.

Recreation Grounds in Urban Areas.

On April 28th the Hon. E. Cadogan opened a debate on the provision of recreation facilities in urban areas. In moving that the Government should insist on adequate provision of these facilities in town-planning schemes, and if necessary should confer greater powers, he said that in the report of the Royal Commission on National Health Insurance reference was made to the fact that the British Medical Association in its evidence doubted whether under a limited expenditure the best results in improvement in public health could be expected on the lines of National Health Insurance. The Association had suggested that, with an equivalent expenditure, better results might be expected from the application of the money for "proper housing and town planning, with due provision for recreation." The Minister of Health, said Mr. Cadogan, could not afford to ignore that testimony. By support and encouragement of athletics in industrial areas of great cities Parliament could not only improve the breed of mankind, but also its "moral qualities." He urged that any application for a grant from the Unemployment Grants Committee which had recreation grounds for its object should receive favourable consideration. He regretted that the Office of Works had incurred the charge of not being sympathetic towards the recreative needs of the public.

Mr. Campbell said that in the three years' plan of the London County Council Education Committee which was now running the Committee had specially arranged to have sites for elementary schools with ample playing ground. Of every £100 spent by the county on education only £2 4s. went on the school medical service. Money spent on schemes for recreation and playing fields would not in the long run be expensive, because they would save on doctors' bills. Mr. Morgan Jones said that in the years 1923 to 1925 the lowest figure for the loss of work through ill health in any one year was not below 70,000,000 weeks. Lady Astor said there was no more pitiable sight than the arrest of children for playing in the streets. They must provide healthy recreation for girls as well as for boys.

Sir Kingsley Wood pointed out that the Public Health Act, 1925, gave more power to urban and rural authorities, and also to county councils, to acquire, lay out, and maintain land for the purpose of games and recreation. During 1924-25 the Ministry of Health sanctioned an expenditure of nearly £1,250,000 on the provision of open spaces. The Minister was considering whether procedure for the acquisition of land for such purposes could not be made more expeditious. In many localities where people were living in disgraceful conditions housing must, however, come first. He was sure the House would agree with him in thanking Lord Rothermere for the gift of the site of the Royal Bethlem Hospital to be a playground and a park for Southwark. Mr. Cecil Wilson said that unless the Ministry of Health dealt with the smoke nuisance the value of some of the open spaces would be destroyed. They had an area in Sheffield where there was not a tree within a mile, because trees could not grow there as the result of the effect of the smoke upon them. Mr. Hopkinson asked whether this generation was town planning for a greatly increased population, or, as he hoped, for a vastly decreased population. The House agreed with the motion calling for adequate provision in town-planning schemes for the reservation of open spaces.

Coroners Bill.—In the House of Commons, on May 12th, the Coroners (Amendment) Bill was read the second time.

Midwives and Maternity Homes Bill.—The Midwives and Maternity Homes Bill was given a second reading in the House of Lords on May 17th. The Marquess of Salisbury, Lord Privy Seal, explained that the measure amended the Midwives Acts of 1902 and 1918, and provided for the registration and inspection of maternity homes. It also enacted that no person, except in

a case of sudden or urgent necessity, should attend a woman in childbirth except under the direction and personal supervision of a duly qualified medical practitioner. The Archbishop of Canterbury said that the bill exempted from registration premises for the conduct of which a duly qualified medical practitioner resident therein was responsible. This, he suggested, might be an undesirable loophole. Lord Knutsford said that he did not see why hospitals should be excluded from inspection, and Lord Salisbury promised to give consideration to these points before the Committee stage.

Treatment of Tuberculosis.—On May 11th Sir J. Gilmour told Dr. Shiels that he had no exact information as to the extent to which pneumothorax treatment was practised in connexion with tuberculosis schemes. He was advised that medical opinion was not unanimous as to the value of this particular form of treatment, and its use, generally and in individual cases, must necessarily be left to the discretion of the responsible medical officers of the local authorities. X-ray installations for diagnostic purposes had been provided, or were in course of being provided, in fifteen institutions belonging to local authorities or combinations of local authorities. Local authorities which had not provided facilities of their own made arrangements with the authorities owning these institutions or with voluntary hospitals or other bodies which had the necessary facilities. On May 11th Sir J. Gilmour told Dr. Shiels that facilities for the treatment of tuberculosis by ultra-violet radiation (light treatment) had been provided, or were in course of being provided, by each of the four large cities in Scotland, the Middle Ward District Committee of Lanarkshire, the burghs of Greenock, Paisley, Motherwell and Wishaw, Coatbridge, Falkirk, Kirkcaldy, the county council of Ross and Cromarty, and the following combinations of local authorities: the Fife and Kinross Joint Sanatorium Board, the South-Eastern Counties Joint Sanatorium Board, and the Dumfries and Galloway Joint Sanatorium Board. The facilities so provided by local authorities were, by arrangement, in some instances available for neighbouring areas, and the facilities provided at certain voluntary institutions were also available to local authorities. The nine first mentioned local authorities and the burgh of Kilmarnock also provided, or were in course of providing, light treatment in connexion with their schemes of maternity service and child welfare. The Minister of Health, replying, on May 12th, to Dr. Shiels, said that in England, out of the 152 local authorities concerned, at least 115, according to information in his department, made arrangements for x-ray examinations, and at least 59 had arrangements available for pneumothorax treatment. It was possible that such arrangements existed in some of the other areas. In Wales, arrangements for both purposes had been made by the Welsh National Medical Association, with which all the local authorities in Wales contracted for the provision of treatment for tuberculosis.

Ultra-Violet Rays.—On May 17th Mr. Chamberlain, Minister of Health, informed Mr. Day that he had not received any evidence of injury resulting from the use of ultra-violet rays by unqualified persons. If the hon. member was aware of any specific cases in which such injury had arisen he would be glad if he would furnish him with particulars with a view to further inquiry.

Naval Appeal Tribunal.—On May 17th, Mr. Bridgeman, First Lord of the Admiralty, told Sir B. Falle that very careful consideration had been given to the question of an independent appeal tribunal for officers and men invalided from the navy. The establishment of tribunals to deal with cases arising during the war was an innovation, but it was no doubt justified by the extraordinary conditions of the time—namely, the conscription of the majority of the adult male population, the arduous conditions of war service, and the difficult and complex medical questions involved. Under post-war conditions the same necessity did not, however, exist. Under existing conditions the service medical history of every man was well known, from the date of entry onwards throughout his career. The duties expected of him and the conditions under which they were performed were well known to the medical officers of the service, and he could not admit that any outside tribunal or referee was more competent to determine whether a man was physically fit for retention in the service or not, and whether a disease was attributable to the service or not, than they were. The decisions of local surveying officers were always subject to review by the medical authorities of the Admiralty, and any officer or man who was aggrieved by the decision in his case could appeal to the Board of Admiralty, with the result that his case was thoroughly investigated again. He felt sure that, on reflection, Sir B. Falle would agree that it would be quite impracticable to remit the question whether an officer or man was fit for retention in the fighting force to any authority outside the department. As to the other issue, the hon. member could not fail to recognize that the surveying medical officers were independent and unprejudiced judges, who could not have any personal interest whatever in the matter in preventing them from giving each case the most sympathetic consideration possible. He was, therefore, convinced that there was no justification for establishing a general right of appeal beyond the Board of Admiralty in these cases, and though he undertook to consider the possibility of making exceptions to the general rule in special cases, he found it impossible, after full consideration, to support any such proposal. Satisfied as he was that a general right of appeal was unnecessary, he had come to the conclusion that to single out any one or more diseases as affording grounds for exceptional treatment could have no other result but to create a sense of grievance among those who were invalided for other diseases or injuries. He had consulted the Secretary for War and the Secretary for Air, and they, fully,

endorsed the conclusions he had reached. He regretted, therefore, that he could not recommend any departure from the present rule that the decision of the Board of Admiralty must be final.

Hours of Work in Industry.—On April 30th Mr. Mackinder moved the second reading of the Hours of Industrial Employment Bill, whose purpose was to provide a forty-eight hour week for all persons employed in industrial undertakings. Dr. Drummond Shiels drew attention to the researches of the Industrial Fatigue Research Board, working under the Medical Research Council, and quoted from the report by Dr. Vernon on "The significance of output in industrial efficiency," which appeared in the report of the Board for 1924. Dr. Vernon reported that reductions of hours in munition works were followed by improvement in working speed, but that three or four months were required to gain equilibrium with the shortened hours. Sickness time fell off steadily with the reduction of hours in munition works, and in the last three years lower rates of sickness had been shown in factories where a forty-four hour week was worked. Dr. Shiels thought these researches suggested that the working efficiency of the country would not be reduced by the passage of the bill before the House. Dr. Vernon Davies said that varying industries received their maximum efficiency from varying hours of labour. There should be a scientific particular question, and also into the would pay employers to inquire seriously workpeople and see that the hours worked were economically the best. Mr. Betterson (Parliamentary Secretary, Minister of Labour) said that the Conference of Ministers of Labour from Western European Countries which met in London had presented a report on hours of labour just after Easter. This report was before the Government. It raised great difficulties, but would receive very careful consideration. He suggested that to press the bill might prejudice the issue. The House divided, and rejected the bill by 186 to 119.

Railway Accidents during the Strike.—On May 18th, Colonel Ashley, Minister of Transport, told Mr. C. R. Morrison that between May 4th and 14th the railway companies reported the occurrence of six accidents to trains. As a result, four persons were reported to have been killed and thirty-five injured.

Notes in Brief.

A general memorandum under the Clean Meat Regulations has been issued to all meat traders in Southwark.

There were 244 deaths due to influenza in London in January, February, and March of this year.

The Minister of Health states that he hopes it will be possible to introduce a Rural Housing Bill this session.

Universities and Colleges.

NATIONAL UNIVERSITY OF IRELAND.

A MEETING of the National University of Ireland, for the purpose of conferring degrees and other academic distinctions, was held on May 15th in the Council Chamber, Earlscourt Terrace, Dublin. Dr. Denis J. Coffey, President of University College, Dublin, and Vice-Chancellor of the University, presided.

The following degrees and diplomas were conferred:

M.D.—E. T. Freeman, D. A. MacErlan.
M.B., B.Ch., B.A.O.—P. H. Cummins, O. F. Carey, J. Coghlan, J. J. Craig, T. Daly, E. R. Devlin, Alice M. Duff, T. Duff, P. Dwyer, J. P. J. Kelly, Kato A. Moran, Marguerite S. O'Mahony, Eileen M. O'Neill, J. I. N. O'Sullivan (*in absentia*), K. Phelan, T. J. A. Ryan, J. Vesey, G. J. Waters.
D.P.H.—J. J. McCann, Mary J. McEvoy.

UNIVERSITY COLLEGE, GALWAY.

The following degrees and diplomas were conferred on May 12th:

M.D.—A. J. W. Compton (*in absentia*).
M.B., B.Ch., B.A.O.—T. W. McDonagh, M. McEnroy (*in absentia*), P. Nanghion, O'Sullivan.
D.P.H.—J. O'Dea, B.Sc., M.B.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A MEETING of the comitia of the Royal College of Physicians of London was held on May 13th, when the President, Sir John Rose Bradford, was in the chair.

Fellowship.

The following, having been elected to the Fellowship at the meeting on April 29th, were admitted as Fellows:

Sir Henry John Forbes Simson, K.C.V.O., M.B.Ed., Wilfred Edgecombe, M.D.Lond., Harold Pritchard, M.D.Lond., Frederick George Thomson, M.D.Lond., William Johnson, M.C., M.D.Lond., Charles Wilfred Vining, M.D.Lond., Richard Robins Armstrong, M.D.Camb., John Josias Conybeare, M.D.Oxf., John Cuthbert Matthews, M.C., M.D.Camb., Julian Lionel Priston, M.B.Lond., John Alexander Drake, M.D.Lond., Francis Richard Fraser, M.D.Ed.
Under By-law XL (b): Arthur Edwin Boycott, M.D.Oxf., John Thomson, M.D.Ed.

Two licences were granted.

Sheffield University Celebration.

Professor Arthur J. Hall was appointed representative of the College at the forthcoming celebration of the coming of age of the University of Sheffield.

The following additional by-law, having been moved for the

second time by the Registrar, was passed:

Joint Examining Board or he character, conduct, or on which, in the opinion of the Board, it is desirable to decline to examine a candidate for admission to the College shall be submitted to them by

The President then dissolved the comitia.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

An ordinary Council meeting was held on May 13th, when the President, Sir John Bland-Sutton, was in the chair.

Fellowship.

Mr. George Buckston Browne and Mr. Thomas Herbert Bickerton were introduced and admitted Fellows.

Walker Prize.

Dr. William Ewart Gye was introduced and presented with a cheque for £100 (the Walker Prize for 1921-25), together with a document declaratory of the award.

Cartwright Medal.

Dr. J. Sim Wallace was introduced and presented with a cheque for £85 and the Cartwright Medal in bronze, together with a document declaratory of the award.

Diplomas.

Diplomas of Membership were granted to 190 candidates. (The names were published in the report of the comitia of the Royal College of Physicians of London, published in our last issue, p. 851.)

Appointment of Representatives.

Sir H. J. Waring was appointed to represent the College at the celebration on June 10th and 11th next of the bicentenary of the foundation of the Faculty of Medicine of the University of Edinburgh.

Sir Berkeley Moynihan was appointed delegate to the celebration, on June 30th, July 1st and 2nd, of the coming of age of the University of Sheffield.

Conjoint Examinations.

A report from the Committee of Management was read and adopted. (An abstract of the report was printed in the report of the comitia of the Royal College of Physicians of London, published in our last issue, p. 852.)

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

At the monthly business meeting of the President and Fellows, held on May 7th, Michael Gallagher was admitted to the Licences in Medicine and Midwifery of the College.

The following were nominated for Professorships in the schools of surgery of the Royal College of Surgeons in Ireland: *Midwifery*, Andrew Hope Davidson, M.D., F.R.C.P.I.; *Medicine*, George D. Nesbitt, M.D., F.R.C.P.I.; *Pharmacology*, Leonard Abrahamson, M.D., F.R.C.P.I.

Dr. Thomas Gillman Moorhead, Regius Professor of Medicine in the University of Dublin, was appointed to take the place of the King's Professor of Materia Medica and Pharmacy as visiting Physician to Sir Patrick Dun's Hospital.

The Services.

TERRITORIAL DECORATION.

THE KING has conferred the Territorial Decoration upon the following officers of the R.A.M.C.(T.A.): Lieut.-Colonels Alfred W. Moore, O.B.E., and Philip H. Mitchiner; Majors W. F. Denning, H. E. S. Richards, M.C., and A. L. S. Tuke, M.C.; Captain (Major Prov.) H. Pinto-Leite; Captain A. C. M. Savage.

DEATHS IN THE SERVICES.

Fleet Surgeon Hugh Winckworth Macnamara, R.N.(ret.), died at Peppard, near Reading, on April 16th, aged 66. He was educated at Newcastle-on-Tyne and Westminster Hospital, and after taking the M.R.C.S. in 1880, and the L.R.C.P.Lond. in 1882, entered the navy as surgeon on August 21st, 1883, attaining the rank of fleet surgeon in August, 1903, and retiring on December 10th, 1913. He had seen service in most parts of the world. Soon after entering the navy he served in the dispatch boats *Helican* and *Surprise* in the Mediterranean. The Duke of Edinburgh, who was then Commander-in-Chief in the Mediterranean, often used the *Surprise* for paying official visits. He next served on the *Excellent* in the gunnery school at Portsmouth, in 1890-93, and later at Gibraltar, and on the *Cordelia* in the West Indies. When the Orient liner *Ophir* was transferred temporarily to the navy, and fitted out to convey the King and Queen, then Prince and Princess of Wales, to India in 1901, Macnamara was her principal medical officer. He afterwards served in China, on the *Albion*, and in the *Royal Arthur* and *Euryalus* in the West Indies; in June, 1910, he joined the *King Alfred* in the Home Fleet, and from September, 1912, till his retirement, fourteen months later, was on the *Lion*, Admiral Beatty's flagship.

HERBERT JONES TESTIMONIAL.

We published in our last issue the second list of subscriptions to the fund started by the Herefordshire Medical Society to recognize the great work done by Dr. Herbert Jones for the profession and for the public health services in particular. We have now received from Dr. John Steed (Stannington-Wye, Herefordshire), the honorary treasurer of the fund, a third list, with an intimation that it is proposed to close the fund at the end of this month. We hope that before this its dimensions may be considerably increased.

THIRD LIST.

£5 ss.—Dr. R. Veitch Clark.
£2 ss.—Dr. R. A. Dunn (Hereford). *Lieut.-Colonel F. E. Fremantle,
M.P., Drs. C. Richards (London), W. H. Hill
(Oxford). *
£1 ss.—Drs. lical Secretary, British Medical
Association, Benton, C. S. Brebner (Rich-
mond, Surrey), C. R. Gibson (Guilford),
*A. Wellesley, N. T. K. Jordan (Beecon),
*A. J. Lavid, *S. C. Mostyn, *A. A. Mussen, G. H. Pearce (Batley),
*R. M. F. Picken, R. W. C. Pierce (Guilford), *Wiltland Radford,
*W. Sison, *C. O. Stallybrass, *John Tate, Alfred E. White (Wellington).
10s. 6d.—Drs. J. H. Garrett (Cheltenham), *M. C. R. Grahame, Algenon
E. L. Wear, C.M.G. (Leeds).

*Through the Editor of *The Medical Officer*.

Medical News.

THE next session of the General Medical Council will commence on Tuesday, June 1st, when the President, Sir Donald MacAllister, Bt., K.C.B., M.D., will take the chair at 2 p.m.

DR. F. J. BROWNE, assistant physician to the Edinburgh Royal Maternity Hospital, whose important paper on the etiology of accidental haemorrhage was published in our issue of April 17th, has been appointed to the University Chair of Obstetric Medicine tenable at the Medical School of University College Hospital, London.

THE lecture by Professor Joseph Barcroft, F.R.S., on recent work on the spleen, which was announced to be given on May 6th at St. Mary's Hospital Institute of Pathology and Research, Paddington, W.2, has been postponed till Monday, May 31st, at 5 p.m.

A MEETING of the Fever Hospital Medical Service Group of the Society of Medical Officers of Health will be held at 1, Upper Montague Street, Russell Square, W.C.1, on Friday, May 28th, at 3 p.m., when Dr. J. E. McCartney, Director of Research Laboratories, Metropolitan Asylums Board, will read a paper on some problems in infectious diseases.

THE Cavendish Lecture will be delivered before the West London Medico-Chirurgical Society by Professor G. Elliot Smith, M.D., F.R.S., on Friday, May 28th, at 8.30 p.m. at the Kensington Town Hall, and will be followed by the annual conversation of the society. The subject of the lecture is "Vision and evolution." It will be preceded by a reception by the President at 8 o'clock. Tickets may be obtained for members of the medical profession and their friends through members of the society.

AT the next social evening of the Royal Society of Medicine, which will take place on June 1st, Mr. Frederick Horday, O.M.G., F.R.C.V.S., president of the Section of Comparative Medicine, will give an illustrated address on "Our animal friends as patients."

IN connexion with the postponed Nation's Health Exhibition at Leicester, which will now open on May 26th, a conference has been arranged by the British Social Hygiene Council for June 3rd, at 2.15 p.m., when Colonel L. W. Harrison will give an address and show the film he has prepared for the council to illustrate the diagnosis and treatment of syphilis. The conference will consider later in the afternoon what further steps can be taken to prevent congenital syphilis, and the opening address will be given by Dr. N. Cruickshank.

AS already announced, the twelfth International Physiological Congress will be held at Stockholm on August 3rd and three following days. The subscription of a member is twenty Swedish crowns, and this and all other communications with regard to the congress should be addressed to the Secretary, Dr. G. Liljestrand, Karolinska Institutet, Stockholm, Sweden. A typewritten abstract, of not more than 280 words in length, of any paper proposed to be read should be sent to him not later than May 31st. The Swedish consulates will visé passports free of cost on production of the membership receipt. Particulars about travelling rates and tours can be obtained from the office of the Swedish State Railway, 21, Coventry Street, W.1.

DR. ALDO CASTELLANI has returned from America, where, at the invitation of the authorities of the Tulane University, New Orleans, he organized a tropical medicine division in the Medical School. During his visit he delivered the Gehrman Memorial Lecture series at the University of Illinois; and at the annual meeting of the American Medical Association at Dallas, Texas, last month was awarded the gold medal, the highest recognition which can be given by the association. The award "was based on the excellent investigation in comparatively unexplored fields of medicine and for the perfection of the display" of specimens in the annual medical exhibition.

THE seventh annual International Neurological Reunion, organized by the Neurological Society of Paris, will be held on June 1st and 2nd at the Salpêtrière. The subject of discussion will be the clinical methods of examining the sympathetic system and their value. Further information may be obtained from the general secretary of the Neurological Society, Dr. O. Crouzon, Librairie Masson et Cie, 120, Boulevard St. Germain, Paris VI. This reunion will follow a congress on legal medicine in Paris, on May 27th to 29th, and the annual reunion of the Medico-Psychological Society on May 31st.

A PARTY of medical students from the University of Birmingham visited the brine baths at Droitwich, under the guidance of Dr. Douglas Stanley, on Saturday, May 15th. The methods of using natural brine baths were explained by members of the medical profession in Droitwich and by representatives of the baths management.

ACCORDING to *La Medicina Ibera*, although medical instruction at Lisbon can be traced back to the Middle Ages, the faculty of medicine, whose centenary was recently celebrated, was not founded until 1825, in the reign of Juan VI. The faculty now possesses twenty chairs, including one for medical ethics.

PROFESSOR ETTORE MARCHIAFAVA has recently received a gold medal from the Italian Government for his services to public health.

A CHAIR of medical jurisprudence and social medicine has been founded at the medical faculty of Lille University.

ACCORDING to the *Revue Franco-Russe de Médecine*, there are 5,163 medical practitioners in Leningrad without employment.

DURING 1925 612 cases of epidemic encephalitis were notified in the Ukraine, the largest number being at Ekaterinoslav, Pavlograd, and Zaporozie.

THE Cambridge University Press announces for early publication a book by Dr. Henry Head on *Aphasia and Kindred Disorders of Speech*, in two volumes. Volume I contains an historical sketch of the progress of knowledge in this subject, an account of the new methods of examination employed by Dr. Head, and the results of his clinical observations. Further sections are devoted to cerebral localization of function and to theoretical conclusions as to the nature and causes of aphasia. Volume II gives a series of clinical reports of cases each of which illustrates one or more aspects of the problems dealt with in volume I.

THE Office International d'Hygiène Publique has recently published some interesting information relating to the prevalence and mortality of scarlet fever in Bulgaria, Czechoslovakia, Poland, Manchuria, and South Africa, supplied by the official delegates of those countries. Dr. Ivan Golosmanoff, the Bulgarian delegate, provides a table of the incidence of scarlet fever in Bulgaria during the last twenty years which shows that the annual average of cases from 1906 to 1922 was 4,200. In some years, such as 1907, 1914, and 1923, the disease assumed an epidemic character, and 6,355, 6,923, and 15,913 cases were notified. The annual average mortality from scarlet fever in Bulgaria has ranged from 12 to 20 per cent. The fact that the mortality was higher in one department (Petrich), where there was no hospital, seems to indicate that hospital isolation has some influence in lowering the mortality. According to Dr. Prochazka, the delegate from Czechoslovakia, there has been a considerable fall in the mortality of the disease in that country within the last thirty years (from 20 per cent. in 1893 to less than 5 per cent. after the world war). It is claimed that owing to more careful medical attention the mortality has always been less in Bohemia than in Moravia and Silesia. The death rate in Poland is relatively high; Dr. W. Chodzko states that since 1919 the mortality has ranged from 8.7 to 13.2 per cent. The value of vaccine prophylaxis is illustrated by the fact that of 2,654 children who received Gairitchewsky's vaccine only five contracted the disease. Four of these had a very mild attack and one died of pneumonia. On the other hand sixteen of those who were not vaccinated contracted scarlet fever in the course of the next six weeks. Dr. Tsurumi, the Japanese delegate, reports that in Manchuria the mortality from 1911 to 1919 ranged from 2.5 to 23.8 per cent., and states

that there were grounds for the belief that the disease had been introduced by the Russians during their occupation of the country. Not the least interesting of the reports is that by Dr. J. A. Mitchell, Director of the Health Service of the Union of South Africa, who states that the disease is almost exclusively confined to the European population, and that the natives are almost entirely refractory to it. On the whole the character of scarlet fever appears to be milder in South Africa than in Great Britain. The season and climate have a considerable influence on the predominance of the disease. Epidemics invariably occur in the cold months of the year, and the activity of the disease invariably declines when the hot weather commences. Scarlet fever is most prevalent in Capetown; at Port Elizabeth, where the climate is a little warmer, it is considerably less prevalent; at East London, where it is hotter still, there is even less scarlet fever; and lastly at Durban, where the climate is semi-tropical, the disease is relatively rare, except among children who have come from Johannesburg or other localities in the High Veldt in the incubation stage.

The sixth annual congress known as the Journées médicales de Bruxelles, which will be held at Brussels from June 26th to 30th, will be presided over by Professor Jean Demoor, director of the Institute of Physiology at Brussels. It is expected that the attendance will exceed that of last year, which was over 1,500. In addition to numerous lectures and demonstrations by specialists from many countries, an international exhibition of applied art and science is being arranged, special classes being reserved for medical journalism and works of art by medical practitioners. The King and Queen of the Belgians will receive the members at the royal castle of Laeken; a dinner will be held in honour of Marshal Lyautey in appreciation of his services to medical progress in the French colonies; and a performance will be given of Rimsky-Korsakov's *Le Tsar Saitan*. Further information may be obtained from Dr. R. Beckers, 62, rue Froissart, Brussels.

A SOCIETY for the study of the history of medicine has recently been founded at Lemberg in Poland.

DR. GREGORIO MARAÑÓN has been elected president of the Spanish Médico-Chirurgical Academy.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **BRITISH MEDICAL JOURNAL** alone unless the contrary be stated. Correspondents who wish notices to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **BRITISH MEDICAL JOURNAL** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the JOURNAL, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the **BRITISH MEDICAL JOURNAL** are **MUSEUM 9861, 9862, 9863, and 9864** (internal exchange, four lines).

THE TELEGRAPHIC ADDRESSES are:

EDITOR of the **BRITISH MEDICAL JOURNAL**, *Antiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER

(Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Facillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumshengh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

LETTERS, NOTES, ETC.

LIGHTNING PAINS IN TABES.

DR. S. E. DEXTER (Hull) sends the following note: Dr. Washington Isaac (*JOURNAL*, May 1st, p. 814) writes of a patient who suffers severely from the lightning pains of tabes dorsalis. May I suggest that he tries 10 or 15 grain doses of acetylsalicylic acid. For several years I was in medical charge of a home for chronic cases, most of which were nerve cases, and one of them, a patient with tabes, suffered at times most severely from lightning pains; this went on for some years. He was always much more benefited by 10 grains of acetylsalicylic acid than by any other drug. It relieved his pain much more quickly than even an injection of morphine, which, indeed, he would refuse if he could get the other drug.

ECHINOCOCCAL CYSTS IN CAMELS.

DR. J. BURTON CLELAND (Professor of Pathology, University of Adelaide) writes: In reference to Dr. J. C. Milne's note (*BRITISH MEDICAL JOURNAL*, December 19th, 1925, p. 1206) in connexion with this subject, and the reply of Dr. G. W. Sudlow (January 9th, 1926, p. 76), the following further references may be of interest.

In an article entitled "Trypanosomiasis and other diseases in camels" (*Transactions of the eighth session of the Australasian Medical Congress*, 1903, vol. ii, p. 305, and also *Bulletin No. 34, Department of Agriculture, Western Australia*, 1909) I have recorded the occurrence of hydatid cysts in four camels which had recently been imported into the north-western part of Australia from Karachi in India. The following is an extract from this paper:—

Other Animal Parasites found in the Imported Camels.

"Hydatids (*Taenia echinococcus*).—In post-mortem examinations on four of the camels hydatid cysts were found in each. In one there were about a dozen cysts, some as large as a goose's egg, in the lungs. In the other three there were up to half a dozen, ranging to the size of a hen's egg. Single cysts were found in the livers of two. Two of the cysts were degenerating and becoming calcified. In one a large number of daughter cysts, about the size of a grain of sago, were present. In some brood capsules were conspicuous. Scolices were numerous, and also the rounded concentric bodies like starch grains. Considering the number of cysts present, and the fact that two were degenerating, it hardly seems possible that the camels can have gained the infection in Western Australia during a stay of five months, especially as, in the only two bullocks I have seen slaughtered here, the liver and lungs were unaffected, and stockmen here are not apparently aware of the presence of hydatids in this part."

UTERINE AND MAMMARY CANCER IN HOLLAND.

PROFESSOR H. W. METHORST, director of the Dutch Central Statistical Bureau, and Dr. H. T. Deelman, who recently have investigated the mortality due to uterine and mammary cancer in Holland, have published a statistical summary of their results in the *Nederlandsch Tijdschrift voor Geneeskunde* (1926, p. 1178). The general death rate in Holland is stated to have shown a regular and well marked fall since the middle of last century (from 25.56 per 1,000 in 1840-49 to 9.60 in 1924). The birth rate also showed a regular, though less pronounced, decline (from 33.54 to 24.89). The mortality from various causes was generally diminished, but not from cancer; this might perhaps be attributed in part to more correct diagnosis; longer duration of life might also be a factor, since cancer shows a predilection for the elderly. As in other countries, the mortality from mammary cancer is constantly higher in the unmarried than in the married; while uterine cancer is much less frequent among the unmarried, cancer of the body of the uterus shows a preference for unmarried and childless old women, while cancer of the cervix occurs chiefly in young women who have borne children. Since 1905 the mortality from uterine cancer in Holland has risen from 13 to 14.9 per 100,000 of the female population, and the mortality from mammary cancer from 9.9 to 13.3 in 1923. In 1924 the figures were 16.8 and 14.6 respectively. With the exception of North Brabant, where the mortality from uterine cancer has fallen from 10.4 to 10.1, all the provinces in Holland have shared in the increase. The likelihood of death from uterine and mammary cancer generally increases with age. Uterine cancer showed a moderate increase among the unmarried up to the 59th year, and then a fall until the 64th, succeeded by a moderate rise up to the 74th year, followed by a fall until the 79th, and, lastly, a rise after the 80th year. In married women uterine cancer showed a continuous slight rise up to the 69th year, followed by a considerable rise up to the 79th year, when a fall occurred. Mammary cancer in unmarried women showed a pronounced rise in each age group up to the 54th year; this was succeeded by a fall until the 59th year, followed by a rise, except from the 64th to the 69th year. In married women mammary cancer showed a slight rise up to the 59th year, followed by a fall from the 60th to the 64th, and then a slight increase until the 69th year, when the rise became more pronounced.

MEDICAL GOLF.

In the final of the Medical Golfing Society's spring tournament Mr. Joseph Cunliffe defeated Dr. E. Ravensworth Hart at the nineteenth hole, and thus won Mr. T. P. Kolesar's cup.

A BROADS CAMP FOR BOYS.

DR. F. CHAMBERLAIN, secretary to the Cadet Department of the Broads Cruising Association, announces that a camp will be held for public school boys between the ages of 14 and 18 on the Norfolk Broads for a fortnight from Saturday, August 7th. In addition to the provision of a pleasant holiday, full opportunities are given for learning watersmanship and small boat sailing. The charge for the fortnight is 7 guineas, and for one week 4 guineas. Further information may be obtained from Dr. Chamberlain, 127, Aylsham Road, Norwich.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 52, 53, 55, 57, and 58 of our advertisement column, and advertisements as to partnerships, assistantships, and locum tenencies at pages 54 and 55.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 188.

Observations

OR

THE THERAPEUTIC ACTION OF ULTRA-VIOLET
LIGHT UPON THE EYE.

BY

W. STEWART DUKE-ELDER, M.A., M.D., F.R.C.S.

(From the National Institute for Medical Research, and the Ultra-Violet Clinic, Royal London Ophthalmic Hospital.)

Of late years, owing largely to the work of Leonard Hill and his co-workers, the treatment of general disease by ultra-violet light is being rapidly put on a scientific basis, but hitherto no serious attempt has been made in this country to investigate how far it might be utilized in the treatment of diseases of the eye. To this paper, which is a preliminary report of the experience gained at the Ultra-Violet Clinic of the Royal London Ophthalmic Hospital, I must prefix an acknowledgement of my indebtedness to the Medical Research Council for opportunity and financial aid in this work, and to Professor Leonard Hill and Sir John H. Parsons for much stimulating help and encouragement. The preliminary nature of the paper must be emphasized. The method of treatment cannot as yet be said to be altogether out of the experimental stage, and sufficient experience has not yet been obtained to dogmatize absolutely on its indications and limitations, or to assign to it its ultimate value in our therapeutic armamentarium. The present paper is based on the treatment of seventy cases, and it is hoped that later, when larger statistics have been gathered, fuller and more authoritative reports will be published. At the present moment, however, it is felt that results of sufficient interest have accumulated to warrant publication, largely in the hope that the knowledge of them may stimulate others to supplement them out of their own experience.

At present the therapeutic action of ultra-violet light is largely a mystery which presents theoretically many interesting and elusive problems. The clinic has outrun the laboratory, for the stimulating effect of this form of radiant energy upon the normal individual, and its therapeutic influence in many diseased states, cannot be denied. It is already well known that ultra-violet light, particularly of wave-lengths 2,500 to 3,000 Angström units, exerts a very definite biological action on the skin, whose apparent signs are the production of an erythema followed by death and desquamation of the outermost layers, and that thereby activities of great therapeutic value are called into being. These activities are comprised partly of electrical forces set free in the change of potential involved in atomic disintegration, and partly of chemical factors, the result of the destruction or partial destruction of the cell proteins, the products of whose death and disruption, being set free into the general circulation, increase the non-specific immunity of the body, much in the same manner as the production of homoproteins presumably plays the leading part in the chemical mechanism of defence and immunization against disease generally. In the benefits of these activities the eye shares in common with the rest of the body.

In the treatment of eye diseases ultra-violet light may be utilized in two ways: applied as general light baths to the skin of the body generally, or applied locally to the eye itself. We shall refer to the first as "general phototherapy," to the second as "local phototherapy."

GENERAL PHOTOTHERAPY.

The technique employed by the writer in the administration of general light baths is based on that elaborated by Leonard Hill and Eidinow⁷ at the National Institute for Medical Research. This method of procedure aims at giving the optimum intensity of radiation over the optimum area of body surface as gauged by the estimation of the bactericidal power of the blood. So far as we are aware at present, this is the only systemic effect of radiation which submits itself to scientific estimation on whose basis we can regulate our treatment. Hill, Eidinow, and Colebrook⁸

have shown that after exposure to ultra-violet light this property of the blood is increased, sometimes to a marked degree, the effect being due in large measure to the formation and biological action of photochemical products liberated from the leucocytes. Further, Colebrook⁸ has demonstrated that excessive dosage diminishes the haemo-bactericidal power, an effect which can be correlated with the mental and physical depression which too large doses of ultra-violet light almost invariably produce. The total effect produced varies with the intensity of the radiation and the area of skin exposed; and, going a step further, Eidinow⁷ has shown that the optimum effect is obtained with radiation of such intensity as produces a mild erythema extending over an area of about one-quarter of the body surface.

Individuals vary largely in the degree of their susceptibility to light, and therefore the routine procedure adopted is to estimate first the reaction of the patient by a determination of the duration of exposure required to produce the faintest recognizable erythema. This "minimal erythema dose" is obtained by exposing small areas of the inner surface of the arms or of the back to the mercury vapour lamp at about one metre distance for periods of two, three, and eight minutes. The following day the areas are observed, and dosage commenced whose duration is judged from the standard thus obtained. Thereafter, during the course of the treatment, the body is divided into four areas—the chest and front of the abdomen, the back, the front of the legs, and the back of the legs—and each of these is irradiated on alternate sittings. The patient attends the clinic on three days a week, and in this way practically the whole body is irradiated once in ten days. The object of each dose is to produce the faintest perceptible erythema, after which there is a fine desquamation of the cuticle. This desquamating skin is very opaque to the ultra-violet rays, and to irradiate it would be largely a waste of time; further, the newly exposed skin is extremely sensitive, and gives a strong reaction. The ten days' interval between successive treatments of the same part brings the alternating areas up for re-exposure after the stage of desquamation has passed, and when fresh but not too sensitive skin is exposed. By this routine an optimum reaction is obtained automatically over an optimum area; an optimum increase of the haemo-bactericidal power is induced; and with this—as far as we can judge—an optimum general effect is obtained from the course of treatment.

Sensitiveness varies largely with individuals, and moreover with different parts of the body in the same individual; the back and arms are practically always more easily affected than the front of the body. The dose is therefore regulated for the individual, and varied with the area exposed to suit the case. After some time a certain amount of immunity develops. As a general rule the initial dose is two to three minutes with the mercury vapour lamp (K.B.B., atmospheric, 200 volts, 2 to 3 amperes), and works up fairly rapidly to twelve or fifteen minutes, where it remains for a very long time, since the small dose given and the method of alternately resting the skin keeps it in a condition of "light sensitiveness."

CLINICAL CONDITIONS.

As in the other parts of the body, so in the eye, the diseases most amenable to treatment are the chronic inflammatory. This, in fact, is one of the most satisfactory aspects of phototherapy in ophthalmology, for in many of these cases little can be done by the ordinary methods of treatment at our disposal. The experience gained points to the view that in the earlier acute stages general phototherapy very frequently does more harm than good, and that relapses are prone to occur. The best time to commence treatment appears to be immediately after the acute symptoms have passed off, before the disease can be definitely labelled "chronic," and before the lesion is complicated by the accumulation of massive organized deposits, or restoration rendered impossible by extensive tissue degeneration and destruction.

In the eye cure, from the patient's point of view, is placed on a much higher standard than elsewhere in the body. By him the end-result is interpreted in terms of the vision finally obtained, and whereas elsewhere the

formation of a cicatrix is welcomed as a desirable termination deserving to be considered a satisfactory cure, in the eye such a culmination too often renders the organ useless, and is therefore interpreted as a failure. For this reason it is important to get the cases under carefully supervised treatment as early as is safe. In many chronic cases improvement has been slow, and, although in some the rate of progress has been astonishing, in others the treatment has been a question of weeks or months, calling for no little patience on the part of all concerned. Experience has shown that this should never be allowed to tempt one to increase the dosage beyond the limits already outlined. With the ease with which it lends itself to examination, and the importance the patient places upon slight changes in subjective symptoms, the eye lends itself to the appreciation of slight changes for better or for worse more readily than most organs of the body; and I am convinced that the best results are obtained by rigidly refraining from "pushing" the treatment, but rather allowing what is really a natural cure of the disease to act slowly, and gradually, and naturally.

In all cases, almost from the commencement, the marked general tonic effect is evident. Almost invariably, whether the eye condition clears up or not, one is told that the patient feels better and stronger and is generally more fit, that the appetite increases, sleep improves, and weight is put on. Particularly is this seen in children, and more especially in the sun-starved creatures that the hospital largely caters for. Not only is the stimulation confined to the physical state, but usually the mental state responds as well—indeed, in the assessment of the progress of treatment this factor leads one easily astray: the influence of the undoubted psychical effect of the treatment at the clinic, the unfortunate popular belief that ultra-violet light is a cure-all for everything, and the general mental and physical tuning up, delude the patient into thinking that rapid progress is being made, and it is easy for the observer to be led to share in his enthusiasm.

Tuberculous Lesions.

The affection which gives the readiest response is ocular tuberculosis in any of its forms. The importance of this is realized when it is remembered that tubercle of the eye is one of the most depressing and hopeless diseases in ophthalmology. With the methods of treatment ordinarily used the history of such a case is too often one of gradual and relentless deterioration, ending ultimately in blindness or in the excision of the eye for pain. The effect of light treatment at the clinic has been most encouraging, and the patients have uniformly improved from its commencement—as a general rule slowly, sometimes with remarkable rapidity. No case would seem to be too bad to be altogether despaired of, and it would seem not unreasonable to hope that the prognosis of this disease may be completely altered.

Of the 70 cases on which this paper is based, 9 were labelled clinically as tuberculosis—that is, they showed lesions which appeared typically to resemble tuberculosis, had a positive von Pirquet reaction, and other sources of infection were excluded. Eight cases of irido-cyclitis have made, or are making, most satisfactory progress; two examples may be cited.

A woman, aged 37, had had recurrent attacks since 1914; the disease was steadily progressive in spite of all methods of treatment—tuberculin, arsenic, etc.; the left eye was excised in 1920 for pain and raised tension. When ultra-violet light treatment was commenced vision of the right eye was reduced to bare perception of light. After ten weeks' treatment (general and local), intermitted with rest periods, the massive keratitis punctata has completely disappeared, the eye is quiet and white, she can see to get about the streets of London unaided, and is rapidly improving.

A woman, aged 23, who had massive keratitis punctata, ciliary injection, and nodules on the iris, has, after thirteen treatments, a perfectly quiet and white eye, with no clinical pathological evidence.

The remaining case of the nine, a woman aged 23, was of tuberculous dacryocystitis. Five years ago she was under the care of Koller in Switzerland, under whose treatment the disease cleared up. A relapse occurred eight months ago, and in spite of surgical treatment an open discharging wound persisted. After four weeks' treatment the wound has healed, and all signs of activity have disappeared.

Pllyctenular Kerato-Conjunctivitis.

The other disease in which startlingly good results have been obtained is pllyctenular ophthalmia, especially the type which is met with in so chronic and recurrent a form

in the debilitated and sun-starved children of large cities. The ready and rapid improvement in these cases is remarkable; after a few days' treatment most of the distressing symptoms have disappeared and the photophobia has gone; after a few weeks' treatment a child whose eyes have been in a chronic state of intermittent irritation for years will clear up, and the general health will improve in a remarkable manner. Relapses, however, have occurred in a few cases, and the end-results have not been sufficiently long observed to allow one to dogmatize on the permanency of the improvement derived from one course of treatment; but the relapses are easily controlled by a repetition of another course of irradiation. The most satisfactory method of dealing with these cases would appear to be the establishment on a large scale of municipally owned centres in the more congested and badly housed areas of the large cities, where these children could receive at regular intervals throughout the year some of the benefits of the open air and sunshine which they so sadly lack.

Infective Irido-Cyclitis.

Cases of infective irido-cyclitis show on the average a much less dramatic response to ultra-violet light treatment, and a response which varies very much from case to case. Excluding the tuberculous lesions, the series comprises 29 cases, all of which were of considerable severity, and the majority of which were of very long standing before they were referred for treatment at the clinic. Of these, 5 have improved so rapidly as almost to be considered as cured within a few weeks; 12 have shown a slow and steady betterment; in 8, apart from the usual improved general condition, the eye lesion appears to have made little or no progress; and 4 have definitely got worse during treatment. In 3 of these 4 the reason is now obvious—that treatment was undertaken while the disease was too acute. Thus 60 per cent. showed an improvement, of which proportion in 30 per cent. it was extremely satisfactory; 40 per cent. have reacted disappointingly, but the majority of these, it must be admitted, were of very long standing; all were considered as quite intractable to the ordinary methods of treatment, and most were sent only as a last resort. On the average, therefore, the results of treatment, as judged on a statistical basis, are to a high degree unfair. At the present stage sufficient experience has not been accumulated to lay down any definite rules of general value as to the indications or contraindications—if any—on which to base a selection of cases.

Sympathetic Ophthalmitis: Choroiditis.

The one case of sympathetic ophthalmitis which has been treated improved so rapidly that in three weeks the eye looked quiet and the injection and practically all the keratitis punctata had disappeared. Three cases of choroiditis have been treated. One, a case of many years' standing, showed no apparent change; the other two rapid and marked improvement.

It is to be remembered that in all these cases the usual routine treatment with atropine, etc., was persisted in throughout; tuberculin was given to some of the tuberculous cases, arsenic to the sympathetic, and in the infective iritis any focus which could be detected was dealt with, and its removal attempted in the usual manner.

LOCAL PHOTOTHERAPY.

The media of the eye share the property of all living matter of being transparent to some wave-lengths of the energy spectrum and opaque to others. Those waves to which the eye is practically transparent pass through the media without exerting more than a correspondingly negligible effect upon them, either pathologically or therapeutically; it is only those waves which are absorbed which can have any action—a generalization which applies here as elsewhere in the physical universe. In the ultra-violet region of the spectrum it may be taken that all waves shorter than 2,950 Angström units are completely absorbed by the cornea, and that above this level an ever-increasing percentage is transmitted, until at the region 4,600 to 3,150 A.U. practically all are transmitted to the underlying lens and iris. The lens absorbs all radiation incident upon it below 3,200 A.U., practically all that below 3,500,

and continues to absorb an ever-diminishing amount up to a limit which varies with the age and the degree of sclerosis, but which may be taken to average 4,000 A.U.; the retina is reached, therefore, by practically all the incident radiation in this spectral region above 4,000, and by some of the incident radiation down to wave-lengths as short as 3,200. The pigment in the iris absorbs all wave-lengths that fall upon it, and degrades the energy into heat.

That part of the incident energy which is absorbed produces a reaction which may be either thermal or abiotic, depending on the length of wave. By the use of suitable filtering screens it has been determined that in the cornea³ the upper limit of wave-length for abiotic response is about 3,050 for the intensities of radiation that can be used clinically, but since comparatively great intensities are required to produce any observable reaction with rays above 3,000, the latter figure may be taken for all practical purposes as the liminal wave-length. Radiation with rays above this produces a thermal lesion, resulting in a burn if sufficient intensities be used; waves shorter than this produce, after a definite latent period, the characteristic symptoms of photophthalmia, with a typical abiotic tissue reaction of desquamation of the epithelium and destruction or partial destruction of the underlying cells. Not only is there a critical threshold of wave-length, but also of energy intensity required to produce a response, which I have found to be on the average, for the production of a mild reaction, slightly under 2 I.K. (infusoria killing) units—that is, such an amount as is obtained from a mercury vapour lamp (K.B.B., atmospheric; 200 volts, 2 to 3 amperes) at a distance of half a metre in two and a half minutes, which corresponds to slightly less than the intensity required to produce a minimal erythema on the skin. In doses under this intensity, short-waved radiation, while it produces no irritant action, seems to have some therapeutic, and certainly some analgesic, action; doses of this intensity produce a temporary abiotic reaction; higher intensities involve a marked photophthalmia, and may, in extreme cases, result in the production of an opacity, which, although becoming highly vascularized and to a large extent disappearing in a few weeks, is often to some degree permanent.

In the lens³ the radiation which is absorbed causes changes of exactly similar nature in the proteins of its fibres, the long thermal rays more readily than the shorter abiotic. These changes result in the coagulation of its proteins or in an increase in the lability of their colloid system, so that they are more easily coagulable by other influences—an occurrence which involves the formation of an opacity, or the production of a state wherein an opacity may be induced more readily than normally. In the iris, owing to the absorption of the pigment, a thermal effect is easily produced, which completely masks any abiotic action, and involves hyperaemia, congestion, and even the production of an iritis if sufficient intensities be employed; but when the pigment is lacking, as in the albino, or where very mild intensities are used, an abiotic effect can be obtained, since most of the incident energy above 2,950 A.U. reaches it. The lens protects the retina³ so completely that an abiotic reaction here is very difficult to elicit within reasonable limits of intensity of radiation; but the absorption of the pigment makes it easy to produce a marked thermal lesion even with the shorter visible rays.

In radiating the eye directly, therefore, when an irritant effect on the cornea, conjunctiva, or lids is aimed at, rays shorter than 3,000 A.U. are used, or, in practice, the whole of the spectrum from the mercury vapour lamp. When a mild abiotic effect or an analgesic action on the cornea is desired, rays of 3,000 and longer are used; the mercury vapour lamp has two strong bands at 3,020 and 3,050 A.U. In radiating the interior of the eye the infra-red rays are inadmissible in any quantity, owing to their potent action in causing opacity in the lens and destructive thermal lesions in the retina and iris. The visible rays are also inadmissible on account of their discomfort, due to glare, and, when in great intensity, of their heating effect on reaching the pigment of the retina. The region of the spectrum between 3,000 and 4,000 would appear to be the least noxious, since here the heat effect is at a minimum, the luminosity

is low, and there is still a considerable amount of abiotic energy, although not of a strength so great as to exceed the threshold for producing the distressing symptoms of photophthalmia. It might be argued that to use these indiscriminately would be reasonably safe, especially in the relatively small and intermittent doses used clinically, derived from sources of small extensity subtending a small solid angle, and therefore involving no great energy concentration in the lens; but these waves are to a large extent absorbed by this tissue, and it is very probable that in the formation of all forms of cataract the common and fundamental process is the absorption of radiant energy²; moreover, in the present case we are dealing with pathological eyes wherein lenticular degeneration readily occurs. All rays, therefore, should be controlled so that the lens is excluded from their path of incidence.

Passow¹¹ has recently sought to overcome the difficulty of obtaining a strong abiotic effect without the attendant photophthalmic symptoms by the use of visible light with sensitizers (Bengal blue, etc.), and Löwenstein¹⁰ and others have used fluorescein in a similar manner. Our knowledge, however, of the action of sensitizers is at a stage when their use should be resorted to with caution, for, although good results may be obtained at the time, unpleasant after-effects may possibly ensue. The formation of cataract by the injection of these substances has been referred to elsewhere,³ and Leonard Hill and Campbell,⁶ on similar treatment of the mesentery, constantly found the formation of capillary thromboses. Even on the local application of such substances to the surface of the cornea it is more than probable that they will be rapidly absorbed into the interior of the eye, when we consider the rapidity with which substances such as atropine, when administered externally as drops, are found to act upon the iris. Until, therefore, substances with a higher selective bacterial affinity are elaborated, the use of sensitizers would appear to be fraught with possible immediate danger to the retina, and probable ultimate danger to the lens.

The technique I employ is as follows. The mercury vapour lamp is used in preference to any form of carbon or metallic arc, owing to the smaller emission of heat rays. In diseases of the lids and conjunctiva, where an irritant abiotic effect is desired, a screening apparatus bearing a quartz director 8 in. long and curved half an inch from the tip at an angle of 140 degrees, concentrates all the emitted rays from the mercury vapour lamp into a parallel beam issuing from the director tip. The director is carried by a flexible spring holder, so that there is considerable play at its distal end, with which the cocaineized and everted lids are slowly massaged, sufficient pressure being applied at the same time to render the parts temporarily anaemic. It has a rounded end, so that it can be inserted into the recesses of the fornices. In conditions such as trachoma, where a stronger effect is desired, the lids are everted and held so as to cover up the cornea completely, and the direct light of the lamp concentrated on the conjunctiva at a focus by a lens system of quartz. In the treatment of corneal lesions, where a similar irritant action is required, the director is held obliquely almost touching the cornea, its bent tip being at such an angle that none of the rays reach the pupillary aperture. Where an irritant effect is not required, but a mild abiotic and sedative action, filtered light is obtained by passing it through a Chance's filter and concentrating it to a focus with an ordinary glass lens, rays above 5,000 A.U. and below 3,000 being thus excluded.

It has been shown that the dose of light necessary to produce pathological effects visible microscopically on the cornea is slightly less than that required to produce a minimal erythema on the skin. The latter standard is therefore first obtained, and the local dose thus gauged. In conditions where the urgency of the case forbids waiting for the twenty-four hours necessary to obtain this standard (as in corneal ulcers) the average dose of two and a half minutes at the working distance (1/2 metre) is given, and the individual dose calculated in the usual way in the meantime. Local treatment is usually accompanied by a course of general light baths should the condition at all seem to require it, these reinforcing its action, and giving the patient the benefit of the general tonic effect.

We propose to differentiate the treatment of the external

eyo (the cornea and conjunctiva) and the lids from that of the internal eye by the terms "external" and "internal" phototherapy.

EXTERNAL PHOTOTHERAPY.

Diseases of the Lids.

Chronic blepharitis, squamous or ulcerative, has been found to respond extremely well to ultra-violet therapy, especially the type so commonly met with in debilitated children, which is characterized by continual relapses, and lack of response to the usual local medicaments. In young children the quartz director is used to the overted lid margin; in older people light is concentrated thereon by the quartz lens. In some cases complete healing results from one or two applications of ten minutes to a quarter of an hour; in all those treated cure was eventually obtained. In the more chronic cases, after some months, lashes which have fallen out regrow.

Diseases of the Conjunctiva.

In the treatment of diseases of the conjunctiva the reaction aimed at is one of tissue irritation and destruction, and coincidentally of bacterial destruction. Initial doses of five minutes are given, and the patient is seen the next day and the effect observed. If the reaction is good its subsidence is awaited; if not, a dose of ten, fifteen, twenty, or even thirty minutes is given, depending on the lesion. In doses of five minutes' duration an acute conjunctivitis starts in about eight hours, and lasts for forty-eight hours; after high doses of thirty minutes the latent period is shorter, and the inflammatory symptoms may remain for a week. A whitish-yellow false membrane forms which, if an attempt is made to remove it, re-forms during the first few days, but which ultimately falls off, leaving fresh unscarred conjunctiva exposed. The absence of corneal damage does away with the distressing symptoms of photophthalmia, and the patient is little incommoded.

Chronic catarrhal conjunctivitis, in the two cases treated, cleared up after six and eight sittings. Three cases of *trachoma* have given most satisfactory results. An acute exacerbation in one case cleared up after two applications; the other two have very much improved after six sittings, the effects of which compare very favourably with the deep scarring caused by prolonged copper applications. One case of *vernal catarrh* showed slow but very satisfactory progress.

Diseases of the Cornea.

In the treatment of corneal lesions one of two effects may be aimed at—an irritating effect on the tissues produced by the shorter waves, or a sedative effect produced by the milder abiotic influence of rays over 3,000 Å.U.

Corneal ulcers have been found to respond very favourably to treatment by radiation; especially is this so in the case of marginal ulcers. The two cases of hypopyon ulcer so far treated became quite quiet after the third exposure. The quartz director is used, and a beam of unfiltered light is played obliquely over the ulcer, the time of exposure being regulated to be slightly less than that required to produce a minimum erythema on the skin of the back or the inner surface of the arm. If the condition appears so urgent that it is not desirable to wait for this, an average initial dose is given arbitrarily of two and a half minutes at the distance worked at (1/2 metre), and the individual dosage calculated in the usual way in the meantime. The ulcer heals with a considerable amount of localized opacity formation, which becomes highly vascularized, and to a large extent clears up, thus corresponding in its behaviour to the opacities produced on the experimental irradiation of the cornea of the rabbit.⁹ It is possible that the therapeutic action is largely one of irritation and increased vascularity, but it is also probable that abiotic action, involving the production of photochemical products from the injured corneal cells, play a part also. Hertel⁸ demonstrated that bacteria suspended in a quartz cell in the anterior chamber were rendered immobile by ultra-violet light; but Verhoeff and Bell,¹² on the other hand, showed that these rays cannot kill bacteria within the cornea without causing severe injury to that structure. Confirming this, I have found that the freshly excised cornea of the rabbit completely protects staphylo-

cocci sown on agar from the lethal action of light, and also that if the anterior chamber is injected with a culture of the same organism, and thereafter the eye be exposed to radiation of an intensity which causes the formation of a definite opacity, the aqueous shows on culture a growth no less abundant than that obtained from unirradiated controls. It is probable, therefore, that direct killing by ultra-violet light of the bacteria responsible for the ulcer does not enter largely into the question, and it is here especially where a sensitizer—could a safe one be found—which would attach itself to bacterial protein in preference not only to the corneal tissue but also to blood, would be of immense advantage.

Corneal opacities have been reported as partially clearing up with ultra-violet radiation. While it is possible that the increased vascularity which follows radiation might have this effect in a recent condition, I have so far been unable to substantiate this claim.

Phlyctenular keratitis, in addition to being treated with general baths, is much benefited by the local application of light. One striking feature is the almost immediate, although temporary, relief which radiation with the filtered rays brings on in the photophobia and blepharospasm.

Interstitial keratitis, to judge from the ten cases treated, is little influenced either by general or by local treatment, although the photophobia is relieved, and the general condition much improved.

Acne, on the other hand, responds very favourably to the treatment. In the two cases treated, the distressing and damaging lesions on the cornea were greatly benefited, and recurrences have been so far warded off. Short exposures with the quartz director, or longer exposures to filtered rays, together with skin baths directed especially to the associated lesions on the face, have been found to clear up both the eye and the facial condition. Where, however, dense corneal opacity and infiltration have been caused by repeated attacks, these residua have remained while the active process has died down.

One case of *episcleritis* of unknown etiology completely resolved after three radiations of five minutes' duration of unfiltered light concentrated by a quartz lens.

INTERNAL PHOTOTHERAPY.

A number of writers on the Continent have reported very favourably upon the treatment of *iritis* and chronic *irido-cyclitis* by local radiation alone; Koeppel,⁹ using filtered and concentrated long ultra-violet rays, is particularly enthusiastic over this method of treating tuberculous lesions, and with its use he has obtained very satisfactory results. I have never yet relied upon this method alone, since it seems reasonable to add to any effect it may have the undoubted aid of general baths. In three cases of *iritis* which were being treated by general phototherapy, periods of a fortnight were selected, when, in addition to the general treatment, filtered rays were focused upon the iris for periods of ten minutes three times a week. In each case the patients asserted that considerably more improvement followed than by raying the skin alone, and the appearance of the eyes certainly did not belie their statements.

Choroiditis and *chorio-retinitis* have been similarly treated locally by Koeppel,⁹ Poyales,¹² Birch-Hirschfeld,¹ and Stock,¹³ and they report good results. It would seem, however, that caution is to be observed in such treatment; general light baths do such patients good, and it seems that to focus light of an abiotic nature into the eye in such intensity that it will have any marked action is running an unjustified risk of laying down future trouble in the lens.

Up to the present the procedure adopted has been to accept for treatment any case that promises to do well at all, and all cases wherein the usual methods of therapy have failed. Such a method of selection obviously involves a proportion of disappointing results, since advanced and almost hopeless cases predominate; but the failures are no less valuable than the successes. Later, when methods of technique have been standardized, and results of greater statistical value have been collected and are compared with those of others, it would seem reasonably safe to predict that an agent of considerable value will have been added

to our therapeutic armamentarium—an agent which, although not by any means a general panacea, is the more valuable in that many of its successes are those very chronic and difficult cases in which the prognosis has hitherto been so hopeless.

A bibliography of the literature of ultra-violet therapy in ophthalmology is appended.

It is a pleasure to thank the members of the staff at Moorfields for their cordial assistance and advice, and for according me the privilege of making use of and reporting their cases.

DEATH FROM FULMINATING PNEUMONIA AFTER
BRIEF NITROUS OXIDE ANAESTHESIA.

BY

ERNEST GLYNN, F.R.C.P.,

PROFESSOR OF PATHOLOGY, UNIVERSITY OF LIVERPOOL; PATHOLOGIST TO
THE ROYAL INFIRMARY, LIVERPOOL; HONORARY PATHOLOGIST,
CLINICAL DENTAL SCHOOL, LIVERPOOL.

AN apparently healthy lad was anaesthetized with nitrous oxide and the stumps of a molar tooth extracted. He never recovered consciousness and died in thirty-seven hours. The main features of this remarkable case are as follows.

A.B., aged 17, the brother of a dental student of Liverpool University, was seen by a dentist in June, 1923; he unsuccessfully attempted to remove two stumps of a lower molar tooth. A local anesthetic was used. Six months later the jaw was x-rayed at the Liverpool Dental Hospital and an appointment made for extraction. On Saturday, January 26th, 1924, the patient came to the hospital as arranged. At 11 a.m. he was anaesthetized with pure nitrous oxide, and the stumps extracted without difficulty. The administration of the anaesthetic and the extraction took a minute or slightly more.

The patient began to recover from the anaesthetic, but soon went a "nasty colour, then black," and collapsed. As air failed to enter the lungs properly he was placed on the floor and artificial respiration resorted to; 15 minims of ether were injected subcutaneously. A few minutes later Dr. Earlam, a house-surgeon at the Liverpool Royal Infirmary, was summoned. He found that the patient was cyanosed. There was a gag in his mouth; but owing to an unusual deformity of the lower jaw the chin was pressing on the larynx. On removing the gag and pulling the chin forward, breathing became much freer.

At 1.30 the patient appeared to be progressing satisfactorily, but was still drowsy, so he was put to bed in the Royal Infirmary under the care of Dr. Douglas Bigland; the temperature was then

102°, and the pulse 118 (see chart). Soon after admission he had a generalized convulsion, lasting one or two minutes. At 3 p.m. the convulsions recurred for about fifteen minutes with incontinence of urine and faeces; they were so violent and persistent that a strait-jacket was necessary.

The patient was treated with wet packs, and the temperature fell a little, but at midnight it was again 102°; the respirations were 45 (see chart). Lumbar puncture was then performed; the fluid, though under slightly increased pressure, appeared normal, but unfortunately the tube containing it was broken immediately afterwards. Throughout January 27th there were no more convulsions, but the coma persisted and the temperature rose still higher; the respirations were about 50. The breaths smelt strongly of acetone, and the urine was found to contain a large quantity of it, but no sugar, no albumin, and no urobilin. More wet packs were employed, also intravenous salines, insulin, and adrenaline. The skin became a peculiar "yellowish tinge," and the patient died at 12.15 a.m., January 28th, thirty-seven hours after the anaesthesia.

Necropsy.

The post-mortem examination was made fourteen hours later by Dr. Howell Evans, lecturer in pathology, Thompson Yates Laboratory, Liverpool University.

The brain was congested and contained a few punctiform haemorrhages; the membranes were normal. The thymus was big "but not definitely enlarged." The tonsils were not enlarged. The trachea and bronchi were intensely congested; there was no blood and no other foreign body present in them nor in the larynx. The lungs (weight, right 1 lb. 4 oz., left 1 lb. 8 oz.) showed moderately extensive early lobar pneumonia of both bases, especially the left—portions were red and sank in water; the margins were moderately emphysematous. Petechial haemorrhages were present on both pleura, but no fibrin. The heart, stomach, intestines, pancreas, and suprarenal glands were normal. The liver (weight 4 lb.) was congested and soft. The spleen (weight 7 oz.) was dark and softer than normal. The kidneys (weight 6 oz.)

were congested. Some of the mesenteric glands showed caseating tubercle with commencing calcification. The mandible was malformed and underdeveloped, particularly posteriorly; it had no angle, for the ascending and horizontal ramus lay in a practically straight line.

Bacteriological Investigation.

Direct examination at the Thompson Yates Laboratory of the juice of the consolidated portion of the lungs showed many organisms like pneumococci. The colonies of bacteria on a Petri plate culture, using "chocolate" agar* as a medium, were approximately 70 per cent. pneumococci, 25 per cent. *Staphylococcus aureus*, and 5 per cent. streptococci. The presence of pneumococci was also demonstrated by inoculation of lung juice into a mouse; it died in three days and the organism was isolated from the peritoneal fluid. The pneumococcus cultures were bile-soluble, and when tested with type serums proved to belong to Group IV. The streptococcus was non-haemolytic. No bacilli of the influenza group were found, though specially looked for.

Histological Investigation.

Consolidated portion of a lung showed great congestion; the alveoli were more or less completely filled with exudate, which consisted chiefly of red cells; fibrin was scanty; the bronchioles contained many leucocytes. There was no pleurisy. Numerous pneumococci were demonstrated in the alveoli by Gram's stain, but no streptococci or staphylococci.

The polyhedral cells of the liver showed much fatty degeneration, the fat being deposited in small droplets round a central nucleus. The kidney showed marked cloudy swelling, and some congestion.

Examination of the Brain.

Though death was clearly due to fulminating pneumonia, yet, "to make assurance doubly sure," the brain was examined microscopically, to eliminate the possibility of encephalitis or other lesions. This was because the writer once made a *post-mortem* examination on an infant aged 6 months who died unexpectedly thirteen hours after a talipes tenotomy. A big thymus of 27.4 grams suggested status lymphaticus; but a microscopical examination of the brain—normal macroscopically—revealed encephalitis lethargica. Ether was the anaesthetic. (Glynn and Dun, 1923, Case 2.) Nevertheless, a section of A.B.'s cerebral cortex—also examined by Dr. G. A. Watson, pathologist to the Rainhill Mental Hospital—showed neither meningitis nor encephalitis. There was, however, a diminution of Nissl granules in the nerve cells—indicating exhaustion from the fits and toxæmia.

1. The Unusual Virulence of the Pneumonia.

Coroners and even medical men often fail to realize that sudden and unexpected death is not infrequently due to acute bacterial infection; so the cause may be overlooked *post mortem*. Death from pneumococcal pneumonia sometimes occurs in six or seven hours, therefore before the development of lung consolidation, particularly in children and young adults (McGowan and McNeil, 1913; Glynn, 1913; Glynn and Dun, 1923; also Wilson and Glynn, 1926).

A. B. was infected with Group IV pneumococcus. But the mortality of Group IV pneumococcal pneumonia is lower than that of the two other common types; for in 17.6 per cent. of 1,993 English and American adults it was contracted with 22.9 per cent. Type I and 35.2 per cent. Type II (Glynn and Digby, 1923, M.R.C. Special Report No. 79, Table XXIV).

The streptococci found in the sputum most probably did not increase the virulence of the pneumonia because they were non-haemolytic; also because they were present in relatively small numbers—namely, 5 per cent. in culture; besides pneumococci only were found in the lung section.

Glynn and Digby have produced evidence that the streptococci they cultivated from the sputum of 77 per cent. of 92 adults with pneumococcal lobar pneumonia, usually exert "little or no pathogenic effect" and were "confined to the trachea and bronchi" (Table XXXVI, also Table XXXV, pp. 132 and 155). They also cultivated the sputum of 26 adults with pneumococcal lobar pneumonia who eventually died, and found streptococci in 73.1 per cent. and *Staphylococcus aureus* in 7.6 per cent. The relative distribution of the pneumococci, streptococci, and *Staphylococcus aureus* in the positive plate cultures was 70.4, 19.5, and 25 per cent., which is similar to that in A. B.'s sputum—namely, pneumococci 70 per cent., streptococci 5 per cent., and *Staphylococcus aureus* 25 per cent.

The unusual virulence of A. B.'s pneumonia was probably due to the patient's low "resistance," and also to the partial asphyxia from the anaesthetic and from the subsequent respiratory obstruction by the deformed jaw, and lastly to the acidosis. It is interesting that even partial

asphyxia with non-irritating gases may produce severe pulmonary congestion (David, 1912; Yandell Henderson, 1926).

2. The Date of the Onset of the Pneumonia.

The lad's health had been good; but on Thursday evening, January 24th, he complained of headache, and his mother found the temperature "a little over 99°." Next day, however, he appeared to be in normal health, so the temperature was not taken; he played bridge till 2 a.m. On the following morning a friend who met him going to the Dental Hospital for the extraction noticed that he was "very flushed." Probably, therefore, the lad's temperature was up at the time of the anaesthetic, especially as it was 102° three hours later.

Now the incubation period of pneumococcal lobar pneumonia, though short, appears to be two to three days or more (Osler and McCrac, 1907). It would also take at least one to two days for the pneumonic consolidation, found *post mortem*, to develop (Asehoff, 1921). Most probably, therefore, the disease had actually begun before the anaesthesia, and the lungs were in the first or congested stage of the inflammation. The usual initial pleurisy and rigor were absent, otherwise the patient might have realized that he was ill and his chest affected. It is interesting that the initial rigor is less frequent in Group IV pneumococcal lobar pneumonia than in the other two common types—namely, 42.9 per cent., contrasted with 77.8 per cent. Type I and 52.6 per cent. Type II (Special Report No. 79, Table XLIV).

3. The Epileptiform Convulsions.

They probably signified the entrance of many pneumococci into the general circulation. It is well known that acute pneumonia in young children is sometimes ushered in by convulsions; but the lad A. B. was 17. Nevertheless, convulsions occurred in a boy of 15 who died of fulminating pneumonia seven hours after the first symptom (Glynn, 1913, Case 2).

4. The Ketosis.

This was severe and first noticed about 11 a.m. on January 27th. It presumably signified acidosis—confirmed by the fatty degeneration of the liver. The ketosis was not the result of the anaesthetic. It was partly due to starvation; the patient had a light breakfast of tea and toast the day before and no food afterwards, except glucose injections at 1 p.m. and 6 p.m. on January 27th. It was also partly due to the fever and to the toxæmia. Terminal acidosis frequently occurs in dying persons.

5. The Source of the Infecting Organisms was most probably Autogenous.

This is because Group IV pneumococcus is the "type" commonly present in the saliva. Pneumococci were demonstrated in 43.5 per cent. of 485 specimens of saliva; 67.4 per cent. of the positive specimens contained Group IV pneumococcus—some of those containing other types were from pneumonia contacts (Special Report No. 79, Table XX). Non-haemolytic streptococci are invariably present and *Staphylococcus aureus* sometimes present in normal saliva.

SUMMARY.

An apparently healthy lad of 17 was briefly anaesthetized with pure nitrous oxide and two molar stumps extracted without difficulty. But he never recovered consciousness. Three hours later his temperature was 102°; then epileptiform convulsions occurred, and finally acidosis and hyperpyrexia. He died of pneumococcal lobar pneumonia thirty-seven hours after the anaesthetic.

The bases of both lungs showed early red hepatization; the pneumococcus was of Group IV and therefore probably an autogenous infection. Most probably the pneumonia had begun at the time of the anaesthesia, especially as the patient was indisposed two days before.

The virulence of the pneumonia was probably due to the patient's low "resistance" and also to the partial asphyxia from the anaesthetic and the subsequent temporary respiratory obstruction by the deformed jaw, and lastly to the

* Chocolate agar is a mixture of agar and boiled blood; it is especially suitable for growing bacilli of the influenza group (W. Levinthal, *Zeits. f. Bact. u. Infektionskrankh.*, 1919).

But for the *post-mortem* examination, death might have been attributed to an extraordinary susceptibility to nitrous oxide poisoning.

I wish to thank Dr. Douglas Bigland for kindly giving me the notes of the case.

A NEW SYSTEM OF TREATMENT OF DIABETES MELLITUS.

BY

HENRI CHABANIER, M.D., D.Sc. PARIS,

DIRECTOR OF LABORATORIES IN THE FACULTY OF MEDICINE OF PARIS;

AND

W. S. C. COPEMAN, M.B., M.R.C.P. LOND.,

LATELY ASSISTANT ETTRANGER IN THE FACULTY OF MEDICINE OF PARIS.

THE following is an outline account of a method of treatment which, although not claimed as a cure for diabetes, has been employed in over 160 cases of varying degrees of severity with considerable success since 1923.¹

If insulin be administered in large doses before the two principal meals of the day, over unbroken periods, it has been observed that a certain summation of effect can be obtained. That the actual basal trouble is diminished in intensity is shown by the progressive lowering of the "ketonic threshold value"—the point at which ketonuria appears when a patient is placed on a diet containing a known quantity of protein and fat and no carbohydrate. This value is expressed as the patient's blood sugar content at this moment, and is a direct method of expressing the intensity of the basal factor at any given period.

This action of insulin can be pushed to such an extent that the patient may be transformed, metabolically speaking, into a normal person whilst under its influence; this condition being capable, in favourable cases, of persisting for variable periods after the cessation of injections. This experience led to the idea that treatment might be attempted in the form of "series" of injections, somewhat in the same way that syphilitic courses are arranged. The results which have been obtained appear to justify the adoption of this method of treatment, at any rate in a majority of cases.

Advantage is, further, taken of the fact that the patient is temporarily transformed into a normal individual to increase considerably the ingestion of carbohydrate which can, under the influence of the large doses of insulin administered (80 units per twenty-four hours), be easily tolerated and utilized to improve the general condition and resistance of the patient. It is found that in spite of the fact that, in certain instances, the regime is increased to almost normal proportions, the urine becomes sugar-free, and the blood sugar falls to the region of the normal in a short time.

It is considered that every case of diabetes mellitus presents two essential elements: (a) a basal, or metabolic, element; (b) a renal element.² The former consists in the defective power of the tissues to consume glucose in normal ratio to their blood sugar content—for quantitatively this consumption is often found to be equal to the normal. The renal element is a phenomenon similar to that observed in cases of "renal glycosuria," but with the basal element superimposed.

These two elements may be combined in varying proportions, the preponderance, or otherwise, of the renal element tending to determine the clinical type of the disease (*D. gras*, or *D. maigre*). This being so, it is found advisable, when fixing the initial regime of a diabetic patient, to estimate approximately the intensity of this renal factor; since it is found experimentally that in any given case the time taken for the glycosuria to become normal is in inverse ratio to the importance of the renal diabetic

element. This is estimated very simply by comparing the blood sugar of the patient taken whilst fasting with his twenty-four hourly output of urinary sugar. If the difference is considerable, the renal element is said to be pronounced, and the carbohydrate content of the diet is modified somewhat in consequence, in order to allow of the glycosuria becoming normal in a minimum of time. It is seldom, however, found necessary to reduce it below a daily ration of about 100 grams, whilst if the renal element is found to be of moderate importance only, a ration of between 150 and 250 grams may be allowed from the start.

The insulin "series" is then commenced, the injections being given twice a day by the intramuscular route, generally into the buttock, and before the principal meals of the day in which most of the carbohydrate is massed. Hospital out-patients bring with them the 150 grams of milk which is specially introduced into their regime for the purpose, and which they drink immediately after the injection, by this means avoiding the risk of hypoglycaemic accidents which might otherwise intervene before they could reach their homes. Accidents of this nature, it may be mentioned, have been observed in only 7 cases amongst the 50,000 or so injections given between 1923 and 1925.

When the glycosuria has been nil during a minimum period of fifteen days, and if the blood sugar is within reasonable limits, the injections may be suspended, pending a return of the symptoms, which must be carefully watched for; a further "series" being commenced under the same conditions as the former on the slightest indication. In this way the free intervals between the series will be found gradually to increase, whilst the duration of the series can be progressively diminished to a minimum of about ten days, until a patient with a basal trouble of moderate severity, who has come under treatment early, may be enabled to go three months or so at a time without insulin. Longer than this it is not considered advisable to permit the patient to go, although it is occasionally quite possible—two patients, for instance, having actually been able to dispense with insulin for over a year without return of their symptoms. In the intervals between the "cures" the diet is modified merely to the extent necessary to maintain the glycosuria and blood sugar at the same level as they were whilst the patient was receiving insulin.

Indications.

It is considered that every case of diabetes mellitus presents an indication for treatment by insulin, however slight it be. Contrary to the classical conception of insulin as "a useful adjunct to diabetic treatment," insulin is here considered as the factor *par excellence* of the treatment, dietetic methods being only of secondary importance, and never insisted on to the degree which is at present usual; certainly never to the detriment of the patient's general condition.

In states of pre-coma and coma insulin is naturally indicated, although it is not considered to be by any means the best indication from the point of view of ultimate results, since so much damage is frequently sustained by essential viscera, such as the kidney or the heart, during the presence of a state of acidosis, that delayed collapse is frequent even after apparent cure.

In cases of mild diabetes of the type known clinically as "gras" it is considered that insulin treatment should be instituted even when the glycosuria can be controlled, as it generally can, by dietetic methods alone. This is particularly true in the presence of any of the ordinary diabetic complications, such as pruritus or carbuncle. It is in cases of severe diabetes (*maigre*), with acetonuria, that this treatment finds its best indication, if the patients come under observation early,⁴ since in these cases a very real benefit will generally result from repeated "cures," at increasing intervals if this be found to be possible.

Results.

The immediate results of this system of treatment are estimated as the result of observations of (1) the ketonuria, (2) the glycosuria, (3) the general condition of the patient, and (4) his blood sugar content.

1. The effect on the condition of ketonuria, if present, is extremely marked. The ketone bodies of the urine result, it is generally believed, from the incomplete oxidiza-

tion of fatty acids, this incomplete oxidization resulting from (a) the inability of the body to utilize carbohydrate adequately, or (b) an insufficient supply of carbohydrates to enable the body to oxidize the fatty acids completely to their final products (Rübner and Zeller). In the former case the defect of metabolism is remedied by insulin, whilst the latter eventuality does not arise, owing to the high content of carbohydrate in the ration allowed.

2. The glycosuria can, in the average case, and in spite of the large amount of carbohydrate allowed, generally be abolished in a short time, any considerable "renal diabetic element" being compensated for as explained above.

3. The improvement in the general condition of the patient is considered, under this system, to be an even more important criterion of progress than a lowering of the blood sugar content, and is generally very noticeable; the first effect observed being usually a disappearance of the weakness and lassitude so characteristic of the diabetic. If the patient be weighed at the same time every morning the weight will nearly always be found to augment progressively; whilst the suppression of such symptoms as polyuria, polyphagia, and insomnia, together with the possibility of his leading a normally active life, generally has an important psychological as well as physical effect on the patient.

4. The blood sugar will always fall to a level approaching the normal, this being all that is considered absolutely necessary.

Of the remote effects of this treatment less can, naturally, be asserted, although the diabetic process appears in many cases to have been arrested for various periods—as, for example, in the case of the two patients mentioned above who were free from all symptoms for over a year, after several insulin "cures"; such cases, however, form a minority of the whole, the average free period being considerably shorter. Actually no case is allowed to go for more than about three months without receiving insulin, a new series being commenced automatically at the end of that period, whether any direct indication be present or not.

In certain cases, nearly always children, who have come under treatment late, it is found impossible to suspend the injections of insulin at all; these cases can, however, be brought to, and maintained in, a condition in which they can continue their normal lives and activities. The younger the patient the more necessary does it appear to start such a treatment early, and not to waste time on dietetic methods which seem, in most cases, to have little or no effect on the basal dietetic factor, but which merely suppress the symptom of glycosuria, and sometimes that of hyperglycaemia.

Finally, owing to the minimum of restrictions, both dietetic and otherwise, imposed on patients submitting to this regime, it is found to be easier to persuade them to continue on it over long periods than it would appear to be under some other methods of treatment.

A CASE OF PATENT DUCTUS ARTERIOSUS.

BY

WILLIAM GORDON, M.D., F.R.C.P.,

SENIOR PHYSICIAN TO THE ROYAL DEVON AND EXETER HOSPITAL.

THIS case, apart from its rarity, presents several features of interest.

A man, aged 31, a wine-merchant's cellarman since the war, a gymnasium instructor during the war, and a gardener before the war—all occupations involving heavy physical strain—has had gradually increasing shortness of breath for nine years, occasional short attacks of stabbing pain over the heart, mostly at night, for six years, and palpitation caused rather by worry than by exertion. He has never had rheumatic fever, scarlet fever, or syphilis, never had a severe blow on the thorax, never felt anything "give way" in his chest during an effort.

His heart is nearly normal in size, but a little dilated rightwards. The apex beat lies just inside the left mammary line—in the erect position it beats behind the sixth rib, but this is due

to cardiopneumosis, since, in the recumbent posture, it is found, as normally, in the fifth space; but the right margin of its dullness in the erect position is 1½ inches to the right of the mid-line—that is, about an inch too far to the right. There is no excessive impulse anywhere and no thrill. In the second and third left intercostal spaces there can be made out, at least after exertion Gerhardt's "ribbon dullness." There is a loud, roaring, continuous murmur, the entire cardiac cycle, with marked systolic character, the sternum and position. On re-murmur is a movement of its area of maximum loudness about 1½ inches leftwards. The murmur rapidly lessens in loudness as one recedes from this maximum area, except downwards along the left sternal border and the adjoining third, fourth, and fifth spaces. But it is faintly heard over almost the whole chest, front and back. In the area of maximum loudness there is no audible second sound, but lower down, at the levels of the third, fourth, and fifth spaces, there is heard an accentuated and sometimes reduplicated second sound. Over the aortic cartilage and up the right carotid a clear second sound is audible, not reduplicated and nearly free from the continuous distant rumble of the murmur just described. At the sixth left space in the mammary line, in recumbency, the rumble is sometimes quite lost and then a second sound is clearly heard without reduplication or murmur. Fig. 1 shows most of these signs.

The pulse is regular, about 84, rather sudden but not collapsing, and pulsation is certainly more visible than usual in the neck up to the ears and at the elbow. The left pulse is slightly smaller than the right. Here are tracings of both pulses taken with the lowest pressure of a Dudgeon's sphygmograph; they do not suggest aortic regurgitation (Fig. 2). The blood pressure is low—110 systolic and 55 diastolic. The pulsus paradoxus, described by François-Franck,³ is absent in this case.

Fig. 1.—E E=Outline of cardiac dullness in erect position. R R=Outline of cardiac dullness in recumbent position. Shaded area=area of murmur in erect position; unshaded area outside E=area of murmur in recumbent position. + =Spot where the second sound was free of all murmur. O=Spots where the second sound was nearly free of the distant murmur.

Fig. 2.

The respirations are quiet (20), the temperature constantly subnormal (I had him six weeks in hospital), there is no enlargement of spleen or liver, no sign of embolism, no haemorrhage, no daily changes in the murmur. Except for pyorrhoea (which has to be seen to) there is nothing else abnormal in any structure. There is no clubbing of fingers, no polycythaemia, but after exertion there is slight cyanosis of the fingers.

Diagnosis.

The murmur is, as Gibson of Edinburgh² first insisted, pathognomonic of patent ductus arteriosus—that is, a continuous murmur, with systolic augmentation, only dying out in the end of diastole; here I do not lose it at any point of the cardiac cycle. It has received the names of the "tunnel murmur" and the "machinery murmur." It is quite different from any other murmur with which I am acquainted. But it is said to be also produced by the opening of an aortic aneurysm into the pulmonary artery. The history of this case makes that diagnosis unlikely, and the x-ray examination definitely negatives it (Fig. 3).

Patent ductus arteriosus, then, accounts for the murmur. And in support of that diagnosis we find (1) the Gerhardt "ribbon dullness," (2) accentuated and divided second sound lower down, (3) unequal pulses (with, in this instance, low arterial tension, a feature not hitherto noted, I think, but likely to be common in this condition), some enlargement of the right heart, together with x-ray observation of dilatation and unusual pulsation of the pulmonary artery.

But it has been suggested that this might be a case of aortic regurgitation with an unusual dislocation of the murmur, because there is some visible pulsation in the neck. Apart from the facts that the murmur is absolutely different from any produced by aortic regurgitation and that such dislocation of an aortic murmur must be ex-

tremely rare (except in case of transposition of the heart), this idea is negatived by the further facts that the aortic second sound is nearly free from rumble over the aortic cartilage and sometimes quite free from any murmurish sound below the apex in recumbency, whereas there is no second sound at all over the area of maximum murmur.

FIG. 3.

With regard to the visible pulsation in the arteries, I do not know of any reference to it in other cases of this sort. Probably this is due to its usually slight degree. It should be remembered, however, that patent ductus arteriosus is itself a form of aortic leak—not, indeed, into the left ventricle, but into the pulmonary artery—and may, if free, be expected to produce a sufficient difference between the systolic and diastolic pressures to cause visible arterial pulsation. But these pressures would both be probably low as they are here, since the systolic pressure is not reinforced by the contraction of a powerful hypertrophied left ventricle (as is the case in ordinary aortic regurgitation) and the leak is continuous through both systole and diastole.

It may be asked how one can be sure that the divided second sound over the lower spaces is pulmonary. For a full exposition of the reasons I must refer to a previous paper.² The current explanation of the division of the second pulmonary sound in mitral stenosis, or other diseases which increase the pressure in the pulmonary artery, can be easily disproved by mapping out its area of audibility and often by palpating the shock of the closure of the pulmonary cusps, which, like the sound, is reduplicated. The sound is produced by asynchronous closure of the pulmonary cusps themselves. This fact has a real value, as in such a case as this, in distinguishing a second pulmonary from a second aortic sound, because, owing to its thicker walls, the aorta rarely dilates at its orifice sufficiently to put its cusps on the stretch. Unequally-sized cusps when the orifice is stretched must become unequally deep and so cause their fluid of closure asynchronously.

But it might be suggested that the rumble here is really a double murmur due to regurgitation accompanying a congenital pulmonary stenosis. That is excessively rare. Also the rumble does not in the least resemble a double murmur. Further, the maximum of the diastolic murmur would not be in the second space. And lastly, the second pulmonary sound would require explaining; its accentuation and reduplication make any regurgitation there extremely improbable.

Prognosis.

Prognosis is the most important point in the case. Patent ductus arteriosus is the one congenital lesion which ever undergoes spontaneous cure. But that is in early life. Cases which persist into adult life may, however, live to considerable ages; 30 does not appear to be a very unusual age, and Walsham⁴ has recorded a case which died

at 47, and Hale-White⁵ one which died of angina at 53 with a ductus as large as the anterior tibial artery. Other cases at lesser but considerable ages are mentioned in Abbot's able article in Osler and McCrae's *System of Medicine*.⁷ Will this patient live so long? The pulmonary artery tends to become atheromatous under the strain, and sometimes begins to leak, as was clinically followed in Thayer's⁶ case, quoted in Laubry and Pezzi's valuable work on congenital heart disease. Here, as has just been said, there is no evidence of regurgitation.⁸ Some die, as in Hale-White's case, of angina, and here anginoid pains are present. The serious feature, indeed, is that disabling symptoms are already in existence. But the conditions of strain of work have been very bad, and his improvement, since he has rested, is considerable. In any form of congenital heart disease one must never forget the curious special liability to infective endocarditis. We can only hope that, with continued rest (seeing that he looks robust), the existing symptoms may subside.

Treatment.

The treatment has been by rest, at first in bed, now at home, avoiding all strain, good feeding, and, in the way of drugs, small doses of sodium iodide, arsenic, and digitalis, with larger doses of strychnine.

Lastly a word about the effect of change of posture. I have seen four cases of patent ductus. The first was shown by the late Dr. Gibson at a meeting of the Association of Physicians at Edinburgh, when he corroborated the effect I found—namely, that the practically continuous murmur heard in the erect position became definitely discontinuous in recumbency. Another case, seen last May at the London meeting of the same association, showed the same change, which was verified by several present. In the other two cases, this and that of a boy seen in private some years ago, posture made no change in the duration of the murmur. The point is not merely academic, for in recumbency the murmur, if it is discontinuous, is less distinctive and might be mistaken.

I have to thank my colleague, Dr. Miller Muir, for the trouble he has so kindly taken with the x-ray examination, and my house-physician, Dr. Durran, for the pulse tracings.

THE MENTAL CONDITION NINE YEARS AFTER MENINGITIS TREATED BY FREQUENT VENTRICULAR PUNCTURE.

BY

HAZEL H. CHODAK GREGORY, M.D.,
ASSISTANT PHYSICIAN, ROYAL FREE HOSPITAL, LONDON.

THE following is an account of the mental condition of a child who was under my care in the Royal Free Hospital in 1917, suffering from a severe attack of meningitis at the age of 5 months. She recovered, and is now 9 years of age.

The onset, with pyrexia, constipation, and fretfulness, was not recognized as that of cerebro-spinal fever until towards the end of the first week, when the tense fontanelle and staring eyes suggested the diagnosis. Lumbar puncture was then performed and abundant fluid with large numbers of pus cells and meningococci was obtained. Antimeningococcal serum was given intrathecally and puncture was repeated on the second and fourth days. Unfortunately on the fifth day no fluid could be obtained from the spinal canal, and it became necessary to relieve the tension by puncture of the right lateral ventricle through the lateral angle of the fontanelle. During the next three weeks the intracranial pressure remained very high, and the ventricle was punctured almost every day, yielding sometimes as much as 100 c.cm. of fluid; this was partly replaced by small doses of antimeningococcal serum. In all 30 c.cm. of serum were given. After the first few days meningococci ceased to appear in the fluid, which gradually became clearer. As the tension relaxed ventricular puncture was made at longer intervals, and was stopped at the end of five weeks. By this time a fair degree of hydrocephalus was noticeable, the head measuring 17½ inches, but the pyrexia and vomiting had ceased and the general condition was much improved. The only complication was a fluid swelling of the right knee-joint. The infant was sent home in good condition.*

* The case was described in a paper on cerebro-spinal meningitis by Dr. Helen Mackay (*Lancet*, January, 1920).

I saw her again when she was about $3\frac{1}{2}$ years of age; she was a bright little thing, but with an unduly large head, happy, and clean in her habits, though decidedly backward, talking and acting more like a child of 18 months than a normal child of 3.

I did not see her again until last summer, 1925, when she was $8\frac{1}{2}$ years of age. She then appeared well grown, robust, and inclined to be too fat. She had a squint and her vision was obviously defective. Unfortunately she had been taken to an optician and supplied with glasses which were quite incorrect. Hearing was good. The limbs seemed perfectly normal; there were no signs of spasticity or weakness, etc.

Mental Condition at 9 Years.

Beyond observing that she was a great chatterbox, an untrained person might have been in her company for some time without noticing any abnormality. The child evidently enjoyed life very well, had bright eyes and a frequent smile, laughed easily and scarcely ever cried. Her chatter was incessant, but had very little novelty in it, as she constantly repeated herself and would ask the same questions over again, making little attempt to record the answers in her mind. She was immensely inquisitive. She was imitative, and often in speaking to adults would exactly imitate the tone and attitude they adopted towards her. The result was sometimes exceedingly funny. She had a good memory, both for incident and for words and figures learnt by heart, but her reasoning powers were very poor. She evidently disliked having to make the necessary effort to reason, so avoided it as much as possible. When asked an unexpected question she would often turn to someone else for an answer rather than trouble to think it out herself. The same may be said for her powers of concentration; nothing occupied her mind for more than a few minutes. She was an affectionate child, sweet-tempered, and eager to please, but fickle and overtrusting.

Her upbringing had not been on the right lines. She was the eldest of the family, and from an early age had been given all kinds of domestic work to do in the house, including the care of her brothers and sisters. She was willing and able in her household jobs, but unfortunately none of the work called for any exercise of the mind. Her parents' social status was such that the school attendance officer did not step in, and any attempts at education were home-made and spasmodic. Six months ago she had barely mastered the letters of the alphabet. Her mother was affectionate but dominating, and asked for implicit rather than reasoned obedience.

During the last six months the child's mental outlook has definitely improved. She has been living away from her family, among children older than herself, attending a day school and at the same time having the help and individual attention of a good teacher. Her reasoning power is being deliberately stimulated and encouraged. She can now read and write easy words and sentences. She is learning to play games with other children. Music has always been a delight to her, and she is now being taught to play the piano; to this she gives all the power of concentration she possesses, and is evidently going to do well. The error of refraction has been corrected with suitable glasses. I have tested her with some of the intelligence tests. According to Binet's series she has a mental age of about 8, but I consider that these tests have too low a standard and do not require much reasoning power. On the other hand, she gets low marks in Ballard's picture tests for children of 6, obtaining only 35 out of a possible 100 marks. These tests demand considerable powers of accurate observation, and accuracy is not the child's strong point. As a matter of fact, her development has been irregular and therefore not comparable with any particular age. It is not a case of simple retardation—indeed, this rarely is so with mentally deficient children.

The prognosis seems to be very fair. The child will probably never have much depth of character and must always have someone to lean upon. Her chief danger when she passes puberty will be her affectionate trusting nature and her desire to please. The morality of the mentally defective is only on the surface, and the child could easily be led astray. She will, however, be able to carry out all the ordinary duties of a woman's life. Her parents are both exceptionally clever and intellectual people, and there seems no reason why she should not marry and have clever children. She reminds me of the mental condition of a mild case of spastic diplegia, in the tractability of temper, absence of any tendency to viciousness, and good response to treatment. She has an equally hopeful outlook if her education can be continued on sensible lines.

It has seemed worth while to record this case, which occurred at the time that frequent withdrawal of cerebrospinal fluid and daily administration of antitoxic serum were first being practised in the treatment of cerebrospinal meningitis. The case is exceptional—first, in having recovered at all after such an early attack, and secondly, in having suffered comparatively little brain damage in spite of repeated ventricular puncture. There can be little doubt that, if the fluid had been allowed to collect, the resulting hydrocephalus would have produced a hopeless imbecile.

A CASE OF HYDATID CYST OF ORBIT:

REMOVAL OF CYST WITH PRESERVATION OF EYE AND VISION.

BY

E. A. SEALE, M.A., M.D., B.Ch., T.C.D.,
OPHTHALMIC SURGEON, SETTLERS' HOSPITAL.

I TAKE the above title from Mr. J. B. Lawford's paper, read before the Ophthalmological Society of the United Kingdom in December, 1894 (vol. xv of the *Transactions* of the Ophthalmological Society of the United Kingdom)—it so accurately fits the case I now describe. In this paper Mr. Lawford says: "It probably falls to the lot of few men to operate on many cases of orbital hydatid cysts."

A healthy-looking Kaffir girl, aged 8, was sent to me by Dr. J. do Villiers, medical officer of health. Her parents accompanied her, and gave me the following history. About two years ago they noticed an enlargement of the right eye. It gradually increased, without any complaint of pain or discomfort from the child. On inspection the right eye was protruded about half an inch, and also displaced down and outwards; it was limited in its upward and inward movements, and showed a marked external strabismus. The upper lid was puffy and oedematous, mostly to the nasal side, but could cover the eyeball completely. Backward pressure caused no pain, and did not reduce protrusion; nor was the latter perceptibly increased with the head below body level. Tension was normal; no pulsation or bruit present; pupil active and normal, as also were conjunctiva and cornea. Right vision=6/9 (about), left vision=6/6. The ophthalmoscope showed the media clear. The only abnormality was a haziness of the edge of the right disc as compared with that of the left. A swelling of bony hardness was felt about the right trochlea.

On admission to the Settlers' Hospital she was x-rayed by Dr. R. Temple Harrison, who reported a uniform shadow in the right orbit with porosis of bone at the inner side above. The whole right orbit was about three-sixteenths of an inch below the level of the left. On further examination I felt a soft, bag-like mass upward and inward where the swelling was greatest. This could just be grasped by fingers pressed deeply above the lid, but slipped quickly away—a factor I thought definite enough to allow a diagnosis of hydatid, even with absence of the usually associated symptoms.

Under a general anaesthetic an incision 1 inch along the upper orbital margin was made. Cautious dissection disclosed at the inner side a pearly grey, glistening, flaccid structure, closely surrounded by orbital fat, with numerous fibrous attachments. A syringe was ready, and about a teaspoonful of clear watery fluid was withdrawn. Immediate boiling showed it to be albumin-free. So deeply and firmly was the cyst attached to the orbital apex that I feared to go beyond a gentle effort at removal, though I got down fairly close to its origin.

With a small Volkmann's spoon I scraped it out thoroughly. The inner lining came away in pieces like coagulated white of egg. Even after this scraping moderate traction failed to move the sac. I wiped it out freely and firmly with gauze moistened with tincture of iodine, going down to the base, inserted a rubber drain, and sewed up. A small amount of orbital fat was unavoidably lost. The bleeding, though troublesome, was perhaps less than one would expect. Dissection was kept as close to the orbital roof as possible so as to avoid injury to the muscle cone.

I estimate the cystal capacity at about two teaspoonfuls. The sac showed little progress in closing, even with a gradually shortened drain, and, in about three weeks, swelling in the original position, with oedema of the lid, again appeared, and so closely resembled the first picture that I suspected a similar cause. However, on opening up again, I could find nothing but the old sac, which, I concluded, had become obstructed and distended. This time I removed it thoroughly, though to do so meant much more disturbance to the orbital apex than on the first occasion. The muscle origins of the superior rectus, and levator palpebrae superioris from the annulus of Zinn surrounding the optic foramen, with their nerve (oculomotor), within the annulus, could hardly escape injury when the implantation area was dealt with.

A skiagram taken two weeks after the first operation with a probe passed to the cyst bottom showed the point very close to the optic foramen.

Between the first and second operations I had the advantage of reading Mr. D. J. Wood's paper in the *British Journal of Ophthalmology* (January, 1925). Here he described three cases of orbital hydatid which he had seen during the last few years. This experience, judging by the literature on the subject, must be unique, for authorities are agreed as to the comparative rarity of the condition.

Microscopic examination of the scrapings showed the presence of hooklets. I am indebted to the Department of the Director of Veterinary Research, Pretoria, for the report that the parasite was apparently *Echinococcus granulosus*.

The condition of the patient four months after operation was as follows: Right vision=6/6. General health excellent; no squint; occasionally fixation (binocular) is not well maintained, and a slight outward deviation can be detected. She has no discomfort, and admits to no diplopia. Proptosis, though much less, persists, and the eye, as before, is on a lower level than the other; in fact, owing to orbital asymmetry, its position has been little altered by the operation.

All ocular movements are good and free, except up and in; here the horizontal level is barely exceeded. An unfortunate feature is paresis of the levator palpebrae superioris. This I attribute either to injury of the superior division of the third nerve—which supplies both levator and superior rectus muscles—or to trauma of their combined tendinous origin in the apex, done, no doubt, during the second operation, when the implantation area was removed. However, within the last week or so I have noted with pleasure a distinct improvement in levator function. The hard swelling in the trochlea region persists.

Points of interest in the case were:

1. Absence of pain and head symptoms.
2. Flaccidity of cyst; reported cases usually tense.
3. Presence of hooklets. "Presence of heads and hooklets is noted in only a small minority of cases of human echinococci."—(Leuckart's *Parasites of Man*.)
4. The marked orbital asymmetry—congenital, no doubt.

LITERATURE.

Trans. Ophth. Soc. of United Kingdom, vols. xv (Lawford), xvii (Hill Griffith), and xxiii (Werner).

Casey Wood in his *System of Ophthalmic Operations*, p. 853 et seq. summarizes the literature of the subject and mentions that up to 1910 over a hundred cases had been reported.

ABDOMINAL CASES ILLUSTRATING IMPORTANT SURGICAL PRINCIPLES.*

BY

J. LIONEL STRETTON,

CONSULTING SURGEON (WITH CHARGE OF BEDS), KIDDERMINSTER AND
DISTRICT GENERAL HOSPITAL.

The following four cases considered together illustrate different conditions, and convey valuable surgical lessons.

CASE I.—Rupture of Spleen.

A woman, aged 37, was seized with violent pain in the left side of the abdomen and chest after getting out of bed to pass urine at 8 a.m. on March 22nd. The pain shot down to the upper part of the left leg. When seen by Dr. Dykes at 9 a.m. she was so collapsed that he would not sanction her removal to the hospital. Later in the day she improved sufficiently to be sent there, and arrived between 3 and 4 p.m. On admission she was very blanched and restless. Her pulse could not be felt at the wrist; her heart sounds were very feeble, and 150 to the minute. The temperature was subnormal, the abdomen painful and tender. The uterus reached up to the umbilicus, and other signs of pregnancy were present. She had not menstruated since October. There had been no haemorrhage from the vagina. A tentative diagnosis of ectopic pregnancy had been made, with which I did not agree. She was suffering from intraperitoneal haemorrhage.

She was immediately taken to the theatre and the abdomen was opened by a right paramedian incision 6 inches long, starting just above the umbilicus. When the peritoneal cavity was opened it was found to contain about 4 pints of blood and clots. The uterus was intact, the tubes and ovaries were normal. No bleeding point could be discovered in the omentum or the mesentery. Both kidneys and the liver were normal. On further examination a bleb about 2 inches in diameter was found on the spleen near the splenic notch, and blood was issuing from an aperture in this bleb about the size of a No. 1 catheter.

The spleen was removed, the blood and clots were sponged out, and the wound was closed in layers. A pint of normal saline solution was infused. The patient gradually improved and, except for an acute attack of parotitis, made an uninterrupted recovery.

On examination of the spleen after the operation a tear 1½ inches long was found under the bleb. It is difficult to account for the rupture of a spleen that appeared to be normal. A portion of the organ was submitted to the pathologist for examination and he reported it normal.

There was no history of any injury, and I cannot conceive that the act of getting out of bed to pass urine would cause the rupture. When I thought the matter over it occurred to me as possible that the rupture might have been due to excessive violence during the act of coition. The woman had gone as house-keeper to a very strong, virile man, and she was apparently five months pregnant. I interviewed the man, and ascertained that coition did take place that morning between 5 and 6 o'clock. I think it is more than possible that the rupture of the spleen occurred at that time. The bleeding was under the capsule of the spleen and the action of getting out of bed caused the bleb to burst.

CASE II.—Perforated Gangrenous Appendix.

A man, aged 50, was seized with violent pain in the epigastrium at 5 p.m. on March 15th. When Dr. Robinson saw him he was so collapsed that it was not thought wise to send him to the hospital. Later in the evening his condition had improved sufficiently to render his removal justifiable. He arrived at the hospital about 9.30 p.m. He stated that the pain had come on without any warning, and that he had vomited frequently since it began. The abdomen was immobile and rigid all over. His pulse was 72, temperature 96°. The diagnosis was perforation of the stomach or duodenum. When I saw the patient the rigidity appeared to me to be more marked to the right of and below the level of the umbilicus, and I expressed the opinion that the perforation was in the appendix. I performed an operation immediately. When the abdomen was opened cloudy fluid escaped. There were numerous old adhesions binding the appendix down behind the caecum. The appendix was gangrenous with a perforation at its tip. The abdominal cavity was mopped out and drainage tubes were inserted. While sewing up the abdomen I remarked to the house-surgeon that there might be a perforation of the stomach or duodenum as well as of the appendix (I believe one or two instances of this are on record), but it was such a very remote possibility that I did not consider a further exploration justifiable, as it might cause the patient's death. He made an uninterrupted recovery.

CASE III.—Obstruction of Intestine by a Band.

A woman, aged 45, upon whom I had operated twelve years before for tuberculous peritonitis, was sent into the hospital on the evening of December 17th, 1925. For twelve months she had been suffering from pains in the abdomen and loss of flesh, and for the past four days from diarrhoea and vomiting; the vomiting had increased considerably in the last twenty-four hours.

The abdomen was found to be distended and rigid. The condition had been tentatively diagnosed as a recurrence of the tuberculous peritonitis. I did not agree with this diagnosis, and expressed the opinion that it was probably an obstruction of the small intestine due to a band. On opening the abdomen I immediately found a band, which partially obstructed the small intestine. But the gut was not extremely distended immediately above this band, and consequently I felt that there must be another constriction higher up. On tracing the intestine I found another constriction, by which the bowel was completely obstructed. This constriction was divided, and the patient made an uninterrupted recovery. If I had not continued my exploration she would certainly have died.

CASE IV.—Abdominal Haemorrhage probably due to Rupture of Omental Vessel.

In June, 1925, I operated for Dr. Smeeton Johnson upon a boy, aged 10, who was suffering from the effects of an accident. The abdomen was full of blood, but I was unable to discover where the bleeding came from. Before closing the abdomen a drainage tube was inserted into the peritoneal cavity. I thought the haemorrhage was probably due to the rupture of a vessel in the omentum, which had become sealed. This supposition was strengthened by the fact that there was no more bleeding, and the boy recovered. I had had a similar case in a man many years before.

Case I illustrates the necessity of exploring every possible source of a haemorrhage found in the abdomen, and of dealing adequately with it if it is discovered. To plug the region of the supposed source of a haemorrhage with packing is not surgery. When the source has been found and controlled the abdomen must be sewn up.

Case II illustrates the reverse procedure. When a perforated organ is found in an acute abdominal case it is not right to seek for another lesion, although there is a possibility that it might exist. The further exploration might cause the death of the patient; it is certain that a surgeon who regularly adopted such tactics would have a very high rate of mortality.

Case III illustrates the supplementary truth that even in an acute abdominal case the surgeon must not desist from his efforts until he is satisfied that he has found the root cause of the trouble.

Case IV illustrates the fact that though the cause of haemorrhage into the abdominal cavity must always be looked for, cases do sometimes occur in which it is not possible to find it. In these cases a tube should be inserted into the peritoneal cavity to give immediate warning should any further bleeding occur.

* These cases were described at a meeting of the Kidderminster Medical Society on Friday, April 8th, 1926.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

PERNICIOUS ANAEMIA FOLLOWING INTESTINAL OBSTRUCTION DUE TO STASIS.

IN March, 1922, one of us (C. L. G. C.) reported in the *BRITISH MEDICAL JOURNAL* (March 4th, p. 347) a case of obstruction, due to stasis, with the following particulars.

"A. B., a woman aged 55, was under . . . care . . . for five months suffering from vomiting [commencing April, 1921]. This occurred two or three times during the day; it had no relation to meals and no distinctive features. She had no pain; the pulse and temperature were normal, and the tongue was clean. She was thin and very sallow. The examination of the abdomen was negative. Constipation was a salient symptom throughout, and aperients were continually required. Dieting and rest in bed for two months relieved her condition so that she was able to go about. She, however, vomited occasionally, and retained a very sallow colour. Generally she had lost weight.

"During August her condition became much worse. On the 25th there was very frequent vomiting, a rising pulse rate, and the abdomen was slightly distended. The next morning the vomiting had become continuous, the abdominal distension was much more marked, and there was very marked peristalsis. Dr. Denyer, physician to Hull Royal Infirmary, agreed that she had intestinal obstruction, and that immediate operation was necessary.

"I opened the abdomen the same evening, and found all the colon immensely distended, but there was no obstruction in the rectum nor any part of the colon. Examination for other causes proved negative. The central incision was closed and a temporary colostomy made. The vomiting stopped immediately, and she has never vomited since. Full-sized motions were passed by the rectum after the fifth day, and some faeces through the colostomy wound. The sallow colour has disappeared. She has gained weight, and is obviously in better health than she has been for years. The weight, which at the operation was 5 st. 10 lb., was 7 st. 1 lb. on February 18th [1922].

"The case seems to fall into the group of cases of intestinal atony following stasis and bacterial toxæmia, well described in Nothnagel's *Encyclopædia*."

Subsequent History.

She remained well until August, 1923, when she consulted us again because of "shortness of breath." She was then intensely anaemic and lemon-tinted, and had occasional vomiting of bile. The colostomy wound was closed, excepting for a minute hole, which allowed a small quantity of liquid faeces to be discharged after aperients had been taken.

The blood was examined, with the following report (date August, 1923): White blood corpuscles 3,000 per c.mm. Blood films: great poikilocytosis with numerous megalocytes; microcytes also seen. Megaloblasts and normoblasts common. Polychromasia and basophil stippling frequently seen. A typical pernicious blood picture.

Two months ago (December, 1925) she again came under our care, when we found her bedridden, very breathless, and, if possible, still more anaemic and lemon-tinted than before. We again had a blood test, as follows: White corpuscles 3,000 per c.mm. Red corpuscles 22,000,000 per c.mm. Haemoglobin 40 per cent. Colour index 1.1; colour of serum, golden yellow. Blood film: poikilocytosis very marked; anisocytosis; many microcytes. Anisochromia marked, polychromasia and basophil stippling; few megaloblasts and normoblasts. Typical pernicious anaemia.

There was never any discharge from ear, nose, or vagina, and all teeth had been extracted fifteen years before the present illness. Nothing has been done for the patient, as she refuses all treatment.

The case seems to show direct association of stasis with bacterial or chemical toxæmia, and subsequent development of pernicious anaemia. The absence of any malignancy is shown by the operation, the five years' duration, and the blood pictures. The intestinal obstruction was due to chemical or bacterial toxæmia, and certainly not to any mechanical means; and, although the obstruction was relieved by the operation, yet the toxæmia still persisted to produce the pernicious anaemia.

RELATIONSHIP OF HERPES ZOSTER AND CHICKEN-POX.

WE are at present attending a female child, aged 8 months, suffering from typical chicken-pox and herpes. The herpetic rash was most marked in the intercostal spaces on the left side of the chest and on the posterior aspect of the thigh. A brother (aged 6) and a sister (aged 4) were recovering from chicken-pox, and the mother stated that when seven months pregnant with the last child she suffered for a month from shingles, and was in hospital for that period.

Numerous cases have been reported of a child developing herpes a few weeks after other members of the family had had chicken-pox; but we believe this is the first reported case in which both rashes appeared at the same time.

W. H. SMITH, M.B., Ch.B.
Birmingham.

SOME ten years ago I published a case which I considered undoubtedly to prove some connexion between herpes zoster and varicella, and have, of course, seen many similar instances in the *JOURNAL* since. Here is another.

On April 3rd last I saw an elderly woman who was suffering from a very severe attack of herpes zoster. Sixteen days later an only grandchild, aged 4, living in the same room, developed a profuse rash of varicella. No source of infection, other than from the grandmother, could be traced.

HOWARD DISTIN, M.B.

PULMONARY TUBERCULOSIS IN OLD AGE.

IN the *JOURNAL* of December 26th, 1925 (p. 1223), Dr. A. P. Ford describes the case of a patient who developed pulmonary tuberculosis at the age of 77.

I have recently seen a woman who had good health until she was 65 years of age, when she developed pulmonary tuberculosis and died within six months. A few weeks before she contracted the disease her sister, whom she had been nursing, died of consumption. She knew of no history of tuberculosis in her father's or mother's families, but two of her brothers and four sisters had died of consumption at the following ages: 30, 44, 76, 78, and 81.

London, W.1.

L. S. T. BURRELL.

SEPTIC SORE THROAT COMPLICATED BY ERYTHEMA NODOSUM.

A SERIES of cases of ulcerative tonsillitis with unusual sequelae has been observed amongst the staff and women patients of the Lingfield Colony. Thirteen cases of tonsillitis with more or less severe pyrexia and an unusual amount of exudation occurred in quick succession, the incubation period being apparently only a few days. An unusual symptom which occurred in five of the cases, and appeared on the third or fourth day of the illness, has been an eruption of erythema nodosum over the front of both legs. Scattered papules were first observed, many of which coalesced, forming large raised irritable patches. Oedema was sometimes present. The erythema lasted a week or more and on fading left a brown stain. Most of the cases had enlarged glands in the posterior triangle of the neck. One case (with erythema nodosum) had a mass of enlarged glands in the supraclavicular region which threatened suppuration, but finally resolved slowly. Two of the cases (not showing erythema nodosum) developed a transient rash on the trunk and limbs, and one of these, a girl who had previously been known to have a systolic murmur at the apex, suffered from precordial pain, rapid pulse, and a soft double systolic murmur which led one to fear the onset of infective endocarditis. She has, however, after three weeks' illness made a fair recovery.

Examinations were made from swabs from several of the throats, but the Klebs-Loeffler bacillus was not found. Cultures have been made from three of the swabs. The bacteriological report was to the following effect:

"Strains from Cases 1 and 11 would be classed as the *Streptococcus anginosus* of septic sore throat and scarlet fever; and the strain from Case 11 as *Streptococcus salivarius*. The only difference between the two is the ability, present in the first type, to develop haemolysin."

Cases of tonsillitis, of only moderate severity, have occurred at intervals in the children's homes during the past few months. Three months ago a boy was removed to the local fever hospital suffering from an apparently typical attack of scarlet fever, but no second case was observed. Can any light be thrown on the diagnosis?

I am indebted to Dr. J. Tylor Fox, the superintendent of the Colony for Epileptics, Lingfield, for permission to make this report.

Reports of Societies.

HUMAN PROTOZOA.

At a meeting of the Section of Tropical Diseases and Parasitology of the Royal Society of Medicine held on May 13th, with the President, Sir WILLIAM PROUT, in the chair, Professor R. W. HEGNER, Professor of Protozoology in the School of Hygiene and Public Health of the Johns Hopkins University, Baltimore, gave an address on the biology of host-parasite relationships among the human protozoa.

Professor Hegner said that at the present time protozoology was for the most part being investigated by zoologists, who were primarily interested in the parasite, and by medical men, who were interested mainly in the host. A programme had been arranged which attempted to bring these two points of view together. The events that occurred during the course of an infection were considered in the following order: (1) Transmission from host to host was brought about by the behaviour of the host or intermediate host and not by the action of the parasite. (2) The distribution and localization of protozoa within a host, including both primary and secondary sites (for example, entamoeba carried through the digestive tract of the host, and by the blood stream to other organs), were largely due to the activity of the host. (3) The host offered a certain degree of passive (natural) resistance to the invasion of the protozoan, and the protozoan likewise resisted the defences of the host. (4) Changes in the host caused by the parasite brought about symptoms and caused pathological changes in the tissues and the building up of active (acquired) resistance. While the symptoms were well known, the cause of these symptoms was obscure and little was yet understood about the resistance. (5) Residence in the host likewise modified the parasite, which might also build up an active resistance and might change in its degree of aggressivity. (6) Host-parasite adjustments occurred during an infection, resulting in latency, the carrier condition, and relapse. (7) The host might be aided in its resistance to the protozoan by biological and chemical therapy and hindered in various ways. (8) The method of escape from the host determined the maintenance of the races of parasitic protozoa. (9) Host-parasite specificity involved the study of host susceptibility and parasite infectivity. (10) Protection from parasitic infections might be afforded to individuals (personal hygiene) and to communities (public health) on the basis of a thorough knowledge of the biology of host-parasite relationships. The programme, as outlined, had been primarily designed for the study of the human protozoa, but might be used as well for other parasites.

Professor R. T. LEIPER congratulated Professor Hegner on his very stimulating and suggestive address. The suggested programme, of course, was based upon the protozoa, but it contained many points of interest to the helminthologist. The helminths were a very different group of animals and much more active in their migration behaviour than were the protozoa; the scheme, therefore, could not be applied in its entirety to the worms, but many of its points were of great importance to the other branches of parasitology.

Professor HEGNER, in a brief reply, agreed that the helminths were more active migrants than the protozoa.

In a paper on some aspects of therapeutic malaria, Dr. G. DE M. RUDOLF said that benign tertian malaria was generally used for the artificial inoculation against general paralysis of the insane instead of the malignant form, which was not only more dangerous but often was not effective. The period of incubation in these cases was related not only to the method of injection but also to the number of parasites injected. Various factors affecting the course of the malaria were discussed. A natural immunity was found in some cases. Atmospheric conditions might affect the malaria treatment. Dr. Rudolf then demonstrated the alterations and deviations from the normal temperature chart of malaria which he had found in patients with general paralysis of the insane. The treatment gave very successful results, especially in

patients in whom the disease was not of long standing. His own results indicated that about 60 per cent. of the patients with the disease of less than eighteen months' standing were discharged, while only 8 per cent. of those who had had the disease for a longer period were successfully treated; on the average nearly 40 per cent. of all cases were discharged.

DIATHERMY IN THE TREATMENT OF PNEUMONIA.

At a meeting of the Section of Electro-Therapeutics of the Royal Society of Medicine on May 21st, Dr. H. EATON STEWART of New Haven, U.S.A., an officer in the United States Navy, gave an address on diathermy in pneumonia. Dr. ALASTAIR MACGREGOR presided.

Dr. Eaton Stewart said that he was unaware that any work had been done on the subject when he started his own in 1921, though he discovered later that as far back as 1906 two American workers had experimented along this line. In 1921, at the Marine Hospital in New York, during an epidemic of pneumonia, it was determined to make an experimental trial of diathermy. The experiment was delayed until a case arrived which appeared to have otherwise no possible chance of recovery. This case, that of a merchant seaman, was believed to be hopeless, and diathermy was given, 2,000 milliamperes for twenty minutes, through the chest, front and back. The clinical improvement was immediate, and the man made an uninterrupted recovery. It was recognized, however, that this might have been an accidental success, and in order to make a study of scientific value a systematic plan was followed for checking the results, and every third case was used as a control. Of 41 cases treated by diathermy in that first series 17 per cent. died, and the results in general were so favourable that they led to a trial of diathermy by a number of workers, who also found that the reduction in mortality compared with the average in similar cases was most definite. The technique varied very little from the first. The electrodes used were of flexible enamel, covered with heavy shaving-soap lather, and were placed directly on the skin. In the treatment of a single lobe in an adult electrodes of 5 in. by 7 in. were usual, and for two adjacent lobes the size might be 6 in. by 8 in. Flexible electrodes of German silver in the form of chain metal had been used, and had the advantage of adapting themselves to the irregular shape of the chest, but there were certain practical disadvantages attending their use. Experience had also shown the value of using a lower milliamperage than had been thought suitable at first, and the tendency was towards quite small amounts of current. A very usual application was 1,200 to 1,400 ma for thirty or forty minutes. The frequency of application in hospital cases was limited by the exigencies of the institution, and in the cases which formed the subject of the earlier reports two treatments daily were the maximum that could be given; but in private practice severe cases were treated every four hours. In desperate cases the intensity of the current and the duration and frequency of application were all increased. An impression had gained ground that it was advantageous to have the cardiac area included in the current pathway, even when that area was not affected, and this was borne out by his own experience. The reports so far collected related to between 300 and 400 cases, a sufficient number to justify an answer being given to certain questions, though not sufficient for dogmatic statements. A remarkable fact was that in about 97 per cent. of the cases treated the temperature had dropped by lysis. In many cases the temperature began to fall as early as the second or third day. A lessening of cyanosis when this was present had been an almost invariable accompaniment of the treatment. The pulse rate fell slightly as a rule. The respiratory rate was lessened on an average about five a minute, owing to the decreased pain and the increased pulmonary circulation. Perspiration was considerably increased, and this, when not too profuse, probably helped matters by toxic elimination. The deep heat produced by diathermy hastened resolution. In any statements on mortality it was necessary to be very conservative, because the disease was one in which the

death rate in different epidemics varied widely. In the cases under review, however, it could be said that the death rate had been about halved. This average death rate of 12.9 per cent. was based upon a total number of cases which represented all types of the disease, including streptococcal lobar pneumonia, and occurring at all seasons of the year. No cases, not even those which were moribund, had been refused treatment, and every case which survived to receive a second application was included in the figures. Of the cases in which diathermy was applied before the third day there were only two deaths in the entire series.

Dr. E. P. CUMBERBATCH said that during a recent visit to the United States he had asked each clinician whom he met what he thought of this treatment, and he found a high opinion entertained with regard to it in every instance. He had not come across one clinician who doubted its efficacy. He added that although there had been earlier workers on the subject, even in the United States, the treatment of lobar pneumonia by electrotherapeutic means would always be associated with the name of Dr. Eaton Stewart.

Dr. W. J. TURRELL, who thought that the chief value of Dr. Eaton Stewart's work was that he had carried this method over from the region of the theoretical to that of the practical, said that there had been a great reluctance on the part of clinicians to take up the treatment in this country. One obstacle to the adoption of the method here was the lack of a suitable portable apparatus. A feature of the cases chronicled which was surprising was that 97 per cent. of them should terminate by lysis.

Dr. C. B. HEALD spoke of a number of cases—one of acute lobar pneumonia, two of delayed resolution, and four of bronchopneumonia—in which he had seen quite definite results follow this treatment. The first case he had ever treated, and one which gave him confidence, was the case of a small child, breathless with bronchopneumonia, upon whom the effect of the treatment was at once most beneficial. A feature to be noted about the improvement which followed diathermic applications was an alteration in the type of breathing; the inspiration, instead of being, so to speak, vertical and dropping sharply, spread out and became longer. He also mentioned the relief of embarrassment and the restful sleep induced. He regarded this as a genuine form of treatment which could be fearlessly given.

Dr. G. B. BATTEN said that Dr. Cumberbatch, after his recent visit to the States, reported that in America the open spark-gap type of diathermy instrument was commonly used. The speaker wondered whether there was any real difference in the resulting current, apart from convenience in instrumentation, as between the open and closed spark-gap. With regard to the effect of heat applied to the chest, some years ago he had occasion to make a *post-mortem* examination of a patient who had had pneumonia, and he found that the effect of a mustard poultice which had been applied had extended to over one inch depth in the chest wall. The administration of deep heat, therefore, seemed to be entirely rational.

Dr. EATON STEWART, replying on the discussion, said that in the States there were several types of portable apparatus. Three or four reliable machines were procurable for about 250 dollars each. Most of these machines were made for currents of 75, 110, and 220 volts. The American Medical Association had lately formed a committee on physiotherapeutics with the object of standardizing the various factors of voltage and frequency, and it was hoped to arrive at a good deal of definite knowledge as a result of its work. As between the open and the closed spark-gap *per se* he did not think there was much to choose. He was glad to find that the value of this treatment in pneumonia was readily recognized in this country. The very large percentage of cases in which there was a fall by lysis was certainly remarkable, and the fall by lysis was a factor in early recovery and increased vitality. In the series of 300 or 400 cases there had been only eleven or so in which the fall had been by crisis or semicrisis. Five or six of the large hospitals in New York were now using this treatment in a routine way, and it was no longer regarded as in the experimental stage.

Reviews.

AVIATION MEDICINE.

MAJOR L. H. BAUER of the United States Army Medical Corps has compiled an excellent textbook, entitled *Aviation Medicine*,¹ for the use of flight surgeons of the U.S. Army Air Service.

He gives a detailed account of the methods used in selecting pilots, discusses the physiology of aviation stress, and in the third section gives advice on the care of flying personnel and prevention of accidents. The book is well illustrated, and the extensive references to the investigations of British, French, Italian, and American workers will make it valuable to all medical men concerned with aviation.

The American methods in selecting pilots are briefly as follows:

Organic diseases are excluded, vasomotor instability is tested by a composite test called "the circulatory efficiency test," which is a combination of the ordinary exercise tolerance test and the difference between the systolic blood pressure taken standing and reclining. Marks are given for satisfactory pulse rates and for a normal rise in blood pressure when the subject assumes the erect position. The total score of marks varies from a maximum of 18 to a minimum of -11.

The pilot is classified as regards ability to fly at altitudes, by causing him to rebreathe into a spirometer until he shows signs of distress. By estimating the percentage of oxygen in the spirometer it is possible to eliminate individuals who are sensitive to lack of oxygen. This test, the author states, takes the better part of an hour to carry out, and during half of the time, whilst the pulse, blood pressure, nervous system, respirations, and mental state are being tested, it necessitates a personnel of at least four attendants and medical examiners.

Vision is tested for acuity and refractive errors, colour perception, field of vision, and accommodation. Judgement of distance is tested by estimating the relative position of two vertical rods at a distance of 20 feet. Ocular muscle balance is also tested by the Maddox rod test. Convergence power and accommodation are also estimated, but no reference is made to any test for neglect or suppression of vision due to fatigue. The description of the examination of the nose, throat, and ear is interesting because of the full account given of the Bárány rotating chair test. The author states that in his opinion equilibrium in the air is a function of the whole proprioceptive mechanism, and that it is very questionable whether reliance can be placed on the Bárány tests in an experienced aviator. "The whole subject," he says, "has been unduly stressed in proportion to its relative value in aviation." Stability of the nervous system is regarded as exceedingly important. Not only is a thorough neurological examination made, but a personality study of the candidate's temperament is carefully carried out.

The section on the physiology of flying deals with the effect of oxygen want at altitudes, and of cold, wind, and speed. Major Bauer refers to the Pulitzer race of 1922-23, when the winners stated that they became dazed or temporarily unconscious when turning at high speed (243 to 266 miles an hour), and regards cerebral anaemia due to centrifugal force as the cause.

The question of fatigue and staleness of the pilot are considered in the last section, where references are made to the investigations of Birley, Flack, and Bowdler in the reports of the Medical Research Council (Air Medical Investigation Committee) in 1918.

Major Bauer describes a condition of neuro-circulatory asthenia, or "effort syndrome," with symptoms of loss of interest in work, constant fatigue, distress on slight exertion, poor muscular control, nervousness, inattention, and carelessness. He attributes it to excessive flying, high altitudes, and war stress, and states that it is accompanied by deterioration in flying ability, particularly in landing. Physical signs are present in the form of increased heart rate, exaggerated response to exercise, and exaggerated responses of blood pressure. Reflexes are increased and coarse tremors of hands are noted. This condition of staleness may be prevented by suitable means, and the author concludes by giving some useful advice to flight surgeons with regard to keeping their pilots in good physical condition.

¹ *Aviation Medicine*. By Louis Hopewell Bauer, A.B., M.D. Published by authority of the Surgeon-General, Baltimore: The Williams and Wilkins Company; London: Baillière, Tindall and Cox. 1926. (Med. Soc. pp. xv + 241; 35 plates. 3s. net.)

PUBLIC HEALTH LAW IN THE UNITED STATES.

THE international health work of the League of Nations, and the series of interchanges of visits of public health officers between country and country, is proving of real value in widening knowledge of disease prevention and health promotion throughout the civilized world. But conducted group visits of brief duration are much the better if supplemented by subsequent study relating to the country visited. Regarding the United States especially, with its enormous territory, its great population, and its numerous States, each self-governing yet related to a Federal Government performing important functions for the whole vast area, the student of public health is especially in need of assistance if he is to form a true conception of the scheme as a whole. Incidentally such guidance is admirably afforded by an important work that has lately reached this country from America.² The author, Dr. JAMES A. TOBEY, is qualified both in medicine and in law, and the volume has a preface by an authority, Dr. Charles V. Chapin, whose name is well known over here. The work, which relates wholly to the United States, is not a student's grind book for examinations, and is not burdened with details of individual Acts or sections, whether State or Federal. It claims to be an exposition of fundamental legal principles applicable to public health procedure, and the claim is justified. The Earl of Derby is quoted approvingly as having declared that "sanitary instruction is even more important than sanitary legislation," and Dr. Chapin agrees with the author that "only matters, which it is intended to enforce should be placed in a local sanitary code, and then these should be enforced and not be permitted to become decorative only."

Differences in the point of view as between England and America naturally crop up in the course of the volume. The author thinks it an unnecessarily narrow restriction to require that a health officer should have a qualification in medicine. "An individual with a Dr.P.H. granted by a first-class school of public health is for that matter much more logically trained to administer a health department than is a physician with no public health experience or training." But these last words beg the question. The sound position, surely, is that a medical degree or diploma should be the foundation on which specialization and a diploma in public health are built, as in the case of other specializations, including osteopathy, which has lately been under incidental reference in the press of the old country.

Dr. Tobey's work is well designed and well arranged. The American plan of government, executive, legislature, and judiciary, is explained, also the Federal constitution and the State constitution. The chief feature is that government is based on definite written constitutions, not as in England, which has no written constitution. A chapter is devoted to the police power and its application to public health, a point being made that, before the constitution of the United States was adopted, individual States possessed the power of health protection. Local health departments are formed for county, city, town, and village areas within a State, and have appropriate powers and duties. Special powers include school hygiene, vaccination, and control of milk, foods, and drugs. The control of communicable diseases is under State laws and local regulations. Under "social hygiene" venereal disease in relation to ophthalmia neonatorum, quarantine, marriage, the repression of prostitution, are discussed, and the functions of "moral courts" are explained. Mental hygiene has a chapter to itself, dealing, *inter alia*, with definitions of insanity, administrative control, guardianship, crime and mental disorders, examination of prisoners, juvenile courts, irresponsibility, the sterilization of prisoners, and the immigration laws in relation to the mentally defective. In a chapter on health officers and employees, a scale of minimum salaries for full-time qualified officers begins with 2,500 dollars (say £500) a year for populations under 10,000, and rises to 10,000 dollars (£2,000) for populations of a million and a half and upwards. Security of tenure does not seem to be so

well guarded as for whole-time officers in this country. Another chapter is devoted to discussion of liability and legal responsibility for injury or damage arising out of public health activities of corporations, health officers, physicians, schools, etc. Various cases are given in illustration of the findings of the courts. The drafting of health legislation and the enforcement of the law has each a chapter to itself. Then follows a very convenient concluding chapter of summary and comment, constituting a useful synopsis of the book as a whole. Finally comes a series of four appendixes, the first of them being a complete copy of the written constitution of the United States, with amendments. Also a long table is given of cases decided in the various courts of the United States. The index is in two divisions—individuals and subjects.

It will be gathered from this account that the work contains a mass of information which, though not relating to this country, may be useful both to health authorities and their officers, as showing the lines which are being followed in the great republic in respect of matters which are being dealt with in one fashion or another by every civilized country in the world.

REPRODUCTION IN THE RABBIT.

MR. JOHN HAMMOND's book *Reproduction in the Rabbit*³ is issued in the series of Biological Monographs and Manuals edited by Dr. Crew and Mr. Cutler. Professor MARSHALL has written a foreword, and also a chapter on the formation of the corpus luteum.

The book deals with many matters relating to the physiology of reproduction in the rabbit. The question which may have chief interest from the point of view of human physiology is probably the relation between ovulation and sexual intercourse. It is well known that in the majority of mammals ovulation takes place spontaneously, and whether copulation occurs or not: but in some species, such as the rabbit and the ferret, the Graafian follicles do not rupture and discharge their ova without the stimulus set up by sexual intercourse. In the rabbit, however, pseudo-pregnancy may be induced under experimental conditions, as by allowing copulation with a male rendered sterile by vasectomy: when this happens ovulation takes place, succeeded by the formation of corpora lutea, and the consequent growth changes occur in the uterus and mammary glands. Mr. Hammond has proved by a series of experiments that in the domestic rabbit there is no regular oestrous cycle, the animals generally continuing in a state of oestrus for prolonged periods, during which copulation can occur, succeeded by ovulation and pregnancy. It is supposed that owing to there being no corpus luteum to regulate the time when the follicles ripen, this process can occur at any time under suitable conditions. In this respect, according to Mr. Hammond, the rabbit resembles the domestic fowl and is quite different from the great majority of mammals.

The book is illustrated with twenty plates, each containing several photographs showing the condition of different organs throughout the sexual cycle.

EXPERIMENTAL PSYCHOLOGY.

THE second part of Dr. C. S. MYERS's *Text-Book of Experimental Psychology*, describing laboratory exercises, has now reached its third edition.⁴ Many new exercises, especially in the higher mental functions, have been introduced; these have been devised by Mr. F. C. BARTLETT, who succeeded Dr. Myers as director of the Cambridge University Psychological Laboratory. Mr. Bartlett's name, therefore, appears with that of Dr. Myers on the title-page. The student of psychology is advised to concentrate his attention upon the methods which he is instructed to employ, and upon getting a clear conception of the nature

² *Public Health Law: A Manual of Law for Sanitarians*. By James A. Tobey, M.S., LL.B. Baltimore: The Williams and Wilkins Company; London: Baillière, Tindall and Cox. 1925. (Demy 8vo, pp. xviii + 304. 20s. net.)

³ *Reproduction in the Rabbit*. By John Hammond, M.A. Cantab. With a Foreword and Chapter on the Formation of the Corpus Luteum by F. H. A. Marshall, F.R.S. Biological Monographs and Manuals—No. IV. Edinburgh and London: Oliver and Boyd. 1925. (Demy 8vo, pp. xxv + 210; 20 plates. 15s. net.)

⁴ *A Text-Book of Experimental Psychology*. Part II, Laboratory Exercises. By Charles S. Myers, M.A., M.D., Sc.D., F.R.S., and F. C. Bartlett, M.A. Third edition. Cambridge: The University Press. 1925. (Demy 8vo, pp. 321; 40 figures. 7s. net.)

and range of experiment in psychology. He must not be depressed by the fact that the ideal experiment, in which all the conditions are thoroughly under control, cannot be performed. "The experimentalist in psychology," says Dr. Myers, "must be a psychologist"—a statement worthy of remembrance by the lay amateur psychologists who now abound. The experiments described are divided into four sections. The first series gives a training in the technique of psychological experiment, both qualitative and quantitative. The exercises in the second section are directed to a study of the special senses. The third section contains a number of typical exercises on perception and the higher mental processes. Section IV describes additional experiments in the study of the senses and of mental activities, together with an exercise in statistical methods. The whole course of study is very clearly and completely set forth.

ESSENTIALS OF PHYSIOLOGY.

For the physiologist there can be few tasks more difficult than to decide what are and what are not the essentials of that science. The late Professors BAINBRIDGE and MENZIES carried out this selection with such discretion in their *Essentials of Physiology* that Professor LOVATT EVANS, the editor of the fifth edition,⁵ has had to reject very little that was superfluous; and he has added nothing that is non-essential.

The reader must bear in mind that this condensed work is not an introduction to elementary physiology, but a presentation of all such subjects as an examiner is likely to ask about. It is a handbook for students who want to revise their work, not an exhaustive treatise for experts. Furthermore, the student is supposed to have some acquaintance with both histology and biochemistry, for there is very little of the former, and the latter is dealt with quite early in the book. If the chemistry is to be studied thus early, then food and diet might well have followed immediately. It does not seem well to postpone until so late as is done here the chemistry of diet, digestion, and absorption. The student is not given early enough an adequate conception of metabolism. The chemistry of the blood, as is proper, is described early. Some topics are excellently done, such as the vascular mechanism and the account of diabetes and insulin; both of these are absolutely up to date. The subject of tissue respiration is another the treatment of which is as thorough as the small space allotted to it will allow. The reference on page 2 to what "are called vitalistic interpretations of physiological phenomena" is, however, too short to be other than imperfect if not obscure. The exceedingly important topic of the relations between the members of the biologic trinity—affectability, stimulus, and response—might with advantage have been more fully discussed. It is owing to hazy conceptions of their relations that we find sometimes in the writings of medical men, even of great clinical experience, a good deal of confusion as regards the exact meaning of stimulus, vital property, and response.

Considering its great practical and theoretical importance, the existence of the problem of the reality of nerve energy, a term used by physiologists and by clinicians alike, might have been recognized. No mention is made of the tracing of a muscle in a state of voluntary contraction which displays events of the order of ten to twelve a second and not any so rapid as fifty. This latter figure is obtained by the delicate galvanometric method; and some attempt might have been made to correlate this "fifty a second" with the earlier observations by the coarser method. In view of the great significance in clinical work of the understanding of "referred" sensations and pain, the treatment of this subject might have been fuller, and would have been the better for a diagram. We are glad to see the practically important subject of sleep discussed; but we can hardly agree with the rather too agnostic conclusion as to its causation. Many of the diagrams, being bold and distinct, are very helpful; those

on colour vision are especially good. We are glad to notice the frank recognition of the influence of the psychic and emotional factors on the flow of gastric juice.

This excellent presentation of the facts of physiology is what it purports to be, and may be recommended to the student with the utmost confidence.

THE HOUSE-FLY.

A SMALL manual by Major AUSTEN of the British Museum (Natural History) on *The House-Fly*⁶ and its dangers, together with a description of the means of combating them, is a veritable *multum in parvo*, meriting the highest praise. Many a medical man will find in it things which it is not only advisable but necessary for him to know, and he will do well to make a note of them to recommend to the educated among his patients at the present time when measures can most effectually be taken to prevent the usual summer invasion of these pests. The majority of persons regard the house-fly as a nuisance, but few among the laity are aware of the real dangers which may result from neglect of efforts to prevent them. The book opens with an interesting account of the life-history of the house-fly and of the differences which exist between it and others bearing a more or less close resemblance to it. The author then proceeds to enumerate some of the most important of the diseases which may be transmitted by the agency of this insect, basing his remarks on his wide general knowledge, supported by his experiences in the great war. A brief but interesting section speaks of the natural enemies of the house-fly—the ant, *Pheidole megacephala*, which destroys many eggs, larvae, pupae, and newly emerged adults; the larva of the muscoid fly, *Hydrotoea dentipes*, which feeds on the larvae of the house-fly, but which, in addition to being easily reared in captivity, is not troublesome to man and does not visit human dwellings; wasps, which attack adult flies; and the fungus, *Empusa muscae*, which also destroys many adults.

The causes of a "plague of flies" in a locality are next stated and used as the basis for formulating rational means of prevention and extermination. The last twenty-three pages, comprising one-third of the book, is devoted to detailing measures of control directed against the fly in its various transmigrations from the egg to the adult; on the ways of preventing breeding, or, in the later stages, hatching; and a final note on general precautions for preventing the entrance of flies into houses, or their access to food, and for obviating the conveyance of infection from the sick to the healthy. In a sentence, the book is one which cannot be too widely read by the educated public, and its low price brings it within the reach of all.

NOTES ON BOOKS.

DR. ALBERT WILSON has written a book, *Rambles in North Africa*,⁷ which it is rather difficult to classify. It can hardly be called a book of travel, it is not wholly a diary, and not exactly a guide-book, although to read it would be a useful preparation for visits to Algiers and Tunis. It appears to be the fruit of several trips the author made with his two daughters. He prepared himself by reading up the history, ethnology, and geology of these countries; and so presents his readers with a good deal of information a less methodical holiday-maker might neglect to acquire. The volume is well illustrated by forty-eight photographs, which are excellently reproduced.

The fourth volume of *Allen's Commercial Organic Analysis*⁸ deals with resins, rubber, and essential oils. The subject of essential oils is split up. An article by Nelson and Russell is entitled "Special characters of essential oils"; another by E. J. Parry bears a title referring to their general characters and the methods of analysing them; and under still another heading the same authority discusses them with reference to

⁶ *The House-Fly: Its Life-History, Importance as a Disease Carrier, and Practical Measures for its Suppression.* By Major E. E. Austen, D.S.O. Second edition. London: British Museum (Natural History), 1925. (5½ x 8½, pp. 68; 12 figures. 1s.)

⁷ *Rambles in North Africa.* By Albert Wilson, M.D. Edin. London: Jonathan Cape, Ltd., 1925. (Med. 8vo, pp. 296; 43 plates. 12s. 6d. net.)

⁸ *Allen's Commercial Organic Analysis.* Vol. IV. Edited by Samuel S. Sadtler, S.B., Elbert C. Lathrop, A.B., Ph.D., C. Ainsworth Mitchell, M.A., F.I.C. Fifth edition, entirely rewritten. London: J. and A. Churchill, 1925. (Roy. 8vo, pp. x + 648; 9 figures. 30s. net.)

⁵ *Bainbridge and Menzies' Essentials of Physiology.* Fifth edition. Edited and revised by C. Lovatt Evans, D.Sc. Lond., F.R.S., M.R.C.S., L.R.C.P. London: Longmans, Green and Co. 1925. (Demy 8vo, pp. viii + 536; 197 figures. 14s. net.)

their constituents. This strange division of the subject may have been occasioned by the fact that the contributors live on opposite sides of the Atlantic, but this seems an insufficient reason for placing the articles in different parts of the book, separated by others on resins and on india-rubber and kindred substances. This drawback is perhaps not very serious, for the several articles have somewhat different aims, and it is easy to find any required items of related information in the different parts. There is a useful table, arranged in alphabetical order, summarizing the important characters and constituents of all essential oils. The chief purpose of the work, which is to characterize materials in order to enable authentic specimens to be distinguished from spurious, has been consistently followed, and has been fulfilled in high degree. Descriptions of the nature of the source, of the methods of production, and of the qualities that render the materials adapted to their special uses, add to the value of the articles. The adulterations which experience shows may be encountered are cited, and the analytical methods by which sophistication can be detected are described. The volume is a fitting member of the series of which it is a part.

PREPARATIONS AND APPLIANCES.

Combined Bone and Plate Holding Forceps.

MR. K. F. D. WATERS, M.B., Ch.B. Oxon. (St. Stephen's Hospital, Fulham Road, S.W.), writes: I have had in use for nearly two years a combined bone and plate holding forceps, which has given every satisfaction.

The forceps consists of two blades made on the principle of the well known Peters forceps for large or small bones. The blades are adjustable and held where desired by a spring rack at the end of the handle. The advantages are that as soon as the fragments have been manipulated into position the clamp can be locked instantly and maintain the correct alignment while the bone is secured with the plate, which is slipped under the groove in the upper blade without disturbing the position of the fragments. The operation thus becomes much easier and shorter and no assistance is required, except to help in bringing the fragments into apposition. This forceps was made for me by J. H. Montague, 69, New Bond Street, W.1.

THE DEFINITION OF BLINDNESS.

BY

N. BISHOP HARMAN, M.A., M.B. CANTAB.,
F.R.C.S. ENG.,

SENIOR OPHTHALMIC SURGEON, WEST LONDON HOSPITAL.

THE Ministry of Health has recently issued a circular on the definition of blindness in relation to the training and employment of the blind¹ which is of much importance to ophthalmic surgeons and to those who have to do with the administration of the Education Acts and the Blind Persons Act. The chief part of the circular is the promulgation of a precise numerical definition of blindness. The definition is said to be that contained in the report of the Ophthalmological Section of the Royal Society of Medicine of 1915.² A part of that report is quoted in the circular and sandwiched between a prefix, which reads: "The report states that precise numerical formulæ of visual acuity are useful as guides," and an affix: "It is accordingly the practice of the Minister to regard persons whose visual acuity, after correction of refractive errors, is greater than 6/60ths (Snellen), as not being blind, unless the defect of eyesight includes such special conditions as a great contraction of the field of vision." The report of the Royal Society of Medicine, as arranged in this circular, appears to furnish a sure foundation for this decree of the Ministry. When the terms of the report are verified it is found that the Ministry has made a somewhat disingenuous use of that document. In fact, it has used it in just the opposite fashion to that those who drafted it intended. The whole relevant portion of the report reads thus:

"... Let the definition read 'too blind to perform work for which eyesight is essential,' and his case is covered.

"The Committee has carefully considered the advisability of supplementing the foregoing definition by numerical standards expressing degrees of blindness. Experience shows that persons whose acuity of vision (refractive error being corrected) is below one-twentieth of the normal (3/60 Snellen) are usually unable to perform work requiring eyesight, while persons with

vision better than one-tenth (6/60 Snellen) are usually able to perform some such work. Persons with intermediate degrees may or may not be able; much depends on intelligence and bodily strength, and much on the nature of the blindness. A person whose so-called blindness depends on defects in the centre of the visual field may fail to reach a given standard and yet be able to perform some kinds of work requiring eyesight, while another person suffering from great contraction of the field of vision may surpass the same standard and yet be unable to walk alone or to do any kind of work requiring eyesight."

"The Committee is of opinion that the numerical limitations mentioned above are likely to be useful as preliminary guides, but that until experience has been gained through the working of the Act they should be regarded as purely tentative. The certifying authority should not be bound by any precise numerical standard."

The part of these paragraphs quoted by the Ministry in its circular are those between the heavy black lines¹¹ interposed in the extract. The opening part of the second paragraph is omitted; that is immaterial. But what does matter is the complete suppression of what is really the essential part of the report shown in the third paragraph, which concludes: "The certifying authority should not be bound by any precise numerical standard." (Italics mine.)

Such a use of the report of the Royal Society of Medicine by a Government department of such high standing as the Ministry of Health is little short of amazing. The report does suggest that there may possibly come a time when some revision of the definition of blindness may be desirable in the light of experience. The Ministry must be in possession of a large volume of records. It would have been reasonable for the Ministry to have referred this collected material to the same body as drafted the report; and to ask for suggestions in the light of that material. Or, alternatively, the Ministry might have stated that in view of its own accumulated experience it considered that the definition should now carry a hard and fast numerical formula; that would have been a strong position to assume. Its action, as shown in this circular, is indefensible, since it is based upon an alleged opinion which was not only not formulated, but explicitly denied.

Blindness is relative. Strictly speaking, a man is blind if he has no perception of light. Ability to distinguish light in any degree removes him from the group of the totally blind. Such a definition is useless in a civilized community. Economic blindness may, and does, allow of considerable degrees of sight—sight that will not only be a comfort to its possessor, but also of utility. Possession of perception of light is an incalculable comfort; ability to judge the position of a light is greater; power to count fingers greater still; and each advance brings not only more comfort but some additional freedom of action. Yet none of those valuable degrees of sight renders its possessor economically sighted—that is, his sight does not bring him within the ranks of those who live by sight. He is for all purposes of his daily work blind. With advancing degrees of sight—for example, the ability to define the shape of objects—approach is made to economic sight. The point at which this sight becomes sufficient to enable work to be done by sight is the limit of economic blindness. That point is not and cannot be a numerical standard of vision which is an unrelated formula. It can only be related to work, which is variable both in time and place.

The relativity of visual standards is well known when these are applied to sighted persons. There is no fixed standard for all. In naval affairs perfection is the standard, yet even here allowance is made for the clerical staffs. The standard for the soldier is lower, and it is lower in times of war than in peace. The standards for children vary with age. The standards for vehicle drivers vary with the railroad and the road car. In setting these standards the prime reference is not to some hard and fast formula but to work, or the nature of the work to be done.

Since experience has shown that this must be so among the sighted, there can be no grounds for ignoring a like necessity in dealing with those at the other end of the scale who are alleged to be economically blind. A fixed standard, such as is promulgated in the circular of the Ministry, does this very thing. It assumes that a visual acuity of 6/60 is the dividing line between economic blindness and sight—for the whole country; for those born blind;

¹ *Welfare of the Blind: Training and Employment of the Blind: Definition of Blindness.* Ministry of Health. Circular 681. London: His Majesty's Stationery Office, 1926. Price 2d. net.

² *Proceedings of the Royal Society of Medicine, Section of Ophthalmology, Report on the Definition of Blindness.* July 21st, 1915.

for those blinded in later years; and for all causes of blindness (with the exception of limitation of field of vision). That assumption is the antithesis of our manner of dealing with the sighted.

The change inaugurated by the Ministry from the original agreed definition, "Too blind to perform work for which eyesight is essential," to the rule of thumb of 6/60, will be viewed both with relief and disgust. Measuring human capabilities is confessedly one of the most difficult forms of judgement. That judgement can only be gained by progressive, strenuous, and continued mental exercise and comparative examination. To require an ophthalmic surgeon to judge whether an alleged blind person is economically blind on the original definition is to require him to exercise all his trained faculties of judgement. To tell him to find out whether or no the same person sees 6/60 is to set him a technical task and no more; he may even do this without any consideration of the purpose of the test, for it calls for no examination of the facts of life outside his consulting room. However many such cases he may examine his judgement of economic blindness is not advanced. The good observer is likely to suffer a dejection in judgement; the mere technician will remain as he is. I heard someone say: "The 6/60 definition helps the fool," and I would add—it leaves him a fool. The 6/60 definition may be held to be an administrative convenience; it favours comfortable docketing. That is true. But it is a poor reason for supporting it. It is on a par with the yearning of some minds for a tabular list of diseases with a parallel list of cures. A simple plan for the simple-minded. Administrative convenience is not to be ignored.

But is this 6/60 definition really an administrative convenience? I do not think it is. It is likely to lead to more difficulties and more hard cases than the fluid original definition of the Royal Society of Medicine, and with each hard case there will be an outcry against the administration. Under the Royal Society of Medicine's definition the administration takes the opinion or opinions of qualified doctors and acts thereon; under the 6/60 definition the administration assumes the responsibility, for it has set the standard.

Hard cases are most likely to occur in industrial centres where a high organization of work makes disabilities most serious; and also because in these centres complaints are more easily advertised. A man in the country with 6/60 vision can do work for which sight is essential; the Ministry's definition will accept him as blind. A man in a great city with a little more sight than 6/60 in one eye, the other as likely as not exsiccated, cannot get work for which sight is essential; no one will employ him when there is a good-sighted competitor at hand; yet the Ministry's definition counts him as sighted and employable as a sighted man. A man who never had more than 6/60 vision all his life is in an incomparably better position by use and custom than the bewildered adult who has just suffered a grave reduction of previously good sight through disease or accident. Yet the Ministry's definition lumps both together. It would be easy to add to this demonstration of the inequalities of the 6/60 definition of blindness, and of the likelihood of increasing administrative difficulties that will arise therefrom.

It is to be hoped that further experience may lead the Ministry to modify its circular, and possibly substitute for the somewhat mutilated extract of the report of the Royal Society of Medicine an extract which will show the finding of that report in its true relations. The repeated publication of this finding (as quoted earlier in this paper) would be of service.

Further, it would be of service to ophthalmic surgeons if the Ministry would publish a series of cases passed as blind, with the clinical findings upon which the decision was based. The advantage would be still greater if the Ministry of Health would do this conjointly with the Board of Education, the latter department citing cases certified for "blind training." The publication of a short and representative series of cases would do more to help isolated workers than any rule of thumb formula, just as in another sphere "case law" is the inevitable exposition of the wisdom of the Legislature. Such a joint publica-

tion is the more necessary seeing that the circular shows that the Board of Education has agreed that—

"No student should be admitted to a course of training designed for persons who are too blind to perform work for which eyesight is essential in accordance with the interpretation of that definition indicated above, unless in the opinion (based on competent medical advice) of the managers of the institution and of the local education authority or other contributing body, he either is, or there is a reasonable prospect that by the time his training is ended he will be, blind within the meaning of the definition."

This paragraph of the circular concludes with a most weighty recommendation:

"It is of great importance that local education authorities and managers of special schools for the blind should arrange for the case of every child to be brought under review during the last year of his school life from this point of view, in order to ensure that the provision made for his training or other form of after-care shall be appropriate to his needs."

Some workers for the blind are inclined to think—once blind always blind. This is not true. Diagnosis must be subject to revision, for conditions may change. A child blind from interstitial keratitis may in later years attain serviceable sight. A child with congenital eye defect may be seen at such an age that vision cannot be satisfactorily determined. It may properly be certified as blind for educational purposes at the time, but the decision must be revised repeatedly. I remember the case of a boy with dislocated lenses who was in a provincial school for the blind until the age of 16 years, then he was seen in London, and excellent vision was obtained by the supply of cataract glasses. I hasten to add that the case occurred twenty years ago, and at the time there was no ophthalmic surgeon attached to the school; and that I have seen no similar case since. The requirement that there should be an examination of children in schools for the blind in the last year is the minimum; it would be better if the revision were annual. When education authorities have no choice between a school for the blind and an elementary school difficulties will arise, but where they have established "myope classes" there is no difficulty in securing suitable transfers and making trial of different educational methods. The formation of myope classes becomes an urgent necessity under the new conditions.

Another point of importance is referred to in the circular. The Minister "regards it as essential also that only visual factors should be taken into account, and that other bodily or mental infirmities predisposing to incapacity should be disregarded." A cripple may be unemployable, but that is no reason for certifying him as blind. One such improperly certified may possibly exclude a really blind person from opportunities of training of which he is in urgent need, and of which he may be able to take full advantage.

Irrespective of the criticism I have ventured to make of the action of the Ministry regarding the definition of blindness, there can be no doubt that the circular is one which demands the study of all ophthalmic surgeons.

ROYAL MEDICAL BENEVOLENT FUND.

At the last meeting of the Committee thirty cases were considered and £488 voted to twenty-eight applicants.

Daughter, aged 49, of M.D. Edin. who died in 1919. She has tried to maintain herself, but owing to ill health and bad eyesight has had to give up work, and is now living on her capital, which only brings in £17 per annum at the present time. Friends gave £12, and she received £2 10s. as a lady help for two months. Voted £20 in four instalments.

Daughter, aged 70, of M.R.C.S. who died in 1868. Applicant worked as a children's nurse for twenty-four years, and as a housekeeper until a recent illness; she is now unable to do anything. Is applying for the old age pension, but her only income is £2 17s. 6d. a year; she lives with a friend who is unable to keep her. Voted £25 in twelve instalments.

Daughter, aged 62, of L.S.A. who died in 1914. She has a small nursing home, but only received from patients £103. She has borrowed money to meet rent, which is £56, with rates £20. Voted £10.

Widow, aged 55, of L.S.A. who died in March over 80 years of age and needed constant attention. The Fund granted her £15 to meet out-standing rent and to carry her on whilst seeking work.

Widow, aged 40, of M.B. Glas. who died in 1924. Her son, aged 15, is now apprenticed to a firm of engineers. He is in charge of a guardian as the applicant is lying seriously ill in an infirmary. The guardian was voted £25 in twelve instalments towards maintenance of the boy.

Daughter, aged 44, of M.R.C.S. who died in 1906. She has been an invalid since his death and is looked after by a nurse, who receives 15s. a week for her maintenance. £175 has been granted since 1919, and the annual grant of £25 in twelve instalments was renewed.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters Symonds, at 11, Chandos Street, Cavendish Square, W.1.

British Medical Journal.

SATURDAY, MAY 29TH, 1926.

THE WHITE MAN IN THE TROPICS.

THE question of the ability of white people to colonize a tropical country and make it a place of permanent residence has been much debated for many years. The general verdict has usually been adverse, given by those who have held positions of responsibility for considerable periods in the districts of which they speak and write, either in Government service or in the employment of commercial firms, and their opinion has sometimes been supported by scientific men who have carried out physiological and biochemical investigations regarding the effects of climate on the constitution of the European. On the other hand, we have some important practical examples to the contrary effect, among them a large unpremeditated experiment in acclimatization in Queensland, where a large resident pure-blooded white population has been bred up during the last seventy years. On the eastern coast alone there are more than 100,000 such.

In most tropical countries the white man is an official of one sort or another, an overseer of labour, a temporary sojourner and not a lifelong resident, content to pass the time and put up with discomforts and the use of makeshift dwellings and appliances, and carry out his duties with the ever-present vista before him of a comfortable retirement to a temperate climate when the time of his service expires. Such men are no true criterion of the adaptability of the white man to the tropics, for there is amongst them no true community of interest, no true civic pride, while the lack of home comforts is a constant source of complaint, and the collar-work in surroundings perhaps not too congenial produces unwittingly a psychological impression of the country which is biased and unjust.

If the lot of the exiled man is hard, that of the white woman is even harder in its mental and psychic stress. Woman's main interests all the world over are vested in her children, her home, her friends, and outside pursuits. Many white women in the tropics are averse to having, or even refuse to have, children because they have been told that pregnancy, and especially parturition, is fraught with more risks and disastrous consequences than at home. The majority of those who do have children do not suckle them, but leave them largely to the care of native nurses, and send them home when they arrive at the most engaging age for fear of the climate or the moral influence, and there is for months prior to this separation the strain of deciding whether her duty is to leave her husband and watch the growing child, or risk sacrificing the affection of her child in order to carry out her duties to her husband. The second interest, her home, is in ninety-nine cases out of a hundred left almost entirely to be run by native house-boys, whose language she rarely troubles to learn, who, she knows, are probably cheating her and wasting an already too slender income—an ever-present anxiety and source of worry. Thirdly, her outdoor interests are few; many of them are trivial duties which she feels must be performed; she suffers, in fact, from the effects of lack of physical exercise, worry, and ennui.

In the face of this we have the striking contrast

presented by the inhabitants of white Australia, the incontrovertible fact of a white people thriving and successful to the third generation. How are we to account for the difference? The essentials may be summed up almost in a sentence. The European here is not a mere sojourner looking forward to the time when he can retire to Britain for a well earned rest; there is no subordinate native race to supervise as his chief or sole occupation in life; the residents are working men and women carrying out, unaided, every task that life thrusts upon them, from the most laborious household duties to the higher grades of mental effort.

Twenty years ago, when Kanaka labour was forbidden in the cane-fields, the knell of the sugar industry in Queensland was thought to have been sounded. The yield in that year (1905-06) was 152,259 tons. Since that date there has been none but white labour, yet in 1922 the yield was 288,000 tons, an increase of more than 80 per cent., and white Queenslanders to the third generation are carrying on their work as in temperate climates, but show no indications of any detrimental effects. Dr. Cilento states¹ in a recent report that in Townsville there are "no labour-saving devices, no special laundry facilities, and the housewife has to go out and purchase her meat and groceries and carry them home, chop wood for fires, milk several goats, get ready the meals, dress and send the children off to school, and then set about sweeping and house-cleaning," and yet she keeps perfectly fit. In fact, Queensland has a lower death rate than the Commonwealth as a whole, and the infantile mortality is lower. In 1913 the death rate in Queensland was 10.4 and the infantile mortality 63, as compared with 13.8 and 108 respectively in Great Britain. A long discussion took place at the Australasian Medical Congress in 1920, and the conclusion reached was that no inherent or insuperable obstacle could be found in the way of permanent occupation of tropical Australia by a healthy indigenous white race. The whole question is fundamentally one of applied public health, the two essentials being physical exercise and work, and preventive medicine. Apart from heat exhaustion, heat-stroke, sun-stroke, and ocular conditions such as glare-asthenopia, the pathological effects of climate *per se* are few. Confirmation of the Australian findings is seen in the records of the long history of white families resident in Kisar in the East Indies, in Caba in the West, in Espiritu Santo, and Santa Katharina. Also, by far the greater part of the morbidity and mortality amongst the Americans in the Philippines is ascribed to nostalgia, isolation, tedium, excesses, and parasitic infections. Gorgas in Panama bore similar testimony.

It is largely the persistence in habits unsuited to the climate that is the cause of the discomforts and dangers of tropical residence; much of the morbidity attributed to climate is in truth the result of faulty habits. Among such habits may be mentioned wrong methods of clothing, producing discomfort and heat exhaustion; the stimulant effect of new scenery and food, causing increased appetite and leading to over-eating; while the heat and excessive perspiration make the acquirement of the drink habit easy, and foster a tendency to laziness. Diminished lung metabolism throws more work on the liver, and physiological hyperaemia passes into pathological congestion and

¹ *The White Man in the Tropics*. By R. W. Cilento, M.D., B.S., D.T.M., and H. Dir. of Tropical Medicine, Commonwealth, 1925. Service Publication (Tropical I). H. J. Green, 1926. (Roy. 8vo, pp. 168; 22 figures.)

upset of function, with its resultant symptoms. The alkalotic blood state produces a sense of fatigue and depression, which should be neutralized by muscular effort. The irritability and neurasthenia ascribed to climate are not confined to the tropics, but will occur in all places where overfeeding, lack of exercise, excesses, monotony, and absence of creative interest are rife. In the tropics, with more leisure, the patient realizes his "state of drift," tries to adjust matters, feels jaded and loses his self-confidence, and the syndrome is aggravated. The climate is only a contributory factor; the cause of the "camelious hump" is not having enough to do, at any rate physically; the remedy is obvious, and its efficacy has been proved in Queensland and elsewhere. This seems to be the general outcome of the very interesting correspondence in our columns aroused by a letter from the Bishop of Singapore on mental irritability and breakdown in the tropics, published last March (p. 503). The similarity of the opinions expressed is on the whole remarkable, for the letters have been founded on experience gained during medical practice in many parts of the tropics. The question is really one for clinical decision, for it must be remembered that the climatic conditions vary greatly in the tropics, and consequently the specialized observations, physiological and biochemical, recorded by laboratory workers are not applicable generally.

There is a widespread belief that tropical climate is responsible for a definite anaemia, and that the pallor is a sign of ill health; this has no true foundation. The pallor of the tropical resident is due to ischaemia, from heaping up of the surface epithelium—significant only of an adaptive protection. On the contrary, it is more correct to say that a ruddy complexion in white residents in the tropics is a probable sign of ill health or alcoholic excess.

Shibboleths die hard, and the old saying that the white man in the tropics loses 25 per cent. of his energy yearly, and is, therefore, good for nothing at the end of four years, is often quoted. If he tries to keep up European habits and customs as regards clothes, meals, hours of work, and omits all common-sense precautions, this is probably true; but if he is properly housed, properly clothed, and takes reasonable care in the way of personal prophylaxis, works hard, and has a hobby which entails exercise, and if public health measures regarding water supply, drainage, and refuse disposal are attended to by a conscientious health officer, it has yet to be proved that the white race cannot live and thrive as well in the tropics as in a temperate climate.

COLOUR-BLINDNESS.

THE name of Edward Nettleship is among the great ones of ophthalmology. He was in the succession of Bowman, von Graefe, and Donders, but his mind was of a philosophical cast, and he was particularly interested in hereditary defects, and comparatively early in life he retired from practice in order to devote himself entirely to the study of this subject. His pupils founded a medal in his honour, which, at his request, is awarded for the encouragement of scientific and ophthalmic work. His best memorial, however, has been erected by Professor Karl Pearson, who has devoted one of the fine volumes of *The Treasury of Human Inheritance*¹ to the subject of hereditary

diseases and anomalies of the eye, to stand as a Nettleship Memorial Volume and record of Nettleship's own work and that of his immediate students and friends. Part I, which was published in 1922, and was reviewed by us in the issue of March 17th, 1923 (p. 472), contained an account of the life of Nettleship and dealt with the subjects of retinitis pigmentosa and allied conditions, congenital stationary night-blindness, and glioma retinae.

Part II, which is now published, is devoted to colour-blindness, and under the capable authorship of Dr. Julia Bell exhibits to the full the high standard of workmanship that we are accustomed to expect from the Cambridge University Press. The volume, indeed, may be considered as an *édition de luxe*, which will give equal satisfaction to the bibliophile and man of science. An excellent reproduction of C. Turner's engraving of the portrait of John Dalton by Lonsdale forms an appropriate frontispiece, since Dalton was the first to give a scientific description of colour-blindness. Dalton, however, was not the first to recognize the affection; the credit of the earliest observation appears to belong to Dr. Turberville of Salisbury, who, writing in 1684, states that "a maid two or three and twenty years old came to me from Banbury, who could see very well, but no colour beside Black and White." A few more cases were recorded in the course of the next hundred years without attracting notice, and it was not until 1794 that Dalton observed the anomaly in his own vision and made a scientific study of the subject, thus inaugurating an epoch of research, not only into colour-blindness, but into colour-vision itself. He tells us how his attention was drawn to the subject: "I was always of opinion that several colours were injudiciously named. The term pink in reference to the flower of that name seemed proper enough; but when the term red was substituted for pink, I thought it highly improper; it should have been blue, in my apprehension." An interesting account is given of Dalton's observations, and one of the most attractive features of the whole volume is a letter to him on the subject from Sir John Herschel. This letter, which is in the possession of Professor Pearson, and is now published in its complete form for the first time, affords a notable insight into the fine nature of the writer. Numerous references to the views of thinkers of ancient and modern times, from Plato downwards, add interest to the volume, and particularly noteworthy is the discreet manner in which Galea deals with the difficult subject of colour-vision; "I would explain to thee in few words," he says, "O thou hideous blasphemer of Nature, if I did not well know that thou would'st contradict when I came to explain the act of vision." With many interesting details of this kind the authoress introduces the subject in a brief historical sketch, and then proceeds to a discussion of the main subject under the headings of normal colour-vision, congenital total colour-blindness or achromatism, and congenital colour-blindness or dichromatic vision.

The characteristic feature of total congenital colour-blindness is held to be an inability to recognize any tints but black, white, and grey; and although such cases are rare, and there is considerable difficulty in demonstrating a total inability to recognize colours, there are a few instances on record which appear to prove that the condition does exist. The problems connected with this form of colour-blindness have reference to the relation it bears to certain symptoms that usually accompany it, more especially amblyopia, photophobia, and alterations in the visible spectrum; to the probable nature and seat of the anomaly; and

¹ *The Treasury of Human Inheritance*. Edited by Karl Pearson, F.R.S. Eugenics Laboratory Memoirs, XXIII. Francis Galton Laboratory for National Eugenics, London. Volume II: *Anomalies and Diseases of the Eye* (Nettleship Memorial Volume). Part II: *Colour-Blindness*. By Julia Bell, M.A., M.R.C.S., L.R.C.P. Cambridge: The University Press; London: H. K. Lewis and Co. Ltd., and Wheldon and Wesley, Ltd. 1926. (Roy. 8vo, pp. 125-267, 4 plates, 1 portrait. 45s. net.)

to the anatomical changes that accompany it. With regard to the first point, five cases are cited in which there is definite evidence that total colour-blindness may be associated with perfectly good vision, although it is exceptional for the visual acuity to be higher than one-third of the normal. In this connexion a comparison with the changes met with in albinism are instructive. Albinism exhibits a syndrome closely resembling that of total colour-blindness, except that colour-vision itself is retained. In this condition the fovea is absent or imperfectly developed, and Dr. Julia Bell suggests that if the amblyopia and other symptoms common to the two diseases are due to this defect, we must look for some further defect in achromatism to account for the absence of colour-vision; and that possibly the presence of central scotomata and the alterations in the visible spectrum observed in achromatism have a bearing on this point. There seems to be no doubt that the spectrum seen by the totally colour-blind is identical with that seen by the normal eye under the condition of dark adaptation—that is to say, the red end of the spectrum is shortened, the brightest region is displaced from the yellow towards the green, and the stimulative action of the short-waved rays is much increased. It would appear that in this condition the macular region is not functioning, and that vision is carried on in the peripheral areas; such would seem to be the case, for instance, in retinitis pigmentosa. The eye is in an irritable state, the pigment is withdrawn from the percipient elements, and the retina is sensitive to slight stimulation. It is possible, therefore, that total colour-blindness is due to the fact that stimuli from any wave-length produce vibrations affecting too wide an area, and thus tend to bring about a sensation of all colours, and so of white and grey.

With regard to the anatomical changes associated with total colour-blindness, the observations are meagre. Two cases only are on record in which a microscopical examination was carried out; in one the eye and optic nerve were normal, and the colour-blindness was attributed to some central lesion; in the other the cones of the foveal region were found to be imperfectly developed. Hereditary influences play a very limited part in the causation of congenital total colour-blindness, for about 20 per cent. of all recorded cases appear to have no similarly affected relatives and show no other hereditary defects. On the other hand, a very high proportion of cases are the offspring of consanguineous parents, and this factor is almost certainly of great significance.

The more common form of colour-blindness—dichromatism or congenital colour-blindness—contrasts sharply with the total form, in that it is strongly inherited, belonging to that group of inheritable diseases which is mainly manifested in males and transmitted by their unaffected daughters, but not by themselves directly to their sons. Dichromic vision is usually considered to be characterized by a defect in the recognition of both red and green, the defect being more marked sometimes as regards the red, sometimes as regards the green, and in either case with varying intensity. Much controversy has centred round the question whether the mental picture normally stimulated by yellow and blue does in fact correspond to the two colours seen by dichromates. According to the theory elaborated by Edridge-Green it does not. He appears to consider that in the evolution of colour-vision the first two wave-lengths to be differentiated as colours are those at the extreme ends of the spectrum, and that the power to react specifically on

stimuli from these regions is what is retained by the dichromic eye. Dr. Julia Bell devotes considerable space to the discussion of the question, and finds difficulty in accepting this conclusion. Perhaps the most forcible argument against the Edridge-Green theory is afforded by cases of unilateral colour-blindness, since in them the affected eye can be tested against the normal one. Careful examination of what appear to be genuine congenital cases seems to leave little doubt that the two retained fundamental tones are yellow and blue. Other characteristics of dichromic vision are its persistence, its frequent association with perfectly normal vision for form, and an enhanced sensibility for gradations of light and shade; the colour sense also appears to be definitely changed in character under artificial light. With regard to inheritance, although rare in women, ninety-one cases of its occurrence in the female are on record. Further, it has been asserted that for colour-blindness to become manifest in women the father must be colour-blind, the mother must be a carrier, and the sons of the colour-blind woman must be colour-blind. Dr. Bell is able to deny this assertion, in so far that the record of one sibship contained three colour-blind females, whose father had normal colour-vision; and in several cases colour-blind women have been demonstrated to have sons with normal colour-vision.

THE MEASUREMENT OF X-RAY DOSAGE.

THE annual Mackenzie Davidson Memorial Lecture, under the auspices of the Röntgen Society and the Section of Electro-Therapeutics of the Royal Society of Medicine, was delivered on May 20th by M. Alexandre Dauvillier, D.Sc., of Paris. The subject of the lecture was the measurement of x-ray dosage, and the lecturer described at length certain experiments of his own. An international committee on dosage was formed as the result of the Congress of Radiology held last year in London, and no doubt the committee will find much material in Dr. Dauvillier's lecture, even though the result may be to give them a keener appreciation of the extraordinary difficulties in the way of arriving at definite international units of measurement of x-ray doses. Dr. Dauvillier began by pointing out that the thermal, chemical, and biological actions of x rays are all due to the ionization produced by the fast-moving electrons which are liberated in the rays in matter, whether the matter be solid, liquid, or gaseous. From the biological point of view the simplest hypothesis, he said, was that the ionization resulted in electrical neutralization of the essential intracellular colloids. For a given absorption of energy this ionization was independent of the speed of the radio-electrons; therefore the action of x rays was not governed by their wave-length, a point which was also borne out by the critical examination of certain experimental work. The question was how the action of the rays, which was proportional to the ionization produced in the material irradiated and to the energy of the radiation, varied for each unit of volume of the irradiated area. It had been shown that in deep therapy the scattering of x rays was a much more important factor than the selective absorption. The therapeutic problem of dosage might, he thought, be stated in the following terms: given a lesion at known depths from various specified points on the surface, what should be the period of irradiation under given geometrical and electrical conditions to cause the absorption of sufficient energy to bring about the desired biological reaction? The work of Dessauer and others had shown that deep doses could not be calculated from a knowledge of the intensity of the incident radiation and the absorption

coefficient of the tissues. The rays of short wave-length necessary for deep therapy in order to get the requisite penetration were scattered far more than they were absorbed by such light substances as air, water, and the living tissue, and experiment showed that these scattered rays played a considerable part in the magnitude and distribution of what the lecturer called "isodosic surfaces." The volume effect resulting from this scattering might in certain cases treble the dose calculated from the geometrical law. Such doses could only be determined by experiment, and the lecturer proceeded to describe experiments in which a vessel of water—the "water phantom"—possessing an absorption practically the same as that of the tissues was used. In this vessel a small ionization chamber filled with air was set, and was attached to an electrometer. A number of different empirical units had been proposed for measuring the quality and quantity of α rays, but with the exception of those of Villard and Szilard, which were unfortunately impracticable for other reasons, none of them was suitable for adoption as an international standard. Such a unit should be applicable equally to radium therapy and phototherapy, and easily reducible to the centimetre-gram-second system. The ideal method would be a spectroscopic one, but this had certain practical difficulties, and in addition a spectrogram gave no clear idea of the distribution of energy according to wave-length. Nevertheless, M. Dauvillier thought that the practical problem of a spectroscopic unit might be simpler than the theoretical, for the reason that the rays used in treatment were usually filtered and so extended over only a limited range of wave-lengths. It seemed as though it would be sufficient for medical requirements if the rays were characterized by an effective wave-length determined by measuring the coefficient of transmission through a given filter. It would be easy then to characterize the quality of α rays which had passed through filters by their effective wave-lengths expressed in Angström units, or, better still, in the X units of Siegbahn, which are thousandths of an Angström. He also discussed methods of arriving at the quantitative measurement, for which it is necessary to know both the intensity or power of the rays and the energy or total dose absorbed, the biological action depending on both these factors. Here the construction of a standard ionization chamber was necessary, by comparison with which dosimeters could be graduated; but there were very stringent conditions which dosimeters must satisfy, and these he laid down. He believed that the expedients he proposed, although they were yet too novel to have received the consecration of practice, were capable of realization, and that the problem of dosage was already on the way to a precise solution.

THE COLLEGE OF NURSING.

THE letter signed by the medical members of the Council of the College of Nursing will, we feel confident, make a strong appeal to the medical profession. It is almost unnecessary to insist on the deep debt owed to nurses, and none are better able to estimate the exacting nature of their work than those engaged in the practice of medicine and surgery. They know also how true it is that the remuneration nurses receive is not comparable to that obtained in many other walks of life, and that their working life is short; there is no general pension fund for them, although they themselves have made gallant efforts to remedy this deficiency. We believe that many more members of the medical profession than have already done so will be willing to subscribe to the endowment fund now being established, for £878 has been received without any very general appeal. The amount required is £100,000, and of this £67,000 has already been raised, £35,000 by

the members of the college and their friends. The college, which has now over 25,000 nurses on its register, has forty-one branches, seven residential and other clubs, and two convalescent homes. The college awards scholarships for post-graduate work; it has a loan fund, and a scheme for insurance against sickness and accident. The object of the college, which was founded in 1916, is to provide a central organization, to raise the standard of training and examination, to promote the higher education of nurses, and to attract to the nursing profession the best type of woman. The qualification for membership is three years' training, and the council is elected by nurses on the register. Donations may be sent to Dr. Comyns Berkeley, the honorary secretary, at the College of Nursing, Henrietta Street, W.1. The appeal says "donations of any amount," but we suspect that such appeals sometimes fail to attract all the support they deserve because people are shy of sending small donations. One way of getting over this is to find somebody in each town or district who would be willing to receive small donations and send them in a lump sum. The house of the College in Henrietta Street is to be opened by the Queen on Monday next, May 31st.

THE DECLINE OF TYPHOID FEVER.

It has been maintained with some show of reason that the decline of typhoid fever in Britain is simply a result of the general improvement in the purity of drinking-water. In lands less blessed than ours with water sources the incidence of the disease continues high. In our own country the decrease of typhoid and the increase in purity of water have proceeded side by side. This, however, is not the whole truth. Typhoid fever, while greatly diminished in Britain, is by no means totally extinct, as we have had occasion to point out several times during the past year or two; when it occurs, epidemically or otherwise, it may show itself in areas whose water supply is quite above suspicion. Pure water is good for the control of typhoid, but not by its purity alone. There are other forces at work. An interesting commentary on some of the influences which affect the spread of typhoid has been published by Dr. John T. Wilson, lately medical officer of health for Lanarkshire, in his review of the prevalence of typhoid fever in the county from 1891 to 1924. Various outbreaks which took place in Lanarkshire during these thirty-four years are set forth in order. A few of them only, dated before the water resources of the area had been developed, are traced to drinking-water. For the recurrent prevalences of the earlier years of the period and incidental outbreaks later, the main cause ascribed is personal contact in the presence of low standards of living, associated with the employment of the conservancy method for the disposal of excreta. Milk infection also played its part on a number of occasions. During the seven quinquennia beginning in 1891 and ending in 1924 the annual average numbers of cases of typhoid fever in Lanarkshire, on a population at the census of 1911 of 302,615, were 560, 422, 357, 258, 130, 93, and 65 respectively. This progressive decline reflects the sanitary progress of the county over the period, including especially the general provision of public water supplies. Collected on high hill gathering grounds and piped to the houses of the people, these supplies are pure, abundant, and accessible. Their purity is indicated by the fact that water-borne infection practically ceased on their introduction. Their abundance and accessibility are among the other forces to which reference is made above. A copious and convenient provision of water disposes to personal and household cleanliness, and enables the degrading and dangerous conservancy methods of disposal to be superseded by the water-carriage system. Standards of living almost inevitably rise, and amenity

replaces squalor. The purest water, if limited in amount, could never produce these results. If plenty, however, be combined with purity the whole area of supply becomes an unfavourable field for the propagation of typhoid by contact. Among cleanly people, with cleanly ways and living in cleanly quarters, the risk of infection by carriers or missed cases or cases nursed at home—the last exceptional in well organized districts—is very greatly reduced. Some populations on whom the benefit of water, pure and plentiful, has been bestowed may be slow to rise to their opportunities; but once a satisfactory standard of living has become general the elimination of typhoid fever from this or any other country, even apart from the aid received from specific methods of control, will be notably accelerated.

THE HEALTH OF NEW DELHI.

IN a discussion at the Royal Society of Arts on May 7th, with Lord Hardinge of Penshurst in the chair, Sir Hugh T. Keeling, a member of the Delhi Imperial Committee, who has been chief engineer in the construction of the new Delhi, gave some account of the health conditions of the future capital of India. He said that one of the reasons governing the choice of the site, south of the old city, capital of the Mogul Empire, in preference to the other suggested site to the north, was the greater healthiness of the southern position. In deciding on the site the committee, of which the late Sir C. P. Lucas was chairman, had before it a malarial survey made by Captain (now Lieut.-Colonel) S. R. Christophers, I.M.S. (*Malaria in the Punjab. Scientific Memoirs . . . of the Government of India, 1911*), which showed a spleen rate for the northern site of 90 per cent., and for the southern of 26 per cent., so that from this point of view the northern site was out of the question, and a further consideration was that the northern site was subject to floodings from the Jumna. From the commencement of the work on the new Delhi a health officer was attached to the staff in order to look after the health of the people employed, and especially to prevent the breeding of the anopheles mosquito, with the result that the spleen rate, which in 1911 was 26 per cent., was now considerably under 15. Sir Hugh Keeling also stated that the labour force employed on the works numbered at the outset 29,000, and after the war, by which time the preparation of the site had been almost finished, the labour force on the site itself and at the quarries, which were rather more than a hundred miles away, was from 15,000 to 20,000. The health administration had succeeded so well in keeping this army of labourers free from epidemics of cholera and plague that from the commencement of the work until the speaker left it last year the only epidemic experienced on the site was the Spanish influenza of 1918. Cholera and plague had visited the surrounding regions, but neither had been experienced in an epidemic form within the area of the building operations of the new city or at the quarries. He put this down to the watchfulness of the health staff and to the fact that from the first a filtered water supply had been installed. Moreover, since "Baby Week" was established in India the infant population of the area involved in the building of the new Delhi had carried off the best prizes and the majority of the prizes, and had completely "knocked out" the infants of the old city adjacent. The population of new Delhi was now something over 30,000, the majority being workmen and their dependants. The centre of the new city, the parliament house, is four miles from the famous Kashmir Gate. Lord Hardinge told a picturesque story of how, while the site was being discussed, he rode out to the Raisina Hill, from which he saw the wonderful panorama of old Delhi—the domes and the minarets of Jama Masjid, the rose-coloured sandstone of Humayun's

tomb, Safdar Jang's mausoleum, and other superb buildings, with the Jumna, like a streak of silver, in the foreground. It was a wonderful vision, and he said at once that the top of the hill must be the site of Government House. But the top of the hill was a restricted space for the residence of a viceroy and his staff. The Indian engineer, however, proved equal to the occasion; he sliced off the top of the hill, and formed a plateau for Government House and secretariats, from which the city of Shah Jehan will be visible, to remind the British rulers of India's mighty past, even as Sir Edwin Lutyens's buildings, it is to be hoped, will embody Indian unity and the traditional colonial policy of Britain. One of the architects of Delhi, Mr. Herbert Baker, stated that the climate is tolerable for only seven months of the year. Sir Hugh Keeling took exception to this, and said that only from about the third week in May to the end of July is the really uncomfortable time in new Delhi. He himself during thirteen years had never been away from the place except during June and July, and he had done eight or nine hours' work a day without experiencing any damage to his health or any personal discomfort. He predicted that the new Delhi would be the headquarters of the Government of India all the year round, with the exception of the two central months, when the Government would camp at Simla.

CLAIMS IN RESPECT OF MINER'S PHTHISIS.

WE have received a copy of the recommendations of the Miners' Phthisis Medical Bureau of Johannesburg, of which Dr. W. Watkins-Pitchford is chairman, with regard to the character of the medical evidence in support of claims for benefits by miners or the dependants of deceased miners. The matter is of some general interest, since medical practitioners in Great Britain are not infrequently called upon to give certificates of the present health, or the cause of death, of men who have previously worked as miners in the Transvaal. The Medical Bureau of Johannesburg is often required to adjudicate upon claims for benefit based upon the assertion that a miner is suffering from, or has died from, silicosis or tuberculosis, and in the absence of definite medical particulars the bureau and the claimants are at a considerable disadvantage. An accurate description of the signs and symptoms observed during the illness of the miner is of great value, but cannot by itself be taken as conclusive evidence of the exact cause of the illness or death. It is, for example, impossible in most cases to detect clinically the existence of an underlying silicosis in the presence of extensive tuberculosis. The Medical Bureau, therefore, asks that the following steps should be taken by medical practitioners in attendance on miners seriously affected with miner's phthisis, or other diseases to which silicosis is believed to predispose or contribute. The sputum should be examined for tubercle bacilli by experts, repeatedly if necessary, and the certificates sent to the bureau should state definitely that the sputum was expectorated in the presence of the medical practitioner. If the miner is resident in the Witwatersrand area he should be examined during life by the bureau clinically, bacteriologically, and radiologically. In many cases the foregoing procedures will enable the bureau to place the miner in the pensionable stage of miner's phthisis during life, and thus secure his position and that of his dependants. In the case of a miner resident outside the Witwatersrand area who has not previously been registered by the bureau as suffering from silicosis or tuberculosis, a good instantaneous x-ray negative of the chest should be obtained and certified by the radiographer as being that of the miner in question. Such a negative usually affords conclusive evidence of silicosis, and may indicate also the presence of tuberculosis. In the event

of death in cases in which these steps have not been taken, or the results have been inconclusive, it is suggested that the exact condition of the lungs should be determined at a necropsy by an expert pathologist, preferably attached to some public institution. If the examination is made within the Union of South Africa the Miners' Phthisis Act, 1925, requires that the lungs should be forwarded to the bureau for examination. In cases outside the Union the lungs, certified by the medical practitioner as being those of the miner, should be examined by an expert pathologist, whose detailed report should be sent to the bureau. A necropsy is not necessary when silicosis has been already certified by the bureau, or definitely revealed by an x-ray examination during life, and in which, in addition, proof of the presence of tubercle bacilli in the sputum has been obtained. In all other cases a necropsy is recommended, since it is often the only means of deciding whether a slight degree of silicosis, previously incapable of being detected, is associated with tuberculosis. The evidence afforded by such an examination may, therefore, be of decisive importance in a claim by the dependants of the deceased miner.

FIFTEENTH CENTURY FRENCH TRACTS ON THE PLAGUE.

A WORK entitled *Remedies against the Plague*,¹ recently published under the editorship of Dr. A. C. Klebs of Noyon and Mlle E. Droz of Paris, is the first volume of the Scientific Documents of the XVth Century, a collection which will comprise a series of portfolios relating to medicine, astronomy, eheirromancy, surgery, natural science, mathematics, and pedagogy, and will appear simultaneously in English and French in an edition limited to 500 copies of each work. The present volume contains within its beautifully printed covers five facsimiles of the earliest French tracts on plague printed in the fifteenth century, followed by historical notes by Mlle Droz, and a list of all the incunabula on plague (130 in number) compiled by Dr. Klebs. The first facsimile is that of a poem entitled "Le Regime de l'Epidemie et remede contre icello," by Jean Jasme, otherwise known as Johannes Jacobi, chancellor of the University of Montpellier, and contemporary of the more famous Guy de Chauliac. The poem, which is incomplete, consists of ninety stanzas of ten octosyllabic lines describing in a pedestrian strain the causes, symptoms, prevention, and treatment of plague. The editors have discovered in the Bibliothèque Nationale at Paris a second manuscript of the poem containing the missing strophes, from which we learn, not only the name of the author, but also that it was written in the year 1357 and read before the clergy at Montpellier. The second and third facsimiles are taken from the "Remede tresutile contre fièvre pestilencieuse," which is a translation of Jacobi's "Tractatus pestilentiae." The safeguards against plague recommended are simple living, moderation in food and drink, avoidance of crowds, frequent washing of the hands with water and vinegar, and airing and disinfection of the house. The remedies include drugs, diet, spiritual consolation, blood-letting, and evacuation of the buboes. The fourth facsimile is that of the title and colophon of "Le Regime contro epidemie et pestilence" of Thomas Le Forestier of Arranches, who was the first to describe the sudor Angliens which broke out in London in 1485; and the fifth facsimile is from the "Regime contre la pestilence" written by several Bâle physicians, and printed at Lyons by Claude Nourry about the year 1519. Dr. Klebs and Mlle Droz are to be warmly congratulated on the production of this work, which will be of interest to every medical historian and prove indispensable to the student of the medical literature of the fifteenth century.

¹ *Remedies against the Plague*. The earliest French tracts printed in the fifteenth century. Facsimiles, notes, and lists of all the incunabula on Plague. Paris: E. Droz, 1925. (9½ x 7½, pp. 56. 100 fr.)

AUTO-EXPERIMENTERS.

MEDICINE has been described as a noble profession but as, not to put it lower, a disastrously bad trade; some might regard it as also a dangerous trade, for the worry, hurry, and scurry over meals favour the incidence of angina pectoris, which has been called "the doctor's disease," and of duodenal ulcer. In addition the exposure to infection may well play a part in making the average duration of life among the healers of bodily ills so much less than that of those who save souls. In an interesting article on "Men who have experimented on themselves" Professor Fraser Harris¹ touches on the risks which those who fight disease take in the day's work, just as the sailor and soldier do, and recalls the days before the discovery of antidiphtherial serum, when the expulsion of mucus and membrane at the then frequent tracheotomies might infect the saviour of the child's life. He goes on to relate instances of impaired vision from prolonged microscopical work, from the time of the young Dutchman Jan Swammordam down to a friend of his own who suffered for his energy in search of the spirochaete soon after Schaudinn's announcement of his discovery. He refers to Dr. J. S. Haldane's and Professor Joseph Barcroft's self-sacrifice in connexion with carbon monoxide and diminished oxygen pressure, to Professor Leonard Hill and his students sitting in such a stagnant atmosphere that cigarettes would not light, and to Chittenden's minimum protein dietary. He also refers to a most distinguished neurologist whose name is left blank, and is stated to have "cut his own ulnar nerve at the elbow and observed the phenomena for himself"; this has some resemblance to "A human experiment in nerve division," giving the observations made with the late Dr. Rivers on the sensory phenomena following division of the radial and external cutaneous nerves in Dr. Henry Head's left arm on April 25th, 1903. To the well known story of Sir James Y. Simpson's experiments with chloroform he adds an account of the butler's enthusiastic administration of the new anaesthetic in "a rich guid willie-waught" of champagne to the cook, who in a few moments was prostrated on the kitchen floor, and his advice to his master: "Stick to the chlory, Sir James, stick to the chlory."

Dr. A. J. CLARK, professor of pharmacology at University College, London, has been appointed to succeed the late Professor Cushny at Edinburgh. Professor Clark is a graduate of Cambridge (M.B. 1910, M.D. 1914), and received his medical education at St. Bartholomew's Hospital. After serving as lecturer on pharmacology at Guy's Hospital, he was appointed professor of pharmacology in the University of Capetown; from there he was translated to University College, London. He is the author of a work on *Applied Pharmacology*, and of numerous contributions to the *Journal of Physiology* and other scientific periodicals. He served during the war, and received the Military Cross. It is expected that he will take up the duties of the chair in Edinburgh next October.

WE regret to have to record the sudden and unexpected death of Dr. E. H. Bradford of Boston, Massachusetts, one of the pioneers of orthopaedic surgery in Boston, and author, with the late R. W. Lovett, of *Orthopedic Surgery*, a standard textbook of the subject. He had retired from practice some time ago.

WE much regret to announce the death of Dr. E. S. Reynolds, Emeritus Professor of Clinical Medicine in the University of Manchester, and consulting physician to the Manchester Royal Infirmary. A memoir will appear in an early issue.

Union of South Africa.

[FROM OUR CORRESPONDENT IN CAPE TOWN.]

PROPOSED NEW GENERAL HOSPITAL, CAPE TOWN.

A controversy has been raging as to which of two sites should be selected for the new general hospital. At a fully attended meeting of the medical profession, held in September, 1923, it was decided unanimously to press for the site at Groot Schuur, on the estate of the late Cecil Rhodes. Within the last few months an alternative site, on what is known locally as Hare's Brick Fields, Salt River, has been recommended by Dr. Robert Sharp. At a meeting of the public, convened by Dr. Sharp, and held in the library of the City Hall on the evening of April 1st, 1926, the pros and cons of the respective sites were argued by various speakers, prominent among whom were Sir Carruthers Beattie, Principal of the University of Cape town, Dr. Sharp, Dr. H. A. Moffat, and Mr. F. K. Wiener. The mayor, Mr. F. W. Fish, was in the chair. The following resolution was eventually adopted by an overwhelming majority:

That this meeting of Capetown citizens urges the Hospital Board to proceed with all dispatch with the building of the hospital on the Groot Schuur site.

On the following Tuesday, April 6th, a special meeting of the Western Branch of the British Medical Association was held to sound the opinion of the profession, and after a debate, which was maintained at a very high level, a resolution in favour of the Groot Schuur site was adopted by 57 votes to 1. On the following day the Cape Hospital Board finally committed itself to the Groot Schuur scheme by 20 votes to 6. Notwithstanding organized opposition on the part of a section of the public which may be anticipated, it is hoped that at last a new general hospital, worthy of the mother city, will soon become an accomplished fact.

DR. REITH FRASER.

Very widespread sympathy has been extended to Dr. A. Reith Fraser, lecturer on venereal diseases at the University of Capetown, on the occasion of his recent illness. For the past four years Dr. Fraser has acted as honorary secretary of the Western Branch of the British Medical Association, and it is almost entirely due to his tireless energy, to his extraordinary talent for organization, and to his personal charm of manner and tact, that the Branch finds itself in a most flourishing condition, with a membership exceeding 230. Acting on medical advice, Dr. Fraser has relinquished—only temporarily it is hoped—his secretarial duties. His many friends, both within the profession and without, wish him a speedy return to health.

AN HISTORIC PUBLICATION.

There has been presented recently to the library of the local Branch of the British Medical Association a copy of the first medical journal to be published in South Africa. This is the gift of Mr. Walter Floyd, dental surgeon, of Capetown. The full title is the *Capetown Medical Gazette*, or *Journal of the Medical Sciences*; it was edited by the late Dr. H. A. Ebdon, and published by Messrs. Pike and Philip, St. George's Street, Capetown. The presentation consists of four paper-covered quarterly parts, constituting vol. i. The date of its appearance was January, 1847, and the price per part is given as one shilling and sixpence. It is not known whether any other copies exist. It is fitting that this landmark in the history of South African medicine should find a home in the library of the oldest established medical organization in the country. Prominent features in the *Gazette* are a letter from a correspondent, urging the establishment of a lectureship in chemistry, probably the first attempt to plant the seeds of a medical school in South Africa (p. 15); a reference to the proposal to form a medical society in Capetown (p. 32); a letter urging the State licensing of midwives (p. 63), of more than passing interest at the present moment, in view of the fact that legislation dealing with this matter is now before Parliament; and a plea for the development of the Cape as a sanatorium for invalids from India (p. 82). In his introductory remarks contained in the first number

the editor writes, "In Capetown itself difficulties have also long obtained as regards the social relations of the members of our profession, many of whom, although inhabiting the same town, are virtually as little known to each other as if separated by the sandy wastes and mountain barriers of the interior. This injurious state of feeling has been fomented and perpetuated by a combination of unfortunate circumstances, dividing into discordant sections a body of men whom the common weal, not less than their own individual interests, ought to maintain in harmony and friendship."

VISIT OF THE MEDICAL SECRETARY OF THE BRITISH MEDICAL ASSOCIATION.

When, on the conclusion of his tour through South Africa, Dr. Alfred Cox sailed from Capetown, on Friday, March 26th, he took with him the best wishes of a wide circle of friends in the Cape Peninsula. That his visit is to bear fruit, and that abundantly, is a foregone conclusion, but it behoves every individual member of the British Medical Association to do his or her utmost to bring about that solidarity in the profession which he preached so assiduously. The fusion of the two contending medical organizations, happily brought about, will be a monument to the magnitude of the task he has successfully completed. In the area of the Western Branch of the British Medical Association steps are already being taken to inquire into the feasibility of forming Divisions on the lines suggested in his report to the South African Committee. There are many who will look forward with pleasure to renewing acquaintance with Dr. Cox on future visits to the Old Country.

England and Wales.

THE BARTLET CONVALESCENT HOME, FELIXSTOWE.

THE official opening of the Bartlet Convalescent Home at Felixstowe, by Sir Arthur Churchman, M.P., an ex-president of the East Suffolk and Ipswich Hospital, on May 20th, is the latest link in the chain of medical service which began in 1836, when the father of the late Dr. J. H. Bartlet was appointed the first member of the honorary staff of the hospital on its establishment. Dr. J. H. Bartlet, who died in 1917, devoted himself during his life to the improvement of the hospital, and one of his most earnest desires was to provide a convalescent home for its patients. He bequeathed about £200,000 for this purpose, and additional sums, amounting to £30,000, were received from other sources. The purchase of the land and the building of the home cost over £90,000, leaving a balance for investment for the maintenance of the home. The building, which was fully described and illustrated in the *East Anglian Daily Times* (May 21st), is self-contained and under one roof, though divided into three distinct portions—the administrative block, the convalescents' dining hall (a large room with a barrel vaulted ceiling), and the ward block, facing south, and so placed as to secure the greatest amount of sunshine and shelter from the wind. The four wards in this block will accommodate about sixty patients; the ventilation, lighting, and other arrangements are of the most modern type, and the comfort of patients has been considered in every respect. In the grounds undulating paths with easy gradients enable them to leave the wards in wheeled chairs, pass through balconies, and travel through the gardens. Eight shelters have been constructed so that patients can sit out of doors in all states of the weather. Dr. J. H. Bartlet, whose generosity has thus presented to the East Suffolk and Ipswich Hospital so valuable an extension, was a fellow student of the late Lord Lister, and when surgeon to the Ipswich Hospital was one of the earliest exponents of antiseptic methods in this country. He was a J.P. of the borough of Ipswich and mayor in 1894-5, when the British Association paid its second visit to the borough. Dr. Bartlet's grandfather began medical practice in Ipswich in the first decade of last century, so the local medical connexion of this family is of unusually long duration.

NOTTINGHAM CHILDREN'S HOSPITAL.

A satisfactory feature of the annual report for 1925 of the Nottingham Children's Hospital is the continued increase of subscriptions, which has resulted in there being a balance of £230 on last year's working. It was stated at the annual meeting on May 18th that when the new wing was completed it would nearly double the accommodation for patients, and a materially increased income would be required, but it was believed that the progressive policy of the hospital would be generally approved and supported. In consequence of some difficulties that have been experienced, it would not be possible to complete the new wing in time for the Annual Meeting of the British Medical Association, as had been previously hoped. During the past year a considerable increase in treatment by ultra-violet rays had been possible, and a new lamp had been given to the hospital. Owing to the necessity of closing the Portland Ward three times on account of infectious disease, the admission of urgent cases had been considerably delayed, and the figures of the annual report reduced. The total number of new out-patients was 6,458, and of in-patients 666. In the heliotherapy department 286 patients had been dealt with, the average number of attendances each month being 2,232. The old x-ray apparatus was now inadequate, and a new outfit was to be provided when the out-patient department had been completed.

BIRMINGHAM HOSPITAL SATURDAY FUND.

Sir David Brooks, chairman of the Birmingham Hospital Saturday Fund, announced at its annual meeting that since its inception fifty-three years ago over £1,000,000 had been collected by the fund in aid of the city hospitals. The total subscriptions last year amounted to £62,126, which was £4,366 in excess of the subscriptions during the previous year; this money had been paid in voluntarily by the workpeople of the city. Last year an effort had been made to raise the weekly subscriptions from 1d. to 2d.; many subscribers had responded, but there were others who had not yet been able to increase their donations. The chairman hoped, however, that before very long it would be possible to raise in this way an annual sum of £100,000. The convalescent homes had been hampered by a debt of £20,000, and a special appeal had therefore been made for an additional 1d. a week for half a year. As a result of that effort, aided by other donations, about half the debt had already been paid off. In Birmingham there was a smaller number of beds in proportion to the population than in any of the other large cities of the kingdom. The chairman appealed, therefore, for an increased effort to provide the additional accommodation that was required. He said that new buildings on the outskirts of the city would be preferable to extension of those in the central area. A complete scheme of hospital treatment in the city ought soon to be established, so that a greater economy in treatment might be obtained by providing more hospitals for special diseases in which prolonged treatment was required.

LUNACY IN LONDON.

The Mental Hospitals Committee of the London County Council reported on April 27th the annual returns of insane persons for whose accommodation the Council is responsible. On January 1st the number (excluding insane patients in the institutions of the Metropolitan Asylums Board and in Poor Law guardians' institutions and those boarded out with relatives and friends) was 19,308 (7,960 males and 11,348 females), an increase of 181 males and 67 females during the year. Of this number, 18,790 are in the London county mental hospitals—17,558 of them as rate-aided patients, the remainder on the private list, with the exception of 13 chargeable to the Prison Commissioners. In addition to the patients for whom the Council is directly responsible there were, on January 1st, 156 insane persons resident in Poor Law guardians' institutions, 89 boarded out by boards of guardians, and 4,975 chronic harmless patients accommodated in the Metropolitan Asylums Board's institutions (excluding cases dealt with under the Mental Deficiency Act). The number of chronic lunatics accommodated by the board is the lowest recorded

since 1890. The total number of insane persons chargeable to the London rates, together with criminal lunatics and private patients in the county mental hospitals, was 24,528 on January 1st, as compared with 24,330 on the corresponding date in 1925.

Scotland.

EDINBURGH MEDICAL STUDENTS AND THE STRIKE.

DURING the general strike a large number of students attending the University took the places of men on strike in matters such as driving trams, occupying posts on the railway, in power-houses, and other places for which their special knowledge or technical training eminently fitted them. In view of the fact that they were doing work of national importance, they were freed by the University from attendance on their classes and from any prejudice which they might suffer by inability to take part in examinations. So successfully did they carry out the work which they undertook to do that at a meeting of the board of managers of the Royal Infirmary, Edinburgh, held on May 17th, it was reported that seven letters had been received from strike committees and trade unions protesting against what was characterized as "black-legging" by university students during the general strike, and threatening in retaliation the withdrawal of workers' contributions to the infirmary. It was pointed out by Sheriff G. L. Crole, one of the managers, that the board had no jurisdiction over the students, and it was suggested that the unions should receive a reply to that effect. Sir Malcolm Smith, who presided, said that he thought the letters had been written under a misapprehension. It was suggested by one manager that the board should voice its sympathy with the trades council and other similar bodies; but the chairman, in reply, pointed out that to begin to express sympathy for one or other side was a very delicate thing for such an institution to do, and it was agreed that replies should be sent to the effect that the board had no jurisdiction over the medical students. This action of strike committees seems to be part of the general policy, for a similar letter was addressed to Guy's Hospital and received a similar reply.

That the action of the Edinburgh students is regarded in a different light by other observers is shown by a letter the Principal of the University has received from Mr. Thomas Cowan (shipowner), who has, before this, shown himself in various ways a generous supporter of public institutions in Edinburgh and Leith. His letter to the Principal was as follows:

"As convener of the Emergency Committee of the Leith Dock Commission, which dealt with the exceptional circumstances arising out of the general strike, I am greatly impressed by the enthusiasm, the initiative, and the working capacity of the 270 students who gave their much valued assistance in relieving the congestion of dock traffic. They worked splendidly, and demonstrated afresh the grit and pluck of our university youths. Personally I would like greatly to show my appreciation of their splendid efforts in the great recent national emergency, involving the very basis of constitutional government, and to this end I enclose you a cheque for £10,000 for the general purposes of the university."

CENTRAL MIDWIVES BOARD FOR SCOTLAND.

The examination of the Central Midwives Board for Scotland, held simultaneously in Edinburgh, Glasgow, Dundee, and Aberdeen, has just concluded with the following results: Out of 148 candidates who appeared for the examination, 134 passed. Of the successful candidates, 18 were trained at the Royal Maternity Hospital, Edinburgh, 40 at the Royal Maternity Hospital, Glasgow, 6 at the Maternity Hospital, Aberdeen, 15 at the Maternity Hospital, Dundee, 13 at the Queen Victoria Jubilee Institute, Edinburgh, and the remainder at various recognized institutions.

HOME RELIEF OF INCURABLES.

The annual meeting of the Royal Society for Home Relief of Incurables was held in the Council Chambers, Edinburgh, on May 11th. Lord Provost Sir William Sleight,

who presided, said that this society needed all the encouragement that the city could give. Its work had been very successful during the past year. The society aimed at making small grants to a large number of people who were struggling with adverse conditions arising from ill health. The amount paid to annuitants during the year in grants of £10 had been £4,863. The Dunlop Cancer Fund, which was administered by this society, paid to annuitants grants of £16 a year, and the amount thus paid out had been £1,598. Unfortunately, very few of the sufferers from the malady with which this fund dealt lived to receive the full year's annuity. The society had now been carrying on this excellent work for over 120 years, and it was well supported by the generosity of the public, which he hoped would continue, so that the directors might be enabled to provide for the many appeals for assistance which they received.

GLASGOW RED CROSS SOCIETY.

Colonel Adington, county director of the City of Glasgow Detachment of the Scottish Branch of the British Red Cross Society, presided, on May 5th, at the annual general meeting of this branch. In reviewing the work of the Glasgow detachment, the county director stated that the effect of the natural inactivity which followed the termination of the war-time increase in work was still to be seen. Those members, he said, who had done excellent work during the war had not the same incentive now to continue training, and also the opportunities for practical work were few in number. The training of the individual was now, therefore, not so advanced as it might be, and commandants had great difficulties, which they were doing their best to overcome. With a renewed supply of keen probationers it was hoped that the existing difficulties would in time be overcome, and that new detachments would be formed.

NEW WEST OF SCOTLAND HOSPITAL.

At the monthly meeting of the Dumbarton Town Council held on May 16th, Provost Garrick presiding, a report was submitted regarding the joint small-pox hospital to be erected at Duntocher at a cost of £12,000. Of this sum, £6,000 is to be paid by the corporation of Glasgow, and £6,000 by the combined local authorities in Dumbartonshire. Each authority will pay for the treatment of its own cases. The hospital is to have sixteen beds, but the foundations of an emergency ward of fourteen beds will be laid. The scheme is smaller than was at first thought necessary; the city of Glasgow only comes into it as the port authority for cases of small-pox arising on the River Clyde.

Ireland.

VITAL STATISTICS FOR NORTHERN IRELAND.

During the quarter ending March 31st, 1926, 7,062 births were registered in the twenty-seven superintendent registrars' districts in Northern Ireland, equivalent to an annual birth rate of 22.1 per 1,000 of the estimated population, as compared with the corresponding figures of 18.2 for England and Wales and 21.6 for Scotland. The deaths registered during the quarter numbered 5,299, representing an annual rate of 16.6 per 1,000, as compared with 13.6 for England and Wales and 14.8 for Scotland. The birth rate was 0.7 above that for the corresponding quarter of 1925, and 0.4 below the average rate for the first quarters of the ten years 1916-25. The death rate was 3 below that for the corresponding quarter of 1925, and 3.6 below the average rate for the first quarter of the previous ten years. Of the deaths registered 18.6 per cent. occurred in public institutions, and 10.5 per cent. of the total deaths registered were uncertified, there having been neither a medical attendant during the last illness nor an inquest held by a coroner. The number of successful primary vaccinations registered in Northern Ireland during the quarter under review was 5,359. The birth rate for county boroughs and urban districts (which contain nearly one-half of the total population for Northern Ireland) was

27.1 per 1,000 of the population; the birth rate for the remainder of Northern Ireland was 18.5 per 1,000. The death rate for the county boroughs and urban districts was 17.7 per 1,000, and for the remainder of Northern Ireland 16.3.

ULSTER MEDICAL SOCIETY.

The annual meeting of the Ulster Medical Society was held in the Medical Institute, Belfast, on May 13th. The president, Mr. James A. Craig, F.R.C.S., occupied the chair. The report of council showed a very full and successful winter's session; it recommended the purchase of an epidiascope, and some renovations in the building. The report, which stated that there were 189 fellows and 67 members, was adopted unanimously. The honorary treasurer's report showed a credit balance of £394. The following officers were elected for the ensuing session: President, Dr. M. J. Nolan, resident medical superintendent of the Down District Asylum; vice-presidents, Mr. P. T. Crymble, F.R.C.S., and Dr. J. C. Loughridge; honorary treasurer, Dr. J. T. Lewis; honorary secretary, Dr. R. M. Beath; honorary editing secretary, Dr. J. A. Smyth; honorary librarian, Dr. W. L. Storey; Council, Drs. R. Marshall, G. G. Lyttle, R. J. Johnstone, M.P., P. E. O'Flaherty, W. Burns, and J. W. Peatt.

MEMORIAL TO DR. H. J. BOYD AND HIS WIFE.

A beautiful and dignified memorial in the form of a high-gate has been erected at the entrance of the ground of the historic church at Hillsborough by the numerous friends of the late Dr. Henry J. Boyd, who had been forty years medical officer of the dispensary, and of his wife. The gate, which is of solid oak and red tiled, was dedicated on May 15th by the Lord Bishop of the Diocese. In addition to numerous friends and parishioners a large number of medical men were present. Dr. Boyd had been on the select vestry for forty years, and had held all the lay offices of the parish. Mrs. Boyd was one of the founders of the Hillsborough Sick Nursing Society and of the local branch of the Child Welfare Society.

Correspondence.

THE UNIVERSITY OF LONDON.

SIR,—In your editorial with this title you say: "Our information is that medical opinion in the University is not in accord with that now expressed by the Senate and by Convocation" (which have passed resolutions rejecting the Majority Report of the Departmental Committee). "... We understand that the Board of the Faculty of Medicine, the Committee of Medical Members of the Senate, and the Board of Advanced Medical Studies have given definite expressions to their views in favour of the recommendations in the Majority Report of the Departmental Committee."

May I point out that the sole body which has authority to speak for "medical opinion in the University" is the Faculty of Medicine itself, and the Faculty has not as yet been consulted in the matter. The "Committee of Medical Members of the Senate" has no statutory or constitutional sanction. The "Board of the Faculty" derives its authority wholly from the Faculty; its function is to prepare a case for the consideration of the Faculty, which alone can decide any medical issue. Until the Faculty has pronounced its decision no other body whatsoever has any constitutional sanction to express an opinion for it.

When the Haldane Report came out in 1913 the procedure adopted was very different from the irregular action which has now been taken by the bodies which you name. In 1913 the Board of the Faculty of Medicine held something like twenty-four meetings to discuss that Report. It drew up a reasoned statement, which was finally submitted to the Faculty, and which was not published until the Faculty had considered and confirmed it at a large meeting called for the purpose. All the meetings of the three bodies which you name were called during the

recent strike. The meeting of the Committee of Medical Members on May 5th was attended by four persons, three surgeons—members of the Council of the Royal College of Surgeons (the most cliquy and unrepresentative body probably in existence)—and one physician. The three surgeons supported the Majority Report; the physician did not vote. The three surgeons have as little right to speak for the Faculty of Medicine, which numbers over 500, as the three tailors of Tooley Street had the right to speak for the "People of England" on a certain famous occasion.

The meeting of the Board of the Faculty of Medicine (held the day after the meeting of the above committee) was attended by only eight persons, including the surgeons who had spoken for the Committee of Medical Members. The vote even of this small meeting was not unanimous; the Report of the Departmental Committee was a mere item in a long agenda; it was entirely impossible in the very short time at the disposal of the meeting to discuss the report in any detail. The action taken by the Board of the Faculty on this occasion was unconstitutional, and contrasts very unfavourably with the action, described above, taken by the Board in 1913.

The meeting of the Advanced Board was again a very small meeting. It comprised the same ubiquitous surgeons already mentioned, who flit across the boards like the supers who vainly endeavour to represent an army on the stage of a small provincial theatre, the same persons crossing the footlights several times in succession. The impression which your remarks give that these three bodies speak for the medical profession or for the Faculty of Medicine of the University of London is, I submit, an erroneous one.

Your statement that "colleges and constituent units of the University have no direct representation on the present Senate" is incorrect. The two largest colleges of the University—University College and King's College—have sent four representatives, directly elected by these colleges, to the Senate for the last twenty-six years. Those members who have sat upon the Senate, as I have, for the past twenty years can testify to the inconvenience of direct representation of colleges. There have been two "bloes," consisting of representatives and supporters of these colleges, which by their feuds and intrigues have materially added to the difficulties of conducting the business of the Senate.

Your editorial complains that the medical representation on the present Senate, which is the supreme governing body, is "only a small minority" (one-sixth) of that body. Since you hold these views it is surely inconsistent that you should support the Majority Report, for this eliminates all medical representation from the supreme Council, and even cuts down the statutory representation on the new Senate (which becomes a merely advisory body, without any real power) from one-sixth to one-seventh. As a matter of fact the present Senate has a medical representation of one-fifth, because certain other than medical bodies have elected members who are medical men. For these reasons I find it difficult to understand how any instructed medical opinion can support the Majority Report.

I think that your editorial is again a little biased in its presentation of the case of the medical schools. You record the decisions of St. Bartholomew's and Guy's Hospitals, which support the Majority Report, but you omit the decisions of the London Hospital and St. George's Hospital, both of which were reported to the Senate at the same time as the decisions from Guy's and St. Bartholomew's, as objecting to the Majority Report. Your information would appear to have been rather carefully selected, and does not seem to include all the facts. Only four of the twelve medical schools have so far submitted any opinion on the Departmental Committee's Report; of these four two want, and two do not want, the Majority Report; and there seems as little foundation for the opinion expressed by your editorial that the medical schools are preponderantly in favour of the Majority Report as there is for the suggestion that the Faculty of Medicine of the University is in agreement with that Report.—I am, etc.,

London, May 24th.

E. GRAHAM LITTLE.

SIR,—Those who wish to see the University of London developing into a co-ordinated group of schools and colleges engaged in the diffusion and advancement of knowledge will welcome the attention you have drawn to the report of the Departmental Committee, whether they agree or disagree with your conclusions.

The recommendations of the Committee, if carried into effect, will have a most profound influence upon the medical schools and upon the Faculty of Medicine, and it seems particularly unfortunate that neither the schools nor the Faculty of Medicine have been given either time or opportunity for the adequate consideration of the proposals. My own school received a letter from the Senate on April 27th requesting that comments upon the report might be submitted in time for the consideration of the Senate at its meeting on May 10th or 11th. The members of the Board of the Faculty of Medicine received copies of the report on April 30th, the Board met on May 4th, the first day of the strike, and the attendance was very small. The consideration of the report was one item of a long agenda, but the Dean stated that it was necessary to arrive at a decision on that day.

In these circumstances and without debate the report was approved by a majority. The Committee of Medical Members of the Senate is a body which in recent years has usurped unconstitutionally the functions of the Board of the Faculty of Medicine, and its opinion cannot be accepted as necessarily representing the opinion of the Faculty.

The opinion of the Faculty was not taken by the Departmental Committee, nor was the Faculty asked whether it wished to modify the considered report upon the proposals of the Haldane Commission, which it prepared with great labour in 1913 and 1914, and presented to the Senate in the latter year with a request that it might be submitted to the Board of Education. That this report was not considered by the Departmental Committee is obvious from Section 8 of its report, in which it states that no responsible body desired to give evidence in favour of modification of the existing system of admitting external students to the examinations for university degrees, though in 1914 the Faculty of Medicine expressed strongly its opinion that degrees in medicine should be granted only to those who had spent at least three years of their professional education at some school of the University. There are many other points in the report which show that the Departmental Committee was not in possession of the considered opinion of the Faculty delivered on the last occasion when it was allowed the statutory rights of discussion.

The object of this letter is to urge that the Faculty of Medicine, aided by its board, should be invited to prepare a considered opinion upon the report of the Departmental Committee in so far as the proposed changes seem to affect for good or ill its academic interests. The Faculty may be willing to accept Fascist principles and to hand itself over to the control of an autocratic Principal and financial council without academic interests, and a Senate without the power of the purse; but an opportunity for debate should be afforded.

The medical schools may be trusted to look after their own interests, but I should like to point out that the Government grant for the technical instruction of medical students concerns a large number of students who are not undergraduate members of the London University. The Departmental Committee did not seem to appreciate this point when it stated that the present system of distribution of the grant by a committee of the Treasury is entirely indefensible.

The Departmental Committee suggests that the medical schools should surrender to the University not merely the control of a large part of their income but also a considerable measure of their autonomy, yet does not suggest any noteworthy advantages in return; it does not propose any system whereby the majority of the students might become undergraduates, or offer to reserve the London degree for those who have been educated in London, and scorns the suggestion that the schools should be incorporated in the University.

Surely, Sir, discussion is desirable.—I am, etc.,

London, W.1, May 24th.

CECIL WALL.

FATAL HAEMORRHAGE FROM THE LIVER IN AN
INFANT FIVE DAYS OLD.

SIR,—Mr. J. Allan Berry (p. 825) will find in a paper I wrote thirty-five years ago,¹ on visceral haemorrhages in stillborn children, notes of 37 cases of hepatic haemorrhage: of these, 24 were on the upper surface, 8 on the lower surface, 3 on both surfaces, and 2 at the posterior edge. In one case the blood had burst through the capsule into the peritoneum. In another case (hydrocephalus) strong traction had been made and the liver was ruptured with free haemorrhage into the peritoneum. In the paper mentioned I have also noted rupture and haemorrhage from the suprarenals in three cases. The injuries are illustrated by coloured drawings. Mr. Allan Berry's case is especially interesting in that it points to the large size of the child (10 lb.) as a factor in the causation of these haemorrhages, and particularly because the child was delivered by the natural forces and survived for five days.—I am, etc.,

London, W.1, May 19th.

HERBERT R. SPENCER.

THE ETIOLOGY OF ACCIDENTAL HAEMORRHAGE.

SIR,—The work of Dr. F. J. Browne (BRITISH MEDICAL JOURNAL, April 17th, p. 683) supports the modern opinion that the toxæmias of pregnancy are caused by a preceding primary toxæmia; but there is much against this view. In respect of accidental haemorrhage, Dr. Browne admits that "in some cases" a definite history of trauma can be obtained; but he pushes trauma aside as "probably coincidental." He believes that nephritis is necessary, that this produces toxæmia, and the toxæmia the bleeding. The bleeding is "caused by endogenous poisons held up in the circulation by the acutely damaged kidney."

But according to FitzGibbon² certain cases of accidental haemorrhage occur without nephritis. Nephritis is only prominent in those cases in which the bleeding is largely concealed and in which the badly termed "apoplexy" of the uterus occurs. But FitzGibbon did not see that the distension of the uterus (by the bleeding) compresses the kidneys and causes the "nephritis" or its exaggeration. Thus, in some cases, albuminuria has been absent with the onset of the bleeding, but present later.³ Dr. Browne, however, easily gets over this difficulty: he lays stress on the absence of albuminuria in nephritis; we cannot depend (he says) on the presence or absence of albumin in the urine; we must use other tests. But it has been denied that in the toxæmias of pregnancy the blood picture, as regards non-protein nitrogen, is changed⁴; and that eclampsia is due to a rise of endogenous poisons in the blood from faulty visceral action.

"Nephritis," certainly, predisposes to accidental haemorrhage—but by determining a rise of systemic blood pressure. This tends to rupture placental sinuses, but their integrity is conserved by the intra-amniotic pressure which, during uterine relaxations, depends on the tonicity of the abdominal wall and diaphragm. Thus in primigravidae, in whom the abdominal wall and diaphragm are in better condition than in pregnant multiparae, even when a state of "nephritis" exists (as in pre-eclampsia), accidental haemorrhage is less likely and occurs less often than in the pregnant woman already the mother of many children.

The predilection of eclampsia for primigravidae and of accidental haemorrhage for pregnant multiparae seems to suggest that both are due to the same cause (as you observe); not, however, to a toxæmia, but to a pressure. In the one, the increased intra-abdominal pressure, the average of which is raised by profoundly disturbing the renal and hepatic function, produces toxæmia; in the other, in which the average intra-abdominal pressure (perhaps) is not raised, but in which excursions due to activity occur, the latter, by rupturing mechanically

placental sinuses, leads to accidental haemorrhage. When the blood cannot sufficiently escape from the uterus, the organ distends and is only prevented from bursting by the resistance of the abdominal wall and diaphragm, the tonicity of which with progressive distension of the abdomen is increased. The increased intrauterine pressure causes the changes in the uterine wall (haemorrhages and necrosis); the increased extrauterine (but intra-abdominal) pressure causes the viscera to be unduly compressed. Hence the same changes occur in these viscera as in straightforward pre-eclampsia with the rise of toxæmia and even convulsions.

The changes in the urinary bladder in cases of persistent retroversion of the gravid uterus support my opinion. Here we have a toxæmia, and a change in the bladder wall—even to its necrosis. That this change is produced mechanically will be admitted; the passage of a catheter and the rectification of the uterine position in the early stages stops the process—just as escape of blood, preventing the uterine distension in accidental haemorrhage (however it cause a grave anaemia), prevents not only the change in the uterine wall (extravasation of blood plus necrosis), but also the rise or exaggeration of visceral change. In accidental haemorrhage the changes in the uterine wall are produced mechanically, just as are the changes in the bladder wall in the case mentioned. In the latter there is no question of the play of a preceding or associated toxæmia. Similarly, in accidental haemorrhage there is no reason to posit the rise and play of a preceding toxæmia.

There is, indeed, reason to discredit the effect of "nephritis." When women with nephritis become pregnant they more often abort than go to near term; the continuance of the pregnancy to the later months (when accidental haemorrhage commonly arises) shows that the kidneys up to that time were fairly efficient.—I am, etc.,

Rugby, May 18th.

R. H. PARAMORE.

POSTERIOR GASTRO-JEJUNOSTOMY WITH
JEJUNO-JEJUNOSTOMY.

SIR,—I read with interest Mr. Gillon's note in your issue of April 24th (p. 738) again recommending posterior gastro-jejunostomy with jejuno-jejunostomy for pyloric and duodenal ulcers—because when, in 1914, he advocated it I began to perform it and continued to do so from time to time. I hoped to confirm his view that it prevented the occurrence of that dire complication the peptic or anastomotic ulcer, of which before that date I, like other surgeons, had had my share.

I find now that in a series of over 500 gastro-enterostomies I have performed this particular variety as a primary operation in 80 cases, employing clamps, not removing any mucous membrane, and using the finest chromic catgut as suture material. The results over a period of almost twelve years are as follows. Of the 80 patients, 10 cannot be traced, 4 have died, 1 has developed pulmonary tuberculosis, and 1 cancer of the stomach; altogether 16 cases which may be eliminated.

This leaves 64 available for an estimate of the value of the operation. Of the 64 cases, 47, or 73 per cent., remain so far completely cured; they eat everything, take alcohol in small or larger amounts, and most of them smoke to excess. Eight patients (12 per cent.) are much improved, but suffer some discomfort at times, 3 have marked pain and sometimes vomiting, and may be considered as probably having peptic ulcers; 6 of the 64, or 9 per cent., definitely developed peptic ulcers, for 5 of them were operated on again by myself, one for a gastro-colic fistula; the sixth suffers from the typical diarrhoea and foul eructations found in such cases, though as yet he has not been operated on again.

This operation therefore in no way protects the patient against the anastomotic ulcer. Though apparently it is more "physiological," most surgeons believe that the absence or great reduction of bile in the stomach which the entero-anastomosis produces may be a predisposing cause of the secondary anastomotic ulcer.—I am, etc.,

Huelva, Spain, May 16th.

MENTAL IRRITABILITY AND BREAKDOWN IN THE TROPICS.

SIR,—“What is the cause of the upset of mental balance which is so common in the tropics?” Such is the question propounded by your correspondent in the *BRITISH MEDICAL JOURNAL* of March 13th, 1926.

Twenty-five years' residence in a subtropical climate (20° to 23° lat.) in the upper reaches of the River Plate Valley (here called Rio Paraguay), with a summer temperature of 90° to 110° in the shade, has allowed of many observations on the causes that mostly contribute to nervous breakdown in European immigrants. The majority of the latter are more or less educated people of the middle classes and live in good circumstances. Probably no one single cause can be given as accounting for any case of mental breakdown, and it will be well to consider some of the minor things that contribute towards producing a condition of the nerves in which the European will fall a ready victim to the specially tropical causes of nervousness, neurasthenia, and insanity. The causes to be considered are:

Personal.—The habits of life of a man have a great deal to do with the stability of his nervous equilibrium, and bad habits lay the foundations for the future breakdown. The abuse of alcohol need only be mentioned, its evil effects are so very evident. The abuse of tobacco ought to be condemned; the nervous, sleepless man will get control of himself again and sleep of nights if he gives up his evening smokes. Sexual excess and masturbation are of greater frequency in hot climates than in temperate, and many a nervous wreck has been produced thus within a very short period of residence in the tropics. Want of society, or absolute loneliness, or too prolonged residence in one place, sooner or later lead to a state of mind in which the white man may go crazy unless he gets a change.

Pathological.—Slight chronic ailments that worry or depress, chronic malarial infection with neuralgia, headaches, etc., chronic intestinal infections, mucous colitis, chronic dysentery, intestinal parasites, congestive conditions of the liver—many such ailments, although not unfitting a man for duty, render him a very easy victim to the specially tropical causes of nervous excitation and irritation. Many cases of suicide can be traced to the depression produced by the knowledge of the incurability of diseases such as leprosy. The white leper, when he has tried everything within his reach in vain, puts a bullet through his head.

Social.—Ignorance of the native language, unwillingness or incapacity to acquire it, inadaptability to and want of consideration for the customs of the natives, very often produce an attitude of suspicion and unreasonable contempt towards the people, leading to a feeling of hostility and fear which sooner or later lands the European in difficulties. The Spanish-Indian-American very soon discovers the mental attitude of his white overseer towards him, and is prepared to anticipate any crazy act of overbearing authority. The native very generally gets his knife or bullet in first, as one knows from the numerous cases of murders of European officials, managers, etc. From the racial point of view it is well for the white man to try from the first to neutralize the natural antagonism between himself and the native by acquiring the language of the latter, getting to know the character of the people, making allowance for their ignorance and failings, and observing a reasonable and friendly attitude towards their customs. The worry of dealing with native employees, house servants, etc., will thus be greatly diminished and one very common cause of mental irritation be partially removed. The employer will be able to sleep without a revolver under his pillow, and go out in the dark without a thought when a native calls him in the night.

Climatic.—The depressing effect of continuous high temperature will in time weaken the mental powers and nervous system of the white man, but sun and heat in themselves alone have no special effect. Combined with any or many of the minor causes mentioned above, they speedily lead to serious manifestations of nervous breakdown. There have been cases of men suffering badly from neurasthenia, who can give no history of any other

probable cause than their having had a splitting headache after standing bareheaded in the midday sun for a few minutes, and never having felt right after. Unsuitable or excessive clothing in the great heat produces a feeling of oppression and worry and irritation that is immediately dispelled by a change into lighter clothes. The tropical moon has such a powerful effect upon all forms of life that towards and during full moon the nervously disposed person requires to take greater care of himself and keep himself under greater restraint than at other times. Epileptics, lunatics, and alcoholics all have their condition aggravated during full moon. Children with intestinal parasites, especially ascaris, suffer more from convulsions then than at other periods. Europeans are unwilling to believe what the natives tell them about the moon and many other things, but they find later that the natives are often right.

Perhaps the thing that acts most powerfully on the nervous system in these parts is the north wind. This is a very dry, hot wind blowing south-westerly from Brazil through Paraguay to the Argentine. It dries up everything it comes across. Its effects upon animals of all kinds are most extraordinary. All the domestic animals, horses, cattle, dogs, fowls, suffer in the same way as man does. Its effect in weakening the higher centres and inhibiting the control over the lower functions is most alarming. Everybody's nerves are on edge. The most trivial incident, a word in jest misunderstood may lead to murder. An older native, meeting a younger of a slightly better class saluted him with “Why, boy, you've got to look almost like a man,” got a bullet from the boy and fell dead. During a north wind the number of woundings and murders is greater than at any other time. When native dances are allowed during north wind, we lie listening for the shots, or for the footsteps of those running to fetch help for a knifing case. The commonest remark for a European during north wind, when he can speak at all without snarling, is “I'll be crazy in another day if the wind don't change.” It does not matter where one is, indoors, outdoors, in the shade, in the sun, in town or in the country, the north wind gets one everywhere. Many a good man remembers with considerable regret afterwards the mad things he has said or done during his north wind fits of passion and crazy outbursts of unreasoning anger.

It is during the blowing of the north wind that suicides and murders and all sorts of tragedies happen in these countries. It may be that in other tropical countries there are similar winds or atmospheric changes that affect the nervous system in the same way, and from which there is no escape. It is, therefore, to be recommended that the minor causes of nervous and mental breakdown, such as those mentioned under the headings of “personal,” “pathological,” and “social,” be avoided or guarded against or provided for, as they all render the white man more or less unfit to stand the strain of the specially tropical conditions that cause mental breakdown.—I am, etc.,

THE PRESERVATION OF EGGS.

SIR,—In your issue of May 8th and 15th last (p. 847) Dr. H. E. Jones claims to have found that an indifferent gas—CO₂—is an effective preservative of eggs.

More than a quarter of a century ago I accidentally learned that a remarkable number of persons in Britain—people in various grades of life and belonging to many different religious sects—have constantly practised the habit of collecting the eggs laid during the Good Friday of each year and putting them aside for use in making their puddings and other sweets at the following Christmas. The nests are carefully explored late on the previous Thursday evening, and any eggs then found are removed “lest they should go bad and thus haply infect those gathered on the Good Friday.” Moreover, each Good Friday egg must be absolutely clean; if at all dirty when taken from the nest it is carefully washed with warm water applied with a soft cloth, and then dried with another soft cloth. The eggs are then stored in any

convenient vessel and put aside; an ordinary open hand-basket and a corner of the chest of drawers in the spare bedroom are usually chosen for the purpose, and there the eggs remain until wanted for use.

I obtained a dozen eggs gathered on the previous Good Friday, another dozen of the previous Thursday, and a third gathered during the following week; this was in July, and Easter had fallen early in that year. I at once broke an egg taken from each dozen in turn. Each was quite good, and had all the visible appearances of an egg such as might have been laid the same day. The rest were then laid in three separate open cardboard boxes and placed on a table in an unoccupied bedroom, where they were exposed to the full rays of the hot afternoon sun. Thereafter I broke an egg from each dozen once in a week at first, and then once a month, until I came to the end. They were, one and all, quite good, apparently quite fresh, cooking and tasting like fresh eggs. These experiments, varied in many different ways, were continued for some years. And I have by me still a few of these eggs, now over twenty years old, the contents completely dried up, but without any sign of decomposition.

When one comes to think of it there is nothing very surprising in this. The egg laid by a healthy hen is, bacteriologically speaking, sterile, and its important contents are well protected by the vitelline membrane; but if the shell be at all dirty—that is, fouled by the faecal discharges of the parent bird—then dust and the ordinary moisture of the atmosphere soon ensure a penetration of shell and membrane by saprophytic organisms, and the germs of liquecent-putrefaction speedily follow in their wake.

As I have been warned, the fluid contents of the shell begin to dry up after about the ninth or tenth month, and the drying thence proceeds at an accelerating rate. If the egg has been fertilized it does not respond to incubation after the lapse of three and a half to four months, as is usual; otherwise there is no difference between the fertile and infertile egg.

The alleged immunity of the "Good Friday eggs" is the outstanding feature of a very ancient legend, which appears to be most common among the Celtic peoples, and the pith of it lies in the belief that the thrice-repeated crowing of the cock which aroused St. Peter's remorseful conscience was rewarded by the assurance that each egg laid by its descendants on every ensuing anniversary of the first Good Friday should remain sweet and wholesome for the following twelve months. But there was one condition—the egg must be clean.—I am, etc.,

Hertford, May 25th.

C. E. SHELLY.

PITUITARY GLAND BY THE ALIMENTARY CANAL.

Sir,—The discussion in your columns on the action of pituitary gland on uterine contraction when given by the alimentary canal reminds me of my own experience with it.

In *New Serum Therapy* (Baillière, Tindall and Cox, 1905) I reported the definite action of antidiphtheria and anti-streptococcus serum orally administered on uterine contraction in labour, and cases were given. Two drachms of a low potency antidiphtheria serum orally in an exhausted uterus changed the whole aspect of the case in from ten to fifteen minutes or less by its restorative action on the uterine muscle, and ensured a normal and vigorous labour. That this was due to the pituitary content of these serums was confirmed by the occasional unaccountable failure of the serum to act, just as the pituitary fails at the present day.

The pituitary secretion is part of the non-specific resistance of the animal, and is developed in immunization to diphtheria and streptococcal infection to protect and restore the tissues affected, which are toxophile to these antigens.—I am, etc.,

Melbourne, March 31st.

D. MONTGOMERIE PATON.

GANGRENE IN THE NEWBORN.

Sir,—Dr. W. R. Grove will perhaps be interested to hear of a somewhat similar case to his own which is recorded on page 398 of Dr. John D. Rolleston's translation of August Ritter von Reuss's monumental work on *Diseases of the Newborn*. To quote verbatim:

"Foltanek has described a case of gangrene of the right foot which was observed on the eighteenth day, and which was obviously the result of an embolic process of unexplained origin. The case terminated in recovery after spontaneous amputation."

There is an excellent coloured drawing of the condition on the opposite page. The line of demarcation is seen just above the level of the ankle.

One other case mentioned by von Reuss is less fully described.

"Haas has seen gangrene of the toes develop in four weeks in an infant who had cyanotic discolouration of one of the lower extremities at birth."

Spontaneous gangrene is apparently an infinitely rare disease in the newborn infant, as Dr. Grove points out, and his almost complete immunity to embolism is all the more striking in view of the "comparatively" frequent occurrence of umbilical sepsis with involvement of either arteries or vein in the septic process.—I am, etc.,

Glasgow, April 27th.

J. INGLIS CAMERON.

THE COLLEGE OF NURSING.

Sir,—We venture to appeal to our colleagues in the medical profession for an object which we are confident will enlist their sympathetic consideration—namely, the endowment of the College of Nursing.

The College of Nursing was founded in 1916—to provide a central organization for the nursing profession; to raise the standard of training and examination of nurses; to promote the higher education of nurses; to attract to the nursing profession the best type of women. The qualification for membership is a three years' training.

The College, which now has over 25,000 nurses on its register, is recognized by the Ministry of Health as a training centre for the Health Visitors' Certificate. There are forty-one branches of the College, and seven residential and other clubs; there are also two convalescent homes. Scholarships to the number of forty-five have been awarded to members for post-graduate work. There is a loan fund, and a special scheme for insurance against sickness and accident. Free legal advice is available to members. There is a library open to all students of nursing, and books can be borrowed.

The Public Health and Sister Tutor sections were formed for those members who are engaged in these special branches of work.

The College is a most democratic body, the nurses on the register electing by postal ballot whomsoever they please to represent them on the Council, whether nurses, doctors, or laymen. One-third of the Council retires every year.

The headquarters of the College are situated in Henrietta Street, London, W.1.

To meet the cost of management of the College of Nursing an endowment fund of £100,000 is required. £67,000 has already been raised, and of this sum the members of the College themselves, with the help of their friends, have subscribed or collected over £35,000, to achieve which they have worked extremely hard.

Medical men and women are beholden to the nursing profession for much assistance. First as students in the wards, then many of them as house officers; all of them in their practices, and all of them when seriously ill. There are vast numbers of medical practitioners who are only too willing, and are always ready, to testify to the outstanding services the nursing profession has rendered them in their life's work. The work of a nurse is of an exacting nature, and it still does not command a remuneration comparable to that which obtains in many similar walks of life. Nurses in general have no pension fund to fall back upon, except such as they themselves may be able to subscribe to. The working life of a nurse is short, and nurses over a certain age find it difficult to secure engagements.

These are some of the dominant reasons why we think medical practitioners will be glad to contribute a sum, however small, to help the nurses to endow their College. Such donations would be a signal indication of the appreciation of the medical profession for the great and indispensable help it has received in the past, and will continue to receive in the future, from the members of the nursing profession. (The amount subscribed by members of the medical profession since the appeal was first issued is £878.)

Donations of any amount will be thankfully received;

they may be sent to the honorary treasurer, or any of the undersigned, addressed to the College of Nursing, Henrietta Street, W.1, from which an official receipt will be furnished.—We are, etc.,

(Signed) COMYNS BERKELEY, *Hon. Treasurer*;
E. C. PERRY, *Hon. Secretary*;

D. J. MACKINTOSH,
Medical Members of the Council elected
by the Members of the College.

NATIONAL HEALTH INSURANCE AND THE EMPLOYMENT OF TUBERCULOUS PATIENTS.

Sir,—One of the greatest obstacles to the employment of tuberculous patients—both ex-sanatorium and others—is sickness benefit as administered at present under the Insurance Act.

Every tuberculosis officer must have on his books patients who are unfit for varying periods for whole-time employment, but who could work shorter hours or at lighter occupations with benefit in every way. It is, however, very difficult to persuade a man that it is to his advantage to earn 15s. a week doing light work about a farm or, say, 20s. as a part-time jobbing gardener, when he can get from 7s. 6d. to 10s. a week for doing nothing. The same is true of women who could often find work mending, knitting, and so on, before proceeding to something more strenuous and remunerative as their condition improves.

So far as many of the tuberculous are concerned, sickness benefit reproduces all the evils of the dole. Pulmonary and non-pulmonary cases are both affected. Instead of convalescence being a period of steady improvement, it permits the patient to degenerate into a state of chronic invalidism, until ultimately his only job is getting the weekly "line" from the panel doctor.

Of course, there are patients who rise superior to circumstances and return or attempt to return to their former work, but there is a residue of unemployables who need not have reached this unenviable position.

In this county of Roxburgh help has been forthcoming from two sources: first, the Post Office by employing tuberculous pensioners as part-time rural postmen has given several men suitable occupation, to their very great benefit; secondly, the mills will frequently take back patients for shorter hours if proper representations be made.

So far as the genuine invalid is concerned, I would like to see sickness benefit increased and extended, but it is evident that sickness benefit as drawn by many convalescents requires reconsideration. Some sort of sliding scale is required. The patient who can do some work and will not, should not be able to draw full benefit; whereas those who can and will earn a little should not be penalized by losing the whole allowance.—I am, etc.,

Newtown St. Boswells, Roxburgh, May 17th.

G. B. PAGE.

NAPOLEON'S PRIZE FOR RESEARCH ON CROUP.

Sir,—Dr. Parry (whose letter appears in your issue for May 8th and 15th at p. 847) cannot have sought very far. The history of the competition for this prize is perfectly well known. There were seventy-nine competitors, and the prize was divided between Jurine of Geneva and Olbers of Bremen, and more than one writer has given an account of the circumstances which led to Napoleon's action. The English reader will find an excellent summary of the affair in the book entitled *Diphtheria*, issued by the Medical Research Council in 1923.—I am, etc.,

May 18th.

E. W. G.

Sir,—The prize proposed by Napoleon for the best memoir on the croup was awarded in 1811, the successful competitor being Heinrich Wilhelm Olbers (1758-1840), a physician of Bremen. Olbers is better known as an astronomer, having discovered the minor planets Pallas (1802) and Vesta (1807); and in 1781 he had the honour of first rediscovering the planet Uranus. He also discovered five comets and made important researches on the probable lunar origin of meteoric stones.—I am, etc.,

Kiasa, co. Kildare, May 19th.

LEO H. FISHER, M.B., B.Ch.

Obituary.

SIR JOHN WILLIAMS, BT., G.C.V.O., M.D., F.R.C.P.,
Emeritus Professor of Midwifery, University College, London,
and Consulting Obstetric Physician, University College
Hospital, London.

We regret to have to record the death on May 24th, at his house at Aberystwyth, of Sir John Williams, Bt., Emeritus Professor of Midwifery in University College, London.

John Williams, born on November 6th, 1840, at Blaenllynant, Carmarthenshire, was the third son of the Rev. David Williams, a Congregational minister who was also actively engaged in farming. The family always spoke Welsh when together, and until he went to school Williams rarely conversed in English. He received his general education at the Normal College, Swansea, and after a short time with a medical practitioner in Swansea entered University College, London, in 1861. He became obstetric assistant in 1864, and in the following year, after taking the diploma of L.S.A., house-physician. He took the diploma of M.R.C.S. in 1866, graduated M.B.Lond. a year later, and became M.D. in 1867. He was admitted M.R.C.P.Lond. in 1873, and was elected a Fellow in 1879.

When he had ended his term of office as house-physician in 1865 Williams returned to Swansea, where he engaged in general practice for a few years. In 1871 he was offered, and with some hesitation accepted, the appointment of assistant obstetric physician to University College Hospital; in 1883 he became obstetric physician jointly with Dr. Graily Hewitt, and, on that physician's retirement in 1887, professor of obstetric medicine in the College. He held the chair until 1893. He was honorary LL.D. of Edinburgh, Glasgow, and Aberdeen, and D.Sc. Wales, and was honorary fellow of numerous British and foreign societies. He received a baronetcy in 1894 and was made K.C.V.O. in 1902 and G.C.V.O. in 1911 when the foundation stone of the Welsh National Library was laid. He was Grand Cross of the Dannebrog Order of Denmark. Many distinctions were conferred on him by his grateful fellow countrymen, including the D.Sc. of the University of Wales and the presidency of the University College of Wales. Sir John Williams married Mary, the only daughter of Richard Hughes of Ynystawe; she died in 1915 without issue.

His Contributions to Gynaecology.

After settling in London he did not at first make very rapid progress in private practice. The specialty to which he devoted himself was in a state of transition. There were those, especially among the older practitioners, who deprecated operation and made great use of pessaries; and there were those who were ready—as some of their critics said even over-ready—to operate. Williams took a middle position; he did not hesitate to operate when he considered it justifiable, but he did not consider it justifiable for as many conditions and in as many cases as some others. His tendency towards conservatism was all the more influential because he was himself a skilful abdominal operator. In all the controversies of the time—and they were often embittered—he was a powerful ally of Dr. Matthews Duncan. It was perhaps partly through the influence of Duncan and of Sir William Jenner that Williams eventually obtained conspicuous success in private practice. He was appointed physician to Princess Beatrice of Battenberg and physician accoucheur to Queen Mary, and was in attendance at the birth of the Prince of Wales.

Sir John Williams was not a voluminous writer; his most important separate contribution to medical literature was his work on cancer of the uterus. For many years he took an active part in the work of the Obstetrical Society, which he joined in 1872; he passed through all the usual offices till he became president in 1887. It was to the *Transactions* of that society that his most important contributions were made. The first was entitled "The mechanical action of pessaries." These appliances were in great favour at that time (1876), but, as the discussion disclosed, the authorities of the day were at variance as to the simplest questions concerning the supports of the pelvic viscera and the mechanism of any artificial support.

In short, the pessary was then really an empirical agent in uterine therapeutics. In 1877 he read to the same society an important paper on "The pathology and treatment of membranous dysmenorrhoea." His conclusion was that the dysmenorrhoeal membrane was simply the decidua shed entire, instead of coming away in fragments as usual. In some cases it was cast without pain. It did not represent any essentially inflammatory condition, either of the ovaries or even of the uterus; metritis might be a result, or an accidental predecessor or concomitant, of membranous dysmenorrhoea, but was not its cause. The shedding of the entire decidua was, Williams maintained, the result of hyperplasia of connective tissue through imperfect evolution of the uterus at puberty or faulty involution after gestation. Though he admitted that the hyperplasia might be the product of acute inflammation, he was particularly reluctant to admit of any causal relation of inflammation to dysmenorrhoea. Very different opinions prevailed at the date when the paper was read; indeed, a distinguished authority declared, in discussing it, that stenosis of the os uteri was, at least in some cases, a cause of dysmenorrhoea, and that therefore the os externum should be divided with scissors and a galvanic stem applied, in order to "alter the nutrition of the uterus." The physiology of this "altering of nutrition" was never satisfactorily explained by its advocates, and Williams held that stenosis was charged with many things of which it was not guilty and often diagnosed where it did not exist. One of Williams's best services to gynaecology, well illustrated in this early communication, was his objection to take anything for granted or to defend a method by argument, rather than to determine what methods were needed to cure any morbid condition.

The nature of painful menstruation in all its varied forms was reviewed five years later in one of Sir John Williams's most elaborate works, his monograph "On the natural history of dysmenorrhoea," read at a meeting of the Obstetrical Society in the spring of 1882. Most of his views on the subject have been accepted, and those who opposed them were no doubt prejudiced through their belief in fallacious theories that favoured certain lines of treatment now quite abandoned. The vigorous debate which followed the reading of Williams's paper will throw much light on the views held by leading gynaecologists in the eighties; and it is recorded in full in the twenty-fourth volume of the *Transactions of the Obstetrical Society*. As far as oratory and preciseness of definition of opinions for and against the monograph are concerned, the discussion in question, in which men of much reputation, such as Barnes, Graily Hewitt, Gervis, and Galabin took a part, was of considerable merit, and gynaecologists of to-day might profit by reading through these all but forgotten debates.

Another contribution Williams made to the Obstetrical Society's *Transactions* (vol. xxvii, 1885, p. 112), "On the circulation in the uterus, with some of its anatomical and pathological bearings," proved of high practical value. He demonstrated, what was not at the time clearly understood, how the uterine arteries as they run up the sides of the uterus give out offshoots which encircle the body of the organ. From these arterial circles numerous branches run towards the mucous surface in a direction perpendicular to that surface, anastomosing freely and terminating under the mucous surface in conspicuous capillary loops. From these anatomical facts Williams drew several conclusions in regard to the disturbance of circulation caused by flexions and prolapses. It was still customary in 1885 for gynaecologists of the old and new schools to dispute about flexions. Williams, on the strength of experiments on the cadaver, as well as of clinical observations, insisted that a flexion, however acute, does not interfere with the flow of blood from the uterus. This important monograph included much that was original.

In the summer of 1885 Williams read instructive notes "On serous perimetritis," based upon three cases which he minutely analysed. The paper and the active discussion it excited were chiefly valuable for the light they threw on the symptoms and physical signs observed when serum is effused in association with pelvic peritonitis: none of the experts, not even Williams himself, was bold enough to state how far

serous perimetritis could be ranked as a definite if not a primary condition.

Sir John Williams distinguished himself greatly during the two years 1887-8 by his skilful conduct of discussions when he held the office of President of the Obstetrical Society. That he foresaw how ephemeral would be the fame of Apostoli's method, then attracting great interest, any worker interested in electrical therapeutics can learn on referring to Williams's scathing remarks when he presided during the discussion on several papers on electrolysis in gynaecological practice, in the summer of 1888.

In the autumn of 1886 Williams delivered the Harveian lectures before the society which bears that name. Two years later they were reproduced in book form as a treatise entitled *On Cancer of the Uterus*, a work adorned with fine illustrations by Professor Herbert Spencer, Mr. Frank Collins, and Mr. Burgess, and drawings of microscopic sections by Dr. Boxall. Williams discussed his subject thoroughly, according to the views of that period, but his verdict on operations, now that more radical measures have become general, has undergone modification. He asked, how much of the uterus could be removed by the minor or less severe operation? Could enough be amputated to ensure prevention of recurrence? Experience has sanctioned his reply to that question. He believed that it was possible to extirpate cancer from the uterus by supravaginal amputation; he maintained that in so far as the prevention of recurrence in the uterus itself was concerned, total extirpation of the organ presented no advantages over partial amputation. Williams, however, was judging Freund's and Czerny's total hysterectomies; Wertheim's more radical operation was not introduced until many years later.

As a public speaker he was not brilliant; but his remarks were always apposite, sensible, and courageous. At the bedside he spoke sometimes in a voice so low as to be inaudible by all the students standing around. But for his assistant and clinical clerks it was a valuable education to follow him and ascertain the correctness of the notes of the physical signs of the "present state" which he dictated in every case.

The National Library of Wales.

While still in the full tide of successful practice in London he retired to a country house he had acquired at Llanstephan in Carmarthenshire, under the shadow of the ruins of the castle of that name, near the mouth of the river Towy. When the National Library of Wales was established at Aberystwyth he went to reside there. Quite early in his career he had conceived the idea of collecting Welsh books, which he from the first hoped might eventually prove the nucleus of a national library. The hobby thus begun remained with him ever afterwards. It was his recreation and solace throughout his professional career in London, bringing him into relation with his fellow countrymen then on the council of the Cymmrodorion Society, and eventually on the council of the University College of Wales, Aberystwyth, of which he became vice-president in succession to one of the founders of the College, Alderman J. F. Roberts, the brother of that distinguished Welsh physician Sir William Roberts of Manchester.

The governors of the College had commenced to form a collection of Welsh books and manuscripts as early as 1873, and in that year, on the initiative of Sir Hugh Owen, it was decided at the National Eisteddfod in Mold to establish a Welsh National Library. From that time forward the library steadily grew, receiving gifts from all parts of Wales. For over thirty years Sir John Williams continued to purchase books, manuscripts, prints, and drawings destined to find a place in the Welsh National Collection. These included the priceless treasures of the Peniarth and Shirburn collections. The former is described in the report of the Historical Manuscripts Commission as consisting

"of 519 MSS. works in Welsh, Cornish, English, and Latin, four-fifths of them having originally formed the Hengwrt Collection brought together by the antiquary Robert Vaughan (1592-1667), afterwards passing by request to W. E. Wynne of Peniarth, Merioneth, and removed there in 1859. The present collection of

Peniarth is undoubtedly the premier collection of Welsh MSS. both in extent and in quality. Here we have the oldest MSS. of the Laws of Wales in Latin and Welsh, the oldest version of the Mabinogion and of the Arthurian and other Romances; the oldest and the only perfect copy of the Holy Grail; an early translation of a portion of the Gospel of St. Matthew; an immense body of poetry ranging from the Black Book of Carmarthen (the oldest of the Four Ancient Books of Wales, of which two others are in the possession of the National Library) down to the 18th century historical works current in the Middle Ages. We have here also not only the most extensive collection of pedigrees, but by far the oldest MSS., with authentic contemporary accounts and references to sources of information."

The Shirburn Collection was formed by the Rev. Samuel Williams and his son, the Rev. Moses Williams, F.R.S., between 1560 and 1740. A competent authority wrote of it:

"It consists of 154 MSS. in Welsh and Cornish, and a large number of books printed in Welsh before 1740. It is this collection of early printed books in the Welsh language which has made the Shirburn Library famous. Of 21 books known to have been printed in Welsh before 1600 it contains 15. (Four of the others either have been, or will be, placed in the National Library)."

With the addition of the Cwrtmawr, the Newtown, and the University College of Wales collections of MSS., either already included in or destined for it, the Welsh National Library at Aberystwyth had already become the foremost library of Celtic literature in the world.

The decision (1905) of the Special Committee of the Privy Council that the National Library of Wales should be established at Aberystwyth received the cordial assent of the people of Wales, who quickly contributed towards the cost of the buildings an amount sufficient, with the equivalent grant of the Government, to defray the entire cost of the buildings; all sections and classes in Wales contributed, including the quarrymen of North Wales and scores of workmen's clubs and institutes in South Wales. Gifts of books and MSS. have continued to come in from all parts of the country, and the library has, under the Copyright Act, received the same privileges with regard to books printed in the United Kingdom as are already enjoyed by the Bodleian Library, Oxford, the University Library, Cambridge, the Advocates' Library, Edinburgh (now the Scottish National Library), and the Library of Trinity College, Dublin. On January 1st, 1909, the Llanstephan Collection of books and MSS. was transferred to Aberystwyth, the University College collections about the same time, and the Peniarth MSS. almost immediately after.

The new buildings, designed by Mr. S. K. Greenslade, erected on the commanding site given by Lord Rendel on the Grogthyan Hill, overlooking Aberystwyth bay, are worthy of the great library which is housed within them, and are a fitting symbol of the links which bind the people of Wales at home and abroad in a common allegiance to their native language, literature, and institutions. The Treasury made a grant of £4,000 per annum towards the maintenance of the library, to which a Royal Charter was granted in March, 1907, by H.M. King Edward VII. The object of the library as defined by its charter is—

"the collection, preservation, and maintenance of manuscripts, printed books, and other works . . . which may help to attain the purposes for which the University of Wales and its three Constituent Colleges were created and founded, especially the furtherance of higher education and of literary and scientific research."

Equally important is the function of the library in the circulation of duplicate copies of books for the use of lectures and tutorial classes held throughout the Principality. In the past literary composition in Wales has been the concern and recreation of the peasant and working man to a degree probably not reached in any other country. The National Library guarantees the perpetuation of this national characteristic. It fell to the lot of Sir John Williams to see the dream which he conceived in youth realized in a form surpassing his highest expectation. On July 15th, 1911, the foundation stones of the library were laid by King Edward VII and Queen Alexandra. It is generally recognized in Wales that the single-minded devotion Sir John showed to this great national object, the sacrifices he made for it, and his unflagging zeal and courage in its advocacy commended the National Library in a peculiar degree to the affection of the people of Wales. The beautiful reproduction of the Black

Book of Carmarthen edited by Dr. Gwengvryn Evans in 1906 is dedicated to Sir John Williams as "The first President of the Welsh National Library, the first in personal effort for its establishment, the first in personal sacrifice for its good, and the first in the importance of his contributions to its treasures."

By his character, even more than by his scientific work, he exercised a powerful influence upon obstetrics and gynaecology. With a less forceful personality than Matthews Duncan he was not less tenacious of right, and being himself a skilful operator he was able to judge better than a non-operating gynaecologist of the true value of operations.

Sir John Williams excelled as a host, was a good judge of wine and cigars, and gave delightful dinners at his house and at the Devonshire Club, which many will recall with pleasant memories. He was fond of fishing, and occasionally shot. He had the three qualities—honesty, kindness, and decision—which his master Jenner once said were the sole requisites for successful practice; but to these he added a thorough knowledge of his professional work, which Jenner humorously said was of no consequence, though he was an outstanding example to the contrary.

Dr. HERBERT SPENCER, his successor in the chair of obstetric medicine, has been good enough to send us the following tribute:

The death of Sir John Williams, advanced in years though he was, came as a great shock to his old pupils and friends. Those of us whose memory goes back to the days when he was a great teacher and a great practitioner in London will especially grieve at the loss of their old teacher, "Dr. John," and are in a better position than the younger generation of obstetricians to appreciate the value of the service he rendered to his specialty. He and Dr. Matthews Duncan were the great teachers in the seventies and eighties; but though Duncan was intellectually his superior, John Williams had the great advantage of being an operator, and it is not too much to say that it was his success as an ovariectomist at University College Hospital which was the chief factor in obtaining for obstetricians the right to operate at the hospitals of other medical schools, a right now universally recognized, to the great advantage of gynaecology. His teaching was widely extended owing to the fact that many of his assistants became obstetricians and gynaecologists in the hospitals of the London and provincial schools.

The chief records of his scientific work are to be found in the *Transactions* of the Obstetrical Society of London and in his Harveian Lectures on cancer of the uterus: all are characterized by accuracy and honesty of statement and soundness of judgement.

As a clinical teacher he set a good example of careful note-taking; as an operator he was quick, careful, and skilful—"un opérateur sûr de sa main," I heard a distinguished foreigner describe him.

But, important as were his contributions to obstetrics and gynaecology, it is not to these that his pupils revert on the sad occasion of his death. They think rather of his kind and lovable personality, his humanity, his geniality, and his hospitality, which we all used to enjoy so much. He was a great obstetrician and a great teacher; but above all a good and kind man and a delightful companion. True and true was his friend Champneys's dedication to him: "*Johanni Williams medico insigni, sodali dilectissimo.*"

Sir John Williams will be mourned by many; but by none more than by those who knew him best as pupils, colleagues, and friends. To them the words of Horace apply:

Multis ille bonis flebilis occidit
Nulli flebilior quam tibi.

ELDON HARVEY, O.B.E., V.D., M.R.C.S.Eng.,
L.R.C.P. Edin.

By the death of Dr. Eldon Harvey, on May 4th last, the colony of Bermuda loses, not only one of its best known medical men, but also a man who, throughout a long life, had devoted himself to public affairs and the welfare of his native islands.

He studied medicine at St. Thomas's Hospital, and took

the diplomas of M.R.C.S.Eng. and L.R.C.P.Ed. in 1881. He then spent two years as a ship surgeon with the White Star Steamship Company in the China, Japan, and San Francisco Division, and afterwards returned to Bermuda, where he went into private practice. In 1891 he was appointed medical superintendent of the lunatic asylum, and was medical officer of health from 1894 to 1920; afterwards he continued as a quarantine and health officer. He was surgeon to the Bermuda Volunteer Rifle Corps from 1895 to 1919, when he retired with the rank of surgeon major, having received the Volunteer Decoration some years previously. He was secretary to the local Branch of the British Medical Association for many years, and was a delegate to the Annual Meetings of the British Medical Association at Bristol in 1894 and at Oxford in 1904, and to the British Congress on Tuberculosis in London in 1891. He had much to do with the founding and administration of the cottage hospital, of which he was surgeon in charge in 1895, and later used all his influence to get a general hospital built, with the result that the King Edward VII Memorial Hospital was opened in 1920; this institution will shortly have seventy beds, and has a training school for nurses which is of great value to Bermuda. In addition to his professional work, he found time to be a common councillor of the city of Hamilton for twelve years, and was a representative in the local House of Assembly from 1904 onwards, with one short break of a few months. He will be remembered with affectionate esteem, especially by many of his colleagues all over the world, as he had much to do with the Royal Navy and mercantile marine as quarantine officer, in which capacity he held the record of having kept only one ship waiting in over thirty years, and then only because no boat could attempt to put him on board.

Dr. HENRY DUTCH, who died on April 30th, aged 64, at his residence in London, was born in Dublin, and received his medical education at St. Mary's and the Middlesex Hospitals and Trinity College, Dublin. He obtained the diploma of L.R.C.P.Lond. in 1886, the M.D.Brux. degree in 1896, and the M.R.C.S.Eng. in 1897. He was clinical assistant to the Westminster Ophthalmic Hospital, examiner to the St. John Ambulance Association and the London County Council, resident midwifery assistant to the Coombe Hospital, Dublin, and house-surgeon to Guinness's Dispensary, Dublin. He was surgeon major to the 4th City of London Regiment, Territorial Force, and physician to Bawcroft Military Hospital in 1918; he served also on the medical board of the Duke of York's School. Dr. Dutch was a member of the Westminster City Council, and represented the Grosvenor Ward for twenty-five years. He was the inventor of a diagnostic appliance to which he gave the name of "auroroscope." He leaves a widow, and one daughter who is also a councillor of Westminster.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

Registration of Nursing Homes.

THE Select Committee of the House of Commons on the registration of nursing homes resumed the taking of evidence on May 19th, Sir Cyril Cobb presiding. The witness was Dr. F. N. K. Menzies, medical officer of the London County Council, who gave evidence on the working of the system of compulsory registration and inspection of lying-in homes for which the L.C.C. had obtained parliamentary powers in 1916. He referred to cases of homes with no proper equipment and with unsatisfactory sanitary accommodation. In this class of place the nurses were untrained. There was some overcrowding. Sir Cyril Cobb asked why in the L.C.C. scheme of 1916 nursing homes under medical control were exempted from inspection. The witness said strong pressure was brought to bear on the Council and on Parliament by the medical profession. At present there were only nine such exempted lying-in or mixed homes in London out of 277, and their character was such that exemption was eminently reasonable. Each was vouched for by two independent medical men. His opinion was that if the present Committee recommended the inspection of nursing homes the same exemptions should apply. In 1920 the Council had obtained further powers in regard to the refusal of certificates and the issue of by-laws. It had found the latter power very useful. Since 1915 312 licences had been cancelled voluntarily. There was no general complaint that registration and the by-laws had increased costs. Ninety-nine homes were "mixed," for lying-in and general cases; he saw no objection to this. The inspection of maternity homes was done by four women inspectors who were responsible in London for the administration

of the Midwives Act. A sanitary inspector visited the homes to examine on lighting, space, sanitation, and proximity of nuisances. For mother and child they expected a cubic space of 960 feet; for the mother herself 800 feet after confinement and for women before confinement 600 cubic feet. The L.C.C. worked in complete co-operation with the borough councils, but up to the present had not delegated powers to the boroughs. In London the borough councils were the maternity and child welfare authorities, but the L.C.C. was the authority for the Midwives Act and for the Children's Act, 1918 (Part I). It had tried in Greenwich the experiment of consolidating all these powers into the hands of the borough councils, but had discovered that (ill Parliament authorized the delegation of powers under the Children's Act and under the Midwives Act the experiment was impracticable. Witness explained that there was at least an annual inspection of lying-in homes and that medical officers undertaking duties under the Midwives Act were instructed to inspect whenever their duties took them into the neighbourhood of a lying-in home. Answering the chairman, witness said he was in favour of the registration of nursing homes as apart from lying-in homes. He was not entitled officially to give evidence proving the need for this. He did not know whether the Council had received any representations in favour of the registration of nursing homes. Generally speaking, people who had lying-in homes were in favour of registration. Those persons conducting homes which they knew could not be approved had moved out of London into other areas.

Dr. Shiels asked whether, if doctors' nursing homes were, as witness said, all satisfactory, witness would explain why they should be exempted. Would the witness be surprised to learn that the Committee had evidence of doctors' homes which were not so satisfactory? Witness could not give an opinion. They had not made an absolute rule that there must be a certified midwife or a trained nurse in charge of all cases. He was satisfied with the competence of their women medical inspectors to judge the quality of nursing. He would have the strongest objection if the proposed bill for registration of nursing homes interfered with the powers which the L.C.C. had now got, which were working very well. Parliament would be well advised to trust more to the local authorities instead of always looking to the Minister of Health for action. The provision for lying-in at suitable institutions or registered homes in London was equal to 60 per cent. of the confinements—a very high figure.

Sir Richard Luce asked why, when there was a greatly increased tendency for women to be confined away from their own homes, there was little increase in the number of homes registered in London for lying-in. The witness replied that at least nine local authorities in London had established municipal maternity hospitals. Witness also remarked that nearly all local authorities throughout the country were appointing as assistant medical officers women who were thoroughly qualified to inspect maternity or surgical homes. The inspector should always be medically qualified, though a nursing inspector might supplement the work. Answering Dr. Davies, witness said he thought there were fewer inefficient authorities among county councils than among other public bodies. He thought that there should be registration even when a medical practitioner took in one elderly patient, if that was for reward. A visit once a year would probably suffice for such a case. Inspectors must be trusted to use their powers with discretion. The L.C.C. inspectors had not found a lower standard in homes run by non-certified midwives than in homes run by certified midwives. He was certain that if the L.C.C. had carried out their inspection by trained nurses they would have had great friction. There had been only nine cancellations of licences since registration of lying-in homes came into force in London. Trafficking in infants was the reason in several cases. Others were for structural defect, serious neglect of infants, and bad character of the keeper of the home. Two were purely formal cancellations.

Dr. Menzies said that nursing homes which were attached to hospitals or had been specially designed, built, and equipped as private hospitals, and those which had been adapted from ordinary dwelling-houses, were used almost entirely for the care of acute cases or patients only requiring short periods of residence. They were generally expensive and only resorted to by persons of the middle and upper classes. They were patronized by leading members of the medical profession. Those adapted from ordinary dwelling-houses were owned and maintained very commonly by hospital sisters who had been encouraged to venture into the private nursing home business by the promise of professional support from the physicians and surgeons of the hospital to which they were attached. These homes often had many deficiencies, especially having regard to the high weekly fees demanded. They usually lacked an operating theatre, even of the most modest kind, operations being carried on in the patient's bedroom, which might not be suitable. Staircases might be narrow, crooked, and awkward, but the structure of the house made the provision of a lift impossible. The provision of a laboratory, x-ray room, and equipment for special purposes, such as electrotherapy, was almost unknown. Although the nursing staff was usually good, the domestic staff was often a greater difficulty than in private houses. Despite all these defects, such homes could not be said to be insanitary, nor were the patients inefficiently cared for medically or surgically. The patient simply paid a very big price for a comparatively poor service, which contrasted unfavourably either with the advantages offered the poorest class by voluntary hospitals and Poor Law infirmaries, or to the richest class by the highly expensive clinics such as those at Ruthin and Windsor. The patients who normally went into the nursing homes which he had described in London had at present no choice in the matter and were sent by eminent members of the medical profession. He doubted whether any by-laws which could reasonably be enforced by a local health authority would materially reduce the cost or improve the conditions of the ordinary private nursing home, but he did not think

that there would be any opposition to registration if the Select Committee decided to recommend it. The most difficult group from the medical point of view were the homes which catered for persons suffering from chronic diseases such as paralysis, nervous disorders not certifiable, chronic heart disease, chronic bronchitis, when these patients were regarded as above the Poor Law standard. The great bulk of such patients could only pay from 25s. to 50s. a week for their care, board, and lodging. They were not looked after by a trained nursing staff, and were not regularly visited by doctors. The accommodation was that of a poor-class dwelling-house with the ordinary appointments. Such homes compared unfavourably with the well known voluntary institutions providing accommodation for this type of patient, or indeed with well managed Poor Law infirmaries. It did not appear possible to Dr. Menzies to do much to improve the conditions in this type of home cost to the patient, but registration would tend to raise the standard of these homes, instances there was only one patient, or cared for by the "keeper" of the home.

Dr. Menzies said he had seen something of the problem of nursing homes all over England and Wales, as well as London. He believed that the most hopeful solution of it was by a considerable extension of the system of providing pay wards and pay beds in voluntary hospitals and Poor Law infirmaries, by provision of hospital annexes for private paying patients to voluntary hospitals, and by the provision of specially built and designed private hospitals or nursing homes. He knew examples of these last, some provided by business men on commercial principles and some by philanthropists. The management committees of voluntary hospitals were waking up to the need of making provision for paying patients, and in a few years there would be a considerable increase in the number of beds available in voluntary hospitals for this purpose. The patients made their own arrangement with the physician or surgeon in attendance with regard to his fee, these arrangements being in some cases subject to the approval of the hospital board of management. The only solution Dr. Menzies could see of the financial difficulties in dealing with the class of chronic patients to whom he had referred was the provision of suitable accommodation in institutions owned and maintained by public authorities. The patient might contribute so much of the cost of maintenance as his or her financial condition permitted. The problem would assume a different aspect from the point of view of the patient and friends when Poor Law infirmaries became municipal hospitals. In the meantime, registration should be proceeded with on the lines found satisfactory for nursing homes, and in the administrative County of London it should be carried out by the London County Council. He was surprised that business men had not seen that there was a great field for the provision of good nursing homes, especially if they "roped" the medical profession into it. The kind of thing which was going to help the public was for the voluntary hospitals to extend, as they were doing all over the country, paid hospitals and paid beds. Every London general hospital was realizing that it had to provide these beds, which paid for themselves. Anyone who had the chance would rather pay three or five guineas for such accommodation than fifteen guineas for a nursing home. He did not think that registration would shut up any existing nursing homes. When an alternative was available they would not need to worry about registration.

The Committee adjourned till June 8th.

Sanitation of Offices.—Answering Lord Henry Cavendish Bentinck, on May 20th, Mr. Chamberlain said the attention of local authorities was drawn in a Home Office Circular of 1912 to the judgement in the case of *Baker v. Willoughby* as to their power to inspect workplaces in a sanitary condition. This judgement did not, and it might be well to have a test case to make the position clear. At a meeting of the Unionist Health and Housing Committee earlier in the week, Dr. Fremantle presiding, a discussion arose on the inspection of offices, concerning which the Labour party had presented a bill. It was pointed out to the Committee that the death rate for clerks was not much over the average for the population, but an indication was given that in the opinion of the Ministry of Health local authorities could inspect offices as "workplaces," and lay down conditions concerning them. The Committee learned that if this interpretation of the law were not upheld by the courts the Ministry of Health would be prepared to propose further powers for inspection of offices.

The Services.

THE KING has approved of the appointment of Lieut.-Colonel E. Ryan, C.M.G., D.S.O., R.A.M.C., to be Honorary Physician to His Majesty, and to be promoted to the brevet rank of colonel, with effect from February 18th, 1926, in succession to Lieut.-Colonel and Brevet Colonel Sir Edward S. Worthington, Kt., K.C.V.O., C.B., C.M.G., C.I.E., R.A.M.C., who has retired.

DEATHS IN THE SERVICES.

Brigade Surgeon Thomas Bennett, one of the oldest officers on the retired list of the R.A.M.C., died at Seatown, New Zealand, on March 28th, aged 90. He was born at Templemore, Tipperary, on November 10th, 1835, and educated in Dublin, where he took the L.R.C.S.I. in 1857. Entering the army as assistant surgeon on January 22nd, 1858, sixty-eight years ago, he became surgeon-major on April 1st, 1873, and retired, with an honorary step as brigade surgeon, on April 17th, 1883. A few months later he

commuted his retired pay. As a regimental medical officer he served in the 14th Foot, now the Prince of Wales Own West Yorkshire Regiment.

Lieut.-Colonel Edward Hearne Joynt, R.A.M.C.(ret.), died at Blackheath on April 27th, aged 79. He was born on January 19th, 1847, graduated as M.D. and M.Ch. in the Queen's University, Ireland, in 1870, and entered the army as assistant surgeon on April 1st, 1871, attaining the grade of brigade surgeon Lieutenant-colonel on December 7th, 1895, and retiring on January 19th, 1902. During the old regimental days he served in the 51st Foot, now the King's Own Yorkshire Light Infantry. He took part in the Sudan campaigns of 1885-86, in the Egyptian Frontier Field Force, receiving the medal and the Khedive's bronze star.

Universities and Colleges.

UNIVERSITY OF OXFORD.

At a congregation held on May 22nd the degree of B.M. was conferred upon A. C. Gairdner.

UNIVERSITY OF CAMBRIDGE.

At a congregation held on May 21st the degrees of M.B., B.Chir. were conferred upon P. O. Davies.

UNIVERSITY OF LONDON.

A MEETING of the Senate was held on May 19th, when the Vice-Chancellor (Professor E. A. Gardner, Litt.D.) was in the chair.

The University Chair of Physiology, tenable at the London School of Medicine for Women, now held by Dr. Winifred C. Cullis, D.Sc., will henceforth be known as the "Sophia Jex-Blake Chair of Physiology in the University of London."

Dr. Francis J. Browne was appointed as from July 1st to the University Chair of Obstetric Medicine, tenable at University College Hospital Medical School. From 1906-19, while in general practice in a Welsh mining district, he attended post-graduate courses in London and Edinburgh, and in 1914 obtained the F.R.C.S.Ed. In 1919 he graduated M.D.(Aberd.) with highest honours and was appointed senior resident medical officer and research pathologist at the Royal Maternity and Simpson Memorial Hospital, Edinburgh; he was also assistant in and later in charge of the ante-natal department created by the late Dr. J. W. Bellamy. He was subsequently appointed assistant physician in the Maternity Hospital, lecturer in clinical obstetrics in the University of Edinburgh, and clinical tutor in gynaecology in the Royal Infirmary, Edinburgh. In 1925 he obtained the degree of D.Sc.(Ed.) and in 1926 the M.S., was appointed to represent the University of Edinburgh in June next, and Dr. R. A. Young, C.B.E., was elected the representative at the twelfth annual conference of the International Association for the Prevention of Tuberculosis to be held in Glasgow in July.

The Dunn Exhibitions in Anatomy and Physiology were awarded to A. M. Easton, an internal student of St. Thomas's Hospital Medical School, and D. F. Ogborn, an internal student of University College, respectively.

On the recommendation of the School Committee of University College Hospital Medical School, G. Payling Wright has been appointed to the Graham Scholarship in Pathology for two years from October 1st.

Dates of Examinations.

In view of the termination of the strike the decision (JOURNAL, May 8th-15th, p. 851) as to postponing the examinations normally held in June and July has been reviewed. The following examinations are postponed for one week from the dates mentioned in the regulations: The first examination for medical degrees, and the second examination for medical degrees, Parts 1 and 2, examinations in dentistry, and examinations in veterinary science. No change will be made in the dates of the examinations for scholarships, the matriculation, and the examinations for M.D. and M.S.

Principal Officership.

The Senate has appointed Dr. Thomas Franklin Sibly, at present vice-chancellor of the University of Wales, to be principal officer of the University of London, in succession to Sir Cooper Perry, who retires from the office on August 31st next. Dr. Sibly is a geologist. He graduated B.Sc.(Lond.) in 1903 and D.Sc. in 1908; he is also D.Sc. of the University of Bristol. He was appointed lecturer in geology in King's College, London, in 1908, and professor of geology, University College, Cardiff, in 1913. In 1918 he went to Newcastle-upon-Tyne to occupy the corresponding chair. He became the first principal of University College, Swansea, in 1920, and still holds that appointment.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH.

THE following 20 successful candidates, out of 58 entered, having passed the requisite examinations, have been admitted Fellows:

John Croyghton A.
Cameron, John

Harold Douglas
Heslop, Andrew
Heslop, Andrew
Heslop, Andrew

Subst.

Medical News.

OF recent years there has been a steady increase in the number of large industrial concerns in this country employing medical men and women to advise the management regarding factory hygiene, the prevention of avoidable accidents, illness, and industrial diseases, and to assist in promoting the general well-being of the staff and workpeople. The Council of Industrial Medicine, an association of British industrial physicians and surgeons, already has over forty members; it meets for discussion on the fourth Friday in each month at 12, Stratford Place, London, W.1. It is also the British section of the International Congress on Industrial Accidents and Diseases, which held its fourth meeting in Amsterdam last autumn, and will, it is hoped, meet in London at some future date. The council is anxious to co-operate with all British medical practitioners (at home and abroad) who are specially engaged in industrial medicine. It is aware that there are still a number of medical practitioners in Great Britain giving general or special medical services to industrial concerns with whom so far it has not succeeded in getting into touch, and will be grateful if any such will write to the Secretary, Council of Industrial Medicine, Federation of Medical and Allied Services, 12, Stratford Place, London, W.1.

THE Right Hon. Neville Chamberlain, M.P., Minister of Health, will distribute the prizes at the London Hospital Medical College on Monday, June 28th.

THE complimentary dinner to Sir St. Clair Thomson, President of the Royal Society of Medicine, which has been arranged by the Section of Laryngology, will take place at the Hotel Victoria, Northumberland Avenue, W.C.2, on Friday, June 4th, at 7.30 p.m. The dinner will be followed by a dance. The price of the dinner and dance, exclusive of wine, is 21s. Fellows and members of the other Sections of the Royal Society of Medicine are asked cordially to support the Section of Laryngology by applying for tickets for themselves and their guests (ladies may be invited). Applications for tickets should be addressed to Mr. Norman Patterson, 82, Portland Place, W.1.

THE annual dinner of the Harvelan Society of London will be held at the Connaught Rooms, Great Queen Street, on Thursday, June 17th, at 8 o'clock.

SIR ROBERT JONES will read a paper to a meeting of the North-Western Tuberculosis Society at the Medical School, the University, Manchester, at 3 p.m. on Friday, June 4th, on some notes on the treatment of tuberculous joints. All medical practitioners who are interested are cordially invited.

THE annual general meeting of the governors of Epsom College will be held at the offices, 49, Bedford Square, W.C.1, on Friday, June 25th, at 4 p.m., when the voting for the pensioners, foundation scholars, and an assistant will be announced.

THE appointment of Dr. B. P. Watson, at present professor of midwifery and diseases of women in the University of Edinburgh, to be professor of obstetrics and gynaecology in Columbia University, and director of the Sloane Hospital for Women, New York, is now officially announced. Professor Watson will leave Edinburgh about the middle of August.

A SHORT course of lectures on functional nerve disorder will be given at the Tavistock Clinic, 51, Tavistock Square, W.C.1, commencing on June 14th, at 4.45 p.m. Dr. W. Langdon Brown will give the first of four lectures on the endocrines and general metabolism in the psychoneuroses. The course includes six lectures on the psychological factor in general practice by Dr. J. R. Rees and ten lectures by Dr. H. Crichton Miller on the theory and causation of the psychoneuroses. The fee for the course to medical practitioners is £2 2s. and to medical students 10s. 6d. Tickets can be obtained in advance from the honorary secretary at the clinic.

THE Fellowship of Medicine announces that Mr. Saner will give a special clinical demonstration at the Royal Northern Hospital on May 31st at 2.30 p.m. On June 3rd, at 12.45, Mr. Hepburn will commence a series of demonstrations in ophthalmology at the Royal London Ophthalmic Hospital. These surgical and ophthalmological demonstrations are open to medical practitioners without fee. From May 31st to June 12th there will be a series of lectures and demonstrations in diseases of children at different hospitals and clinics; some will be given in the mornings and others in the afternoons. The Chelsea Hospital for Women has arranged a two weeks' course in gynaecology from June 9th to 22nd. From June 7th to July 3rd the All Saints' Hospital will provide a course of instruction in genitourinary diseases, with lectures and demonstrations. From June 14th to 26th the City of London Hospital for Diseases of the Heart and Lungs will give a special course in diseases

of the chest. From June 14th to 25th there will be a special course for general practitioners at the London Temperance Hospital from 4.30 to 6 p.m. Copies of all syllabuses and of the general course programme may be obtained from the Secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1.

THE metropolitan and home counties members of the School Medical Group, Society of Medical Officers of Health, will meet at 1, Upper Montague Street, W.C.1, on Friday, June 4th, at 6 p.m., when Dr. C. N. Atleo, of the L.G.O. Health Department, will read a paper on the consultative aspect of school medical work. The meeting is open to all members of the profession.

COLONEL C. I. ELLIS, C.M.G., M.D., and Mrs. Ellis of Torquay have been presented with a solid silver salver, suitably inscribed, by the St. John Ambulance workers of Cornwall, Devon, and Dorset for their services as District Commissioner and Lady District Superintendent, respectively, of No. IX District, St. John Ambulance Brigade.

A CHEQUE for £430 has been presented to Dr. R. W. Looming in commemoration of his forty-three years' association with the Kendal Union and twenty-one years' service as surgeon to the Westmorland County Hospital.

DR. H. E. WORTHINGTON, on his retirement after more than thirty years' practice in Bircbington, has been presented by his friends and patients with a cheque for £250 and an album containing the names of 530 contributors.

THE twenty-seventh annual meeting of the Lebanon Hospital for Mental Diseases, Asfuriyeh, Beyrout, Syria, will take place at the rooms of the Medical Society of London, 11, Chandos Street, Cavendish Square, W.1, on Tuesday, June 1st. The chair will be taken by Dr. E. W. G. Masterman, chairman of the general committee, and the speakers will include Dr. R. Percy Smith, Dr. R. Fortescue Fox, and Miss Jane Gibb, matron of the hospital. Tea 4 p.m., meeting 4.30. All who are interested will be welcome.

THE eighteenth biennial conference of the China Medical Association, of which Dr. James L. Maxwell is executive secretary, will be held in Peking from August 31st to September 8th. It will meet in the buildings of the Peking Union Medical College, which is well provided with auditoriums, classrooms, laboratories, and out-patient clinics. There will be eleven sections: general medicine, general surgery, obstetrics and gynaecology, ophthalmology, oto-laryngology, and anthropology, physiology, public and pathology. General and sectional meetings will be given in the mornings, and demonstrations and clinics will be given on the afternoons of alternate days. Special attention will be directed to public health questions and there will be public lectures each evening. Trips to interesting buildings and localities in the neighbourhood are being arranged for the free afternoons. Business meetings and elections will occupy the last two days of the conference, and a special trip to the Great Wall of China has been arranged for September 9th.

MR. HENRY KIMPTON announces for early publication a volume on *The Thyroid Gland*, by Dr. Charles Mayo and Dr. Henry W. Plummer.

THE number of cases of measles notified in Edinburgh has been rising, and in the week ending May 15th 144 were notified as compared with 39 in the previous week.

THE Atlantic Transport Line, which previously adapted the steamship *Minnekahda* for tourists visiting New York, has introduced further improvements and provided a large sun deck. All the cabins are reserved for third-class passengers, who have full use of the decks and public rooms. Further details of the holiday monthy tours to America arranged by this company will be found in our advertisement columns.

THE Italian Pediatric Society has offered prizes for the four best monographs on the physiology and pathology of infant feeding. The first two prizes are 2,500 lire and the next two 1,500 lire. Candidates should send three copies of their monograph to La Presidenza della Società Italiana di Pediatria, S. Andrea delle Dame 21, Naples, before December 31st.

THE fiftieth congress of the German Surgical Society was held in Berlin under the presidency of Professor Friedrich Körte on April 1st, when the opening address was delivered by Professor von Eiselsberg of Vienna on the problems of the surgery of the brain and spinal cord.

THE seventeenth congress of the German Röntgen Society was held last April in Berlin, when papers were read on prophylactic irradiation of the thorax after operations, the favourable results of irradiation of the bone metastases of carcinoma, the good effect of irradiation on cerebral tumours, and irradiation in mental and nervous diseases in children.

DR. J. B. RIEUX, of the Val-de-Grâce Military Hospital, has been nominated professor of clinical medicine at the Lille Faculty of Medicine.

QUERIES AND ANSWERS.

UTERINE FIBROIDS.

"W. H. M." asks where he can find a history of uterine fibroids.

* * We have referred this question to Dr. Herbert Spencer, who has been good enough to reply as follows:

"Fibroid" is a modern word for a tumour which may be a *myoma*, a *fibroma*, or, more usually, a *fibromyoma*. The German word is *myom* and the French *fibrome*. In all three languages the word is often applied inaccurately from the pathological point of view. The ancient writers used the word *scirrhus* for a uterine fibroid. Your correspondent will find many references to this tumour in Spach's *Gynaecia* (1597); for example, Hieronymus Mercurialis (Cap. XIX) divides *scirrhus uteri* into two varieties, one of which (*legitimus*) is a "fibroid," the other (*spurius*) is due to inflammation. "And the signs of these *scirrhi* are these: For if the disease is situated in the fundus of the uterus, the uterus will always incline towards that part, where there will appear a tumour with hardness; and sometimes pain will be present (to wit, in the spurious form), and sometimes there will be no pain (in the genuine form)." Mercurialis refers to Soranus, Paulus Aegiacus, Moschion, and Avicenna.

INCOME TAX.

Motor Car: Improvement.

"H. G. P." replaced his touring car by a saloon of the same make. The local inspector refuses to allow more than the net cost of replacing the old tourer with a car of similar make and design.

* * The inspector's attitude is technically correct. The Income Tax Acts do not permit of the deduction of expenditure of a capital nature, and no allowance can therefore be claimed for outlay on improvement of the professional equipment.

Motor Car Depreciation, etc.

"B" has been supplied with detailed figures showing the alterations which the local inspector of taxes claims to make in the computation of the replacement allowances of the years entering into the average for 1925-26 and 1926-27 if "B" claims the depreciation allowances, on the ground that replacements and wear and tear allowances cannot be claimed concurrently.

* * We were under the impression that the Board of Inland Revenue had conceded the point that the "replacement" adjustment need not be made as regards the computations of profits for years prior to 1925—perhaps "B" can induce his local inspector of taxes to ask for specific advice from his headquarters on that point. There is, however, another side to the matter; in making a calculation of the "obsolescence" allowance (which it is agreed can be made concurrently with the depreciation allowance) the inspector has apparently deducted sums representing the annual wear and tear in the years when no depreciation allowance was legally due. That course is correct if the object is to arrive at the appropriate wear and tear for any particular year, but is incorrect if applied to an obsolescence claim. That claim is governed by Rule 6 (7) of the rules applying to Cases I

and II, Schedule D, and provides for the deduction of "the total allowances which have at any time been made . . . on account of the wear and tear." As no such allowances "have . . . been made," no such sums should be deducted, and on that basis it will, no doubt, be found that the old figures representing the years' profits will remain substantially unaltered.

LETTERS, NOTES, ETC.

A RISK OF YELLOW MERCURIC OXIDE OINTMENT.

"A. S. G." writes to warn practitioners against ordering the application of yellow oxide of mercury ointment to the eyelids of patients suffering from blepharitis who happen at the same time to be taking iodine in any form. My personal experience, he writes, is that the ointment is thus rendered highly irritating, so that it may cause very intense discomfort. A week after leaving off the ingestion of iodine I found it possible to apply the ointment without setting up acute irritation, but even then it was not altogether anodyne, showing, I take it, that traces of iodine were still present in the humours. This reminds me to say that the smarting caused by instillations of solutions of zinc or copper sulphate in collyria can in great measure be avoided by using a saturated solution of potassium chlorate instead of pure water as the vehicle.

THE TIME MOST FAVOURABLE TO IMPREGNATION.

G. A. . . . in the case published under the title of "artificiosa," in the **JOURNAL** has chosen for the attempts at the catamenia. This corresponds with the common Gentile belief as to the most favourable time for impregnation, but is contrary to the Jewish rules as recorded in Leviticus (chapters xii and xv). At one time I had charge of many Jewish patients, and questioned a rabbi as to the reason for the lower rate of mortality among Jewish infants. He ascribed it largely to the observance of the Mosaic regulation of continence not only for the seven (or more) days of the actual catamenial period but also for seven days after. I am accustomed to instruct my patients that the time which gives the best chance to the child that is to be is during the third week of the menstrual cycle, counting from the first day of the menstrual week. Obviously the menstrual week is unsuitable; the following week the mucosa is immature, the third week it is mature, and the fourth or pre-menstrual week it is degenerating ready for its declination.

POSTURE IN HEALTH AND DISEASE.

MR. F. MATTHIAS ALEXANDER writes: I have read the article in your issue of April 17th (p. 690) on "Posture as a factor in health and disease," by Dr. Mand F. Forrester-Brown, and for the benefit of all interested in this subject I wish to draw attention to her statement that "as Dr. Goldthwait points out, the development of force in a particular muscle or muscle group is of little value; what is important is to teach co-ordination." I find that the instructions given in the series of corrective exercises "designed by Dr. Goldthwait" quoted in the article are not in keeping with the principles and procedures involved in the teaching of co-ordination. Take, for instance, the one headed (2) stretching lateral abdominal muscles:—"First movement: Slowly shrug up one shoulder, etc.; second stage: slowly relax, if possible, leaving the ribs up, while the shoulder sinks down, etc." No subconsciously controlled person could carry out such instructions without increasing the malco-ordination and maladjustment already present.

THE USES OF VACCINES.

DR. M. W. BROWDY (London) writes: Professor Ledingham's lecture and your comments in the **BRITISH MEDICAL JOURNAL** of May 8th and 15th are worthy of serious attention. Specific vaccine therapy is a misnomer. In the *Lancet* (April 28th, 1923) I recorded results obtained in the treatment of gonorrhoea by a non-specific protein, surpassing those resulting from the use of specific vaccines, and suggested (*Therapeutic Gazette*, November 15th, 1923) that any benefit that accrued from detoxicated vaccines was contained, understood, and conditions is very disturbingly "fic vaccine" therapy. In combination of protein therapy and arsenobenzols often gives satisfactory results, irrespective of the source of the protein used.

A SIMPLE MODIFICATION OF THE MIDWIFERY FORCEPS.

Correction.

IN Dr. J. Haig Ferguson's paper, published in the **JOURNAL** of May 22nd, for "lacets" (p. 860, col. 2, last paragraph, and p. 862, second last paragraph of the paper) read "lacs."

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 33, 34, 35, 38, and 39 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 36 and 37.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 195.

An Address
ON

WHY HYGIENE PAYS.*

BY

ANDREW BALFOUR, C.B., C.M.G., M.D.,

DIRECTOR, LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

Not so very long ago the title of this address would probably have read "Does hygiene pay?" but I think it may safely be affirmed that nowadays no educated person has any doubts on that subject. He knows hygiene does pay. If he does not, his ignorance can scarcely be due to lack of being told or to absence of proof. It is the result of indifference, or a wilful blindness, or prejudice like that of the people who say "What was good enough for our fathers and grandfathers is good enough for us," or, worse than all, antagonism to anything savouring of science or scientific endeavour. Believe me, persons with those traits of mentality exist to the detriment of themselves, their neighbours, and the communities which unfortunately have to harbour them. I trust that they are unknown in the British West Indies, but I would not be prepared to lay a wager on their absence. Still, let us hope that, even if they are present, they constitute a minority, for otherwise the outlook for one of the oldest and fairest and most interesting parts of the British Empire would be distinctly unfavourable.

Nothing can be more certain than that, under modern conditions, the race is to the fit, to the people with energy and enterprise, possessing keen, active minds, blessed with sound, wholesome bodies. The motor car which rules the road nowadays is that with the best engine, the most competent machine; and the human body is a machine which, unless it be initially free from defects, and unless it is kept in good trim, will sooner or later break down. In these days of stress and strain and competition there is no place for inefficiency except the almshouse, the hospital, the sanatorium, the poorhouse, the graveyard, or the crematorium. What is true of the individual is true of the colony, and it is specially true of colonies which have to labour under certain initial disadvantages like those we find in the tropics—places where malaria is rife, where the hookworm saps vitality, where typhoid fever, a disease which has almost vanished from England, still lingers and still slays, where dysentery makes wrecks of men and women, and where, in addition to the diseases of hot climates, such maladies as tuberculosis and the venereal complaints are rife, together with many other ills to which flesh is heir, thanks largely to human ignorance, neglect, selfishness, sloth, and folly.

Now, for a race to be fit and to keep fit, certain fundamental rules must be followed, and there must also be an application of the knowledge, the scientific knowledge, which has been wrested from Nature by devoted workers, and of that other knowledge which is the fruit of experience, and which not infrequently is found amongst so-called savage and heathen communities, while conspicuously absent from those who consider themselves civilized.

Granted that hygiene does pay, and pay handsomely, how or why does it pay? It would be very easy to answer that query if I were to confine myself to the revolution which hygiene has effected in this country and the United States. Facts and figures could readily be furnished to show how it has saved life; how it has lengthened life; how it has protected and strengthened those greatest assets of any country, its children; how it has guarded the expectant mother and increased her chance, both of life and health; how in many different ways it has permeated industry and has not only protected the workers but has shown how, by applying physiological knowledge, output can be increased and fatigue lessened; how it has demonstrated that money can be saved by adopting certain lines of sanitation, and that, in some cases, money can even be made thereby, as witness the profits accruing from feeding town refuse to

hogs. These are only a few of the directions whither we may look for proofs, but it is perhaps not quite so easy to obtain the latter from places like the West Indies and British Guiana.

For one thing, these outliers of empire are in the tropics, and hygiene has not had quite such a long run for its money in the tropics as in a country like England. For another, it has not been given the same chance. For yet another, trustworthy statistics are not so readily available. Even so, however, evidence can be obtained that the progress of hygiene in British territories washed by the Caribbean has resulted, not only in putting a stop to heavy losses, but in a material gain. For this purpose it is necessary to invoke the historical perspective. Unless we have some idea of the conditions which used to prevail and the drain of men and money, owing to disease, from which these colonies were wont to suffer, we cannot fully realize the change which increased and more accurate knowledge has brought about, both from the medical and the economic standpoint. Now one of the most instructive, if not one of the most agreeable, things you can do in any of the West Indian colonies is to visit one of the old cemeteries and study the inscriptions on the graves. A similar form of education or recreation can be pursued in connexion with the mural tablets in parish churches, and sometimes is made easy for you in the form of a public monument.

What strikes one at once in the cemeteries is the number of graves of children and also of young adults who died of "fever." In many cases the inscription definitely states that yellow fever was the destroyer. Moreover, most of those who thus perished were white people, educated people, precious lives which were lost to the colony. Human life has a definite monetary value. "In 1900 it was estimated that in England and the United States the economic value of a healthy male infant at birth might be reckoned at £5; at 10 years of age, when he had survived the years of high mortality, this amount had risen to £200, and at the economically reproductive period at the end of the second decade, £500." The lives of Europeans who died in the old yellow fever days might certainly be rated as high, if not higher.

But yellow fever caused loss of money not only by killing its human victims but by dislocating trade and leading to the imposition of all kinds of restrictions. Read the old records, and you will find accounts of ships hung up in port because their crews had perished from yellow Jack. In some cases their cargoes, of a perishable nature, were ruined. Again, ships frequently could not be loaded or unloaded because no one was left to supervise. The stevedores were like sheep without a shepherd, the shepherd being either jaundiced or dead.

New yellow fever has vanished. It is true that, in some places—as, for example, St. Thomas and San Domingo—it disappeared without any action being taken, a curious state of things to which we do not yet possess the clue; but, in the main, it has come to an end because hygienic measures have trodden hard upon the heels of scientific knowledge. Once Reed and his colleagues, working gallantly in Cuba, had incriminated the "tiger mosquito," and shown that there was no other means of spread, the way was clear. For the most part the British colonies have benefited more or less indirectly, as, unfortunately, it cannot be said that, as a whole, they have bestirred themselves unduly in the fight against the mosquito concerned. I know to my cost that in 1914 it swarmed in St. George's, Grenada, and flourished in Barbados, while it still persists in both islands. Trinidad, nearer old endemic centres in South America, has done better; indeed, Port of Spain is a notable example to be followed in this as in other respects. The energy of the Americans and the stimulating influence they have exerted on Brazilians and other South and Central American nationalities possessing sea-boards has, however, cut off the supply of infection. At Rio, at Santos, and elsewhere, the yellow fever mosquito has been so reduced in numbers that it is no longer a source of danger, and now South American ports on the Atlantic, Caribbean, and Pacific coasts are free from yellow fever.

The white community is not, and has practically never been, in a majority in the West Indies and British Guiana,

* Delivered to the delegates attending the West Indian Conference held in London on May 18th. It has been abridged for publication here.

and it is true that the whites suffer to a greater extent and more severely from yellow fever than do the coloured population. But the latter have their own trials and tribulations as the result of preventable disease, and they also have a monetary value. In the old slave days this was easily obtainable.

We know that in the eighteenth century the price of negro slaves ranged from £18 to £50, and that when slavery was abolished the compensation grant to planters was at the rate of a little over £20 per slave. White slaves—political and other offenders—were known as forty-pounders, each being considered worth a sum of two score pounds. Now in these old days dysentery was terribly rife amongst the slaves. It killed them and it crippled them. A slave with acute dysentery could do no work at all, while a slave with chronic dysentery was little better than useless. Again, owing to unhygienic conditions upon the slavers, ophthalmia sometimes ran riot amongst the cargoes of black ivory and blinded the unhappy Africans. A blind slave passed from slavery to pauperdom and dragged out a miserable existence financed by the colony. Happily, there are now no slaves, but there is still labour. In some of the West Indies and in Bermuda a considerable percentage of the potential labour is put away underground in the form of dead babies. Fortunately, in some of the colonies it has been recognized that this kind of thing is wasteful as well as wicked, and now in British Guiana and Trinidad and St. Kitts, to take three outstanding examples, there are baby-saving leagues, and a serious and successful effort is being made in the direction of infant welfare work. What, however, is the good of saving infants if, as soon as they become toddlers, they acquire hookworm infection from running about with bare feet on a soil polluted with human excrement and which contains the larvae of that intestinal helminth? What is the sense of spending money to rear them if, just about the time they are due to become wage-earners, they develop the cough and blood-stained sputum which tell the sad tale of pulmonary tuberculosis, due, in all probability, to defective and insanitary housing conditions? Hygiene pays only when its principles are carried into effect thoroughly and sensibly.

There is a tendency towards complacency, towards saying, "Well, anyhow, we've done very well in this or that particular"; but, believe me, it is essential, if the best results are to be secured, if the greatest saving is to be effected, to take a wide view and endeavour to bring about a general improvement in all important directions. Of course, money may not be available for any such universal development. Then the investment should be made in hygienic stock which is sound, unlikely to depreciate in value, unlikely to be affected by movements of the disease market—in short, in gilt-edged securities like the "Prevention of Soil Pollution," unlimited, and the "Provision of Pure Water," limited only by the needs of the people and the state of the colony's finances.

Prevention of soil pollution is the best of the hygienic investments. It need not cost a great deal, and the results are widespread, for, properly carried out, it safeguards water supplies and checks fly-breeding, thus controlling typhoid fever, dysentery, diarrhoea, and, where it occurs, schistosomiasis, the fluke disease associated with the presence of blood in the urine. It also abolishes another and much more important worm disease, that ankylostomiasis or hookworm malady which the Americans have been helping us to fight in so many of our West Indian possessions, and, which, when severe, does so much harm to agricultural labour. It also lessens the incidence of worm infestations generally, and this is a most important matter, for the ordinary round worm is by no means a harmless parasite, tapeworms are often a source of illness, and there can be little doubt that whip-worms and thread-worms and all the rest of that unpleasant crew, if they do not actually cause sickness, keep people below par and militate against the ideal state of health and fitness. It is interesting to note that in the Philippines the question has recently been raised if ascariasis, or round-worm infection, may not be an exciting cause of nephritis, a condition very prevalent and causing considerable mortality in British Guiana, Trinidad, and Barbados. In addition, the preven-

tion of soil pollution by the provision of latrines and the education of the people in their use and value is to some extent an elevating force. It makes a population more cleanly and self-respecting. I admit it may take a long time to accomplish such a regeneration, for, though hygiene pays, it does not always yield quick returns. Sometimes, however, it does, and your "Provision of Pure Water" stock is likely, nay certain, to be satisfactory in this respect.

There are other stocks worthy of consideration. I can strongly recommend "Anti-Mosquito," unlimited—that is, not limited to the anophelines which carry malaria, but extended to *Culex fatigans*, the carrier of filariasis with its sequel elephantiasis, and the other domestic gnat, *Aedes aegypti*, which, as we have seen, carries yellow fever, and which is also responsible for dengue or dandy fever, a distressing complaint which still breaks out now and again in the New World.

Malaria is the curse of places like Trinidad, British Guiana, and Jamaica, while it also causes much invaliding in some of the smaller islands. It is true that in certain localities antimosquito measures are impracticable—the game is not worth the candle; in other words, the results would not be commensurate with the money which would have to be spent. This applies to places where engineering works—draining, filling, and so forth—are required. But there are many spots where a reasonable expenditure pays hand over fist. Who can estimate the saving in hard cash which the antimalarial measures in Port of Spain have effected? Remember that malaria is not only a crippling disease, it is a killing disease.

Dr. Maynard, in a very interesting paper on "The economic aspect of preventable deaths," which embodied the results of an inquiry into the financial loss due to unnecessary mortality in the Transvaal, a paper published in 1908 in the *Transvaal Medical Journal*, enters mathematically into the loss sustained at that time by the Transvaal every year from deaths due to four preventable diseases—namely, typhoid, dysentery, pneumonia, and tuberculosis. It amounted to no less than £2,640,000. Dr. Maynard, however, does not forget to quote Lord Playfair's words:

"The record of deaths only registers as it were the wrecks that strew the shore, but it gives no account of the vessels which were tossed on billows of sickness, strained and maimed as they often are by the effects of recurrent storms."

The crippling effect of disease is perhaps exemplified better by tuberculosis than by any other malady, because, except in the acute pulmonary cases, the victim usually struggles along for some considerable time, waging a fight with Koch's bacillus, which, alas! too often terminates in defeat. One of the saddest and most depressing sights I ever witnessed was a collection of ex-service men who had become infected during the war or who had relapsed as a result of strain and exposure. Damaged lives, that was what they were, some slowly struggling back to health and possibly to efficiency, some stationary, not a few doomed.

Tuberculosis is a most important disease in the West Indies because, as you know, the negro part of the population, or rather a large section of it, lives in terror of "duppies" or "jumbies" and close up all doors and windows at night. They take every precaution against imaginary dangers and are ignorant of the risks they run from that great white plague, which in very truth is "a pestilence that walketh in darkness." If you travel by tube in this city and so avoid the dangers of its thoroughfares, which, from the life-saving standpoint, are unhappily proving the truth of the refrain to the showman's ditty, what is gained upon the roundabouts is lost upon the swings, you will note that you are strongly advised to invest your money in building societies. Well, a very sound hygienic stock in the West Indies is building stock, provided that when, or rather before, you put money into good houses for the people you make sure they will not abuse them—in other words, educate them so that they will appreciate the principles of healthy living and the dangers of unhealthy dying. I say "unhealthy" advisedly, for there is a way of dying which is not unhealthy but natural, the way we should all die but do not.

So far as I am aware, no one has ever done for the West Indies what Maynard accomplished for the Transvaal, but Colonel Christophers of the Indian Medical Service some little time ago discussed the question of what disease costs India. It is true he did not get the length of actual monetary calculations, owing to the difficulties of accurate estimation in a country so large and populous, with such a diversity of governments and nationalities, creeds and castes. At the same time, he adduced some highly suggestive, not to say startling, figures, pointing out that of the 360 millions of people in the Indian Empire 7,000,000 die annually; the average inhabitant does not get a fair run of life for his money. While in England, out of every 1,000 persons born 530 attain the age of 50, in India only 186 reach what has been far from euphemistically termed the "dirty half-hundred." There is nothing to show that the natural span of life in India is a shorter one than in England. The real cause of the difference is the malign influence of disease acting in the earlier and consequently very often in the wage-earning periods of life.

Some of the conditions and diseases in India are not preventable because our knowledge regarding them is defective. The same is true of the West Indies—hence the absolute necessity for research. Here is what Christophers says on that subject:

"All I can say is that the tribute paid to disease in a country like India is one of importance economically, even politically, and one that has many financial and commercial aspects. It, however, transcends this in being of importance to the welfare of 360 million human beings, who, by their tacit acceptance of such calls as may be made upon them, signify their belief that they are being governed to the best ability of those responsible for such government. The important matter, therefore, seems to be that proper and enlightened views should be held by Government as to the steps to be taken to justify that trust, in so far as the prevention and amelioration of disease is concerned.
